12 More Cheap Talk
Here's the beginning of the end of your sanity—a text-to-speech algorithm that lets your computer speak its mind! WB6NQK

22 Try an Inverted-Psi Wire
Get the DX edge on 80m with a radiation angle that's almost *too* low! W1GV/4

28 Seleal and State Machines
WA7NBF takes the mystery out of this powerful technique with a hands-on selective-calling project. WA7NBF

36 Little or No Resistance
Explore the strange world of superconduction, where current flows forever and a picosecond is an eternity. AJ0N

40 Run Silent, Run Beep
Is your FT-227RB scanning? You won't have to guess with this easy add-on. PY2AUC

42 A Better Money-Maker
WA6TTY stiffens up his original power supply to deliver a solid 13.8 volts at 20 Amps. The cost? Under three bucks! WA6TTY

44 The Commodore Cable Caper
Need a printer cable? Strapped for cash? Don't just sit there—*build* the durn thing! KE4PC

46 The Perfect RTTY Filter
Its tunable shift covers 80 to 1160 Hz with a flat gain and Q. And you can build it for less than ten dollars! WA0MRG

50 Double Your Computing Power!
Try "parallel processing" with a second CoCo keyboard. NO8M

54 Working 2ICTU
Can RTTY get any simpler? WB8OMK

WHAT?

News from KW1O

Four things happened recently that set alarms clanging in my mind. Taken separately they seem innocuous enough, but it really wasn't until the fourth incident that I remembered the other three things and they all came together in a pattern. Here's what happened, in no particular order:

- On the local packet bulletin board I see a product release for TAPR's new TNC-2. It gives a technical description of the unit, a price, and an address and a telephone number to write or call if you want to buy a TNC-2.
- Lee Shoblom asks the FCC to let him use the 432-MHz ham band to gather news for his low-power television station.
- Chet Lambert of *Computer Trader Magazine* announces his Packet Sweepstakes—a Worked-All-States contest that promises valuable prizes to the winner.
- During the Mexico City earthquake, television networks use amateur radio to coordinate production schedules and to order parts and equipment.

Dingdingdingding!

There are two types of trouble here. In the first, a person or organization outside of amateur radio is trying to use the hobby for personal gain. In the second, the threat is from within our ranks, but the goal is the same. Commercialism, external and internal.

Outies...

External commercialism is something we can deal with easily. They FCC gives us plenty of time to comment on petitions that might affect ham radio adversely, and the ARRL does a pretty good job of keeping us all informed.

The Mexican earthquake made it obvious that the Commission had rather vaguely defined the rules of conduct during a communications emergency. In fact, they had rather vaguely defined a communications emergency. The major news organizations pounced on the loophole *before* the earthquake, and the League pounced on the **FCC**, asking for a reconsideration of the rules. What went on *after* the quake is a travesty. Fortunately the Commission agrees and I don't think it will happen again.

Now, take Lee Shoblom. Here is a fellow who owns a television station out in the boonies and wants to use ham radio to transmit video back to his studio. Can you blame him? Why should Lee shell out **$30,000** for a remote link when he can buy a Creepie Peepie and some ham gear for five hundred bucks? The best part is this: The local amateurs think it's a *wonderful* idea. Well, I think it *stinks*. We might as well hand over the keys to our UHF spectrum. And while we're at it, we could give cabbies the two-meter band (I hear they're already using it in New York). Since this is external commercialism, we have plenty of time to examine what's going on and to act appropriately.

...and Innies

Internal commercialism is more insidious. It's a lot harder to define. And because it is perpetrated by people we know, we're less likely to call it out. But that doesn't make it OK.

The spread of internal commercialism is directly linked to the growth of packet radio. The reason is simple: The act of communicating has shifted from the radio to the keyboard. What appears on the screen of your terminal is the same whether you use a VHF channel or a telephone line for the connection, so it seems very natural to transfer information from one computer to another.

The "ad" I saw for TAPR's TNC-2 was probably lifted from CompuServe® and deposited on our local packet bulletin board. In fairness, I must point out that its "wrongness" was felt by several individuals who read it, and it was eventually removed from the airways. But how do we know if something is commercial? In the TAPR case the matter was clear-cut, but consider this: A message is placed on a packet board which announces the availability of a new piece of hardware. No price is given, but an address is supplied so that you can get more information. Commercial? I say that it is, because the message will eventually create a sale for the company producing the hardware. Or try this: Excerpts from an amateur-radio newsletter are made available on a packet bulletin board. Commercial? Again, I have to say that it is, since the excerpts could be considered an advertisement which would make a sale for the publisher. This kind of internal commercialism is going to get worse as our hobby matures unless strong measures are taken *now*.

Finally, Chet Lambert's Packet Sweepstakes. I group this under Internal commercialism because Chet is a ham who dearly loves amateur radio, not some sinister corporation trying to hoodwink us. Nevertheless, the idea still smacks of commercialism. Look—if someone is willing to give you a VHF transceiver for working 50 states on packet radio, how long will it be before you can get a Buick for winning the *CQ* WW PX contest?

Reaction to the Sweepstakes, at least here in New England, has been negative among experienced packeteers. And I

SOS DE USQS

THERE'S BAD NEWS from Laryl KM7Z at the **United States QSL Service (USQS)**. The bad news is that USQS is no more. For those of you not in the know, USQS was an incoming United States QSL bureau, handling DX *and* stateside cards. I don't imagine that the volume of DX cards coming in was very high (the ARRL bureaus have that end locked up), but the beauty of USQS (and the reason W2NSD/1 kept envelopes there) was the fact that *stateside* hams could send cards to *other* stateside hams in bulk. For free. In fact, if you sent along a few dollars for postage, Laryl would *look up* addresses for you and mail the cards out! Luckily, **Bill Wellborn K4CLA** has stepped in to fill the void with **KIQS** (Bill says to pronounce it "kicks"), which stands for the **K4CLA Incoming QSL Service**. Here's how it works: Send Bill a dollar for four stamped envelopes, which he will keep on file. Sort your outgoing (US only!) cards by call area, then alphabetically by suffix and send them to KIQS. Bill stuffs the on-file envelopes and sends cards out four times a year: in January, April, July, and October. The address for KIQS is 562 Oak Drive, Lexington SC 29072-9059. Laryl's USQS is returning all unused SASEs to their owners.

Hot Shots

IS IT TIME to start a monthly magazine called *Hams In Space*? It seems likely, with the announcement of two more possible missions. In March, 1986, **Dr. Ron Parise WA4SIR** will be aboard shuttle mission 61-E (Astro-1) as a Payload Specialist. Dr. Parise is an astronomer and will be making observations of Halley's Comet and other celestial objects. Ron has let NASA know that he would like to operate a packet-radio station from the shuttle; another first for ham radio! AMSAT is working with Ron in coordinating the operation. **Dr. Owen Garriott W5LFL**, America's first ham in space, is scheduled for a flight on mission 61-K, set for a September, 1986, launch. Owen will undoubtedly seek permission to operate from space.

Look! It's . . .

HALLEY'S COMET (rhymes with tally, though some swear it rhymes with holly) is getting brighter, and the hoopla surrounding it is getting really intense. There's Halley's Comet T-shirts, Halley's Comet Expeditions ($1,500–$5,000), "special" Halley's Comet telescopes, and so on. Don't think that hams have been forgotten; there is now a Halley's Comet Radio Watch. Project coordinator **Tania Miller WB9TKC** is looking for reports of unusual conditions on all bands, including amateur and CB frequencies, shortwave broadcast bands, and television channels. Your report should include the frequency (or band), time, date, your location, and the abnormal condition. Tania is offering a Comet QSL for your trouble. Because of the enormous hype surrounding the comet's return, many people are expecting a spectacular celestial event, complete with a fiery comet that is visible even during the day. 'Tain't so, friends. You'll need expert advice on where to *look* for the thing, and even then you'll need to look *very closely* to find it; a trip to your local book shop for a Halley's Comet manual (there are about a hundred of them) is in order. And don't rush out and buy a high-priced telescope, no matter *what* the ads claim. The best thing to use is a pair of low-power binoculars.

County Bounty

ARMADILLO COUNTY, TEXAS, has been created by a proclamation from Texas Governor Mark White. Between March 2 and December 31, 1986, any amateur operating along the Texas Independence Trail may give his QTH as Armadillo County, Texas, in order to celebrate the state's sesquicentennial. The **Texas DX Society** will be setting up operations along the trail throughout the year to give everyone a chance to work the new county. And Armadillo will be on the air during the massive **1986 Armadillo Run**, an attempt by the TDXS to activate *every county in the United States* (3,077!) during the 1986 County Hunters phone and CW contests (phone on May 3–4 and CW on July 26–27). These guys are really going to pull it off—they've spent the last year or so setting up regional and sectional coordinators all across the country. In 1983, club members operated from every county in Texas (254 counties). In 1984, the project expanded to cover Texas, Arkansas, Louisiana, and Mississippi! If you want up-to-the-minute information about the 1986 Run, get in touch with Tom Taormina K5RC, 3940 Bahler Avenue, Manvel TX 77578.

Texas Governor Mark White (center) creates a new county. That's KZ5M on the left and K5RC on the right. Photo by K5RVK.

Canada Tries

CANADIAN AMATEURS got some good news and bad news regarding the Canadian Radio Relay League request for early access to the WARC bands. First, the Minister of Communications said that before any privileges on the 24-MHz band were granted, commercial stations occupying the band would have to be either shut down or moved to another part of the spectrum. Also, certain amendments to the General Radio Regulations would need to be made, something that has in the past taken years to accomplish. Only a month later, the Minister announced that most commercial users of the 24-MHz band had been removed and that the process for amending the rules could begin soon. He also noted that an amendment to the Regulations was already under way to allow amateur use of the 18-MHz band, which had already been cleared of commercial users.

Goldwater Winner

THIS YEAR'S Goldwater Scholarship Award went to 18-year-old Clark Barrow KI4UT, of Cocoa, Florida. Clark plans on a career in satellite communications doing research and development. He is working at NASA's Kennedy Space Center at a job won as a prize in a science contest. Clark said that he will use the $5,000 prize to help pay for an Electrical Engineering degree from Auburn University.

Weirdness

DON'T TOUCH THAT DIAL! In fact, don't even turn on your receiver! Legislation introduced into the House of Representatives by Robert Kastenmeier (D-Wisconsin) and Carlos Moorhead (R-California) would, if signed into law, make the reception of nearly every type of radio transmission a Federal offense. The **Electronic Communications Privacy Act of**

1985. HR-3378, is the name of this travesty and its backers (mainly the cellular-telephone industry) want to make it a crime to receive any radio signal that does not fall into one of these categories: distress calls, Amateur Radio Service, Police or Fire Radio Service, CB, broadcasts intended for the general public, and walkie-talkies. What this Bill tries to do is extend the laws against wiretapping to the radio spectrum. In fact, *monitoring an amateur-radio phone patch* would be illegal under this proposal. This is obviously absurd, but the Bill has *strong support* and *not much resistance!* Sit down *right now*, write a letter to your Congressmen, and tell them that you think that HR-3378 is a direct attack on your rights as a citizen of the United States.

30 Days

30 DAYS HATH SEPTEMBER, but not exam applicants, says the FCC. You no longer have to wait 30 days before retaking a license exam that you have failed. The Commissioners felt that, "There is no persuasive evidence in the record that an applicant who has waited 30 days between tests will be better prepared for the next test than one who has waited 27 days, or 13 days, or 7 days, or any other period of time." The existing regulations covering the Volunteer Examination program already specify that questions must change from test to test, so there won't be a problem with someone taking a test on Saturday and seeing the same questions on a Sunday test. And, since each VE Coordinator creates its own tests from a large pool of questions, it's not likely that two VECs will prepare identical exams.

Who's On First?

IT LOOKS LIKE the absolute very first legal amateur signal on the new 900-MHz band was transmitted by **K9MK/R**, a repeater built by **Mike Krzystyniak K9MK/5, Bill Cantrell WD5CVG, and Greg Raven KF5N.** These guys, all members of the Motorola Amateur Radio Club, decided to beat everyone to the punch and built a complete repeater system out of surplus Motorola mobile radios in under three weeks! The machine has an input of 908.000 MHz and an output of 920.000 MHz and serves a four-county area near Ft. Worth, Texas. Another Motorola repeater can be found in Chicago on 909.000/921.000 MHz serving the northwest suburbs.

XE Permits

MEXICO IS UNOFFICIALLY granting temporary amateur licenses to US citizens visiting the country. In a story which appeared in the *W5YI Report*, **Chris Petroff N5HQN/XE2BSG** reported that the Secretariat of Communications and Transport has authorized the licenses. The temporary permit is valid for the length of the amateur's visit to Mexico as stated on his or her visa. Petroff believed that the permit was for a Class II Mexican license, which allows 250 Watts on HF and 100 Watts on VHF.

Roll 'Em

IF YOU MISSED the action during space-shuttle mission 51-F (Tony England W0ORE and John-David Bartoe W4NYZ), take heart. Copies of the tapes Tony and John-David used to log are now available from the American Radio Relay League. Just send League archivist **Karl Townsend** the date and orbit number that interests you and he'll generate the tape that you need. (You might want to write or phone first to check out prices. If you write, enclose an SASE.) Videotapes of the SSTV images sent to and from *Challenger* are also available. Robot, the company that manufactured the 1200C scan converter carried on the mission, is working "between the lines," using arcane techniques in an attempt to recover as much of the uplinked video information as possible. In many cases there were so many signals competing on the frequency that only bits and pieces of video appear on the tapes. QSL cards are available from the ARRL for two-way contacts, reception reports, confirmed reception by *Challenger* of uplinked SSTV, and so on. Send an SASE to the ARRL, 225 Main Street, Newington CT 06111.

Erratum

PAGE 82 of our November, 1985, issue contains an error. In our review of the **ICOM IC-735. N1BLH** says that the rig's microprocessor gets its instructions from a lithium-battery-backed RAM. A conversation with ICOM revealed that this is not the case. Only the memories are battery-backed: The instructions are stored in a ROM.

Prefix Mix

THE PREFIX FOR CT2 AZORES has been changed to **CU.** The number after the prefix now refers to each of the nine islands of the Azores Archipelago: CU1 Santa Maria, CU2 Sao Miguel, CU3 Terceira, CU4 Graciosa, CU5 Sao Jorge, CU6 Pico, CU7 Faial, CU8 Flores, and CU9 Corvo. CU0 is reserved for repeaters. Some CT2 amateurs now have completely different calls, while others have only a different prefix. There also is a new address for the Azores QSL Bureau: it's Associacao de Radioamadores dos Acores, PO Box 211, 9 503 Ponta Del Gada, Azores Islands.

Status Quo

GORDON GIRTON W6NLG wants the FCC not to issue any more "preferred" callsigns. His petition to the Commission requests that all 1-by-3 K and W calls be removed from the list of available callsigns until all other combinations have been exhausted. Gordon notes that many hams equate 1-by-3 K and W calls with the number of years licensed—most of those calls are held by "old-timers" and can be seen as a sort of status symbol. WA, WB, and WD calls are also covered in the petition. There's been no word from the Commission on this one, yet.

Land of OST

THERE'S A CHANCE that RM-4829 and RM-4831, the Dockets before the FCC dealing with land-mobile use of our 220-MHz allocation, are dead. **Tom Stanley**, Deputy Chief of the Office of Science and Technology, has been named to fill the OST Directorship vacated by Bob Powers. Both RM-4829 and RM-4831 were being handled by the OST, and it may take quite some time before the new administration decides what should be done about them. **Art Reis K9XI**, Editor of *220 Notes*, feels that the issue is indeed dead and that the only reason the FCC would bring out either Docket as a Notice of Proposed Rulemaking would be to resolve the question of Land Mobile Service interference to television channel 13.

Free Press

AT THE RISK of causing a strike at the *73* mail room, we're making available yet another freebie! This time your SASE will net a **Genuine FCC Emission Classification** List. No longer will you have to remember all of those silly numbers and letters like J3E, A1A, and F3E—you'll have the entire list right at your fingertips! This list is essential to accurate logging, and no ham should be without it. Get your free copy by sending an SASE to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: Emissions.

Thanks

THIS MONTH, "QRX" comes to you courtesy of *Gateway, Westlink,* the Personal Radio Steering Group, *220 Notes,* the North Florida ARS *Balanced Modulator, The VHF Journal,* and the Arizona Repeater Association *Squelch Tail.* Send your "QRX" items (photos, too!) to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: QRX. And have a great 1986!

Thomas C. Johnson WB6NQK
2056 E. Sutter Place
Oxnard CA 93033

More Cheap Talk

Here's the beginning of the end of your sanity — a text-to-speech algorithm that lets your computer speak its mind!

As promised in my article, "Talk Is Cheap" (*73*, October, 1985), I have developed a text-to-speech algorithm for the speech synthesizer I described, and in this article I will present what I came up with. Before getting into the details, let me review the basic hardware and software which make up "Cheap-Talker."

Hardware

The hardware used is an APPLE II bus-compatible circuit board. The schematic is shown in Fig. 1. It uses the SPO256 voice-synthesizer chip manufactured by General Instruments and marketed by Radio Shack as part no. 276-1784. This chip retails for $12.95. When you go to Radio Shack to purchase it, make sure you do not mistakenly buy part no. 276-1783. This also is a voice-synthesizer chip but it uses an external ROM to produce only 36 words. It also does not come with the comprehensive technical data pamphlet accompanying 276-1784. The latter will have "SPO256-AL2" stamped on it.

Cheap-Talker also uses an MC6821 parallel interface adapter for communications with the Apple bus. Port B is used to transfer data from the computer to the synthesizer. The CB2 line provides a negative-handshaking pulse whenever data is written into port B. This signals the synthesizer that data is ready. The LRQ (Load Request) line is connected to bit 7 of port B so it can be tested easily to find out if the synthesizer is ready for yet more data.

I've also used the LM386 audio amplifier as recommended in the data sheet. It works very well, providing an adequate volume for normal indoor use. This circuit can be constructed by the freehand etching of a circuit board or wire-wrapping on a protoboard. I have done both with equal success.

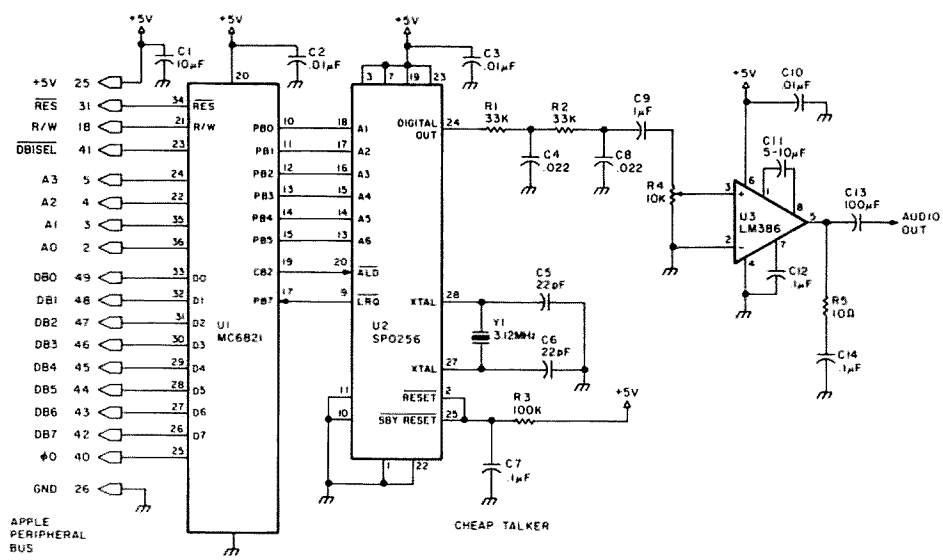

Fig. 1. Schematic of the Cheap-Talker.

Software

The software driver used to make the chip work is shown in Listing 1. The entire driver program and allophone buffer fits in just 208 bytes. The program alone is only 48 bytes. This program, when called at location $300 (768 decimal), will send the allophone codes in the allophone buffer located in locations $341-$3CF (833-975 decimal) to the synthesizer, one at a time. Location $340 (832 decimal) contains the number of allophones to be sent; it allows 142 allophone codes to be sent, which is more than enough for most messages composed of a number of words. Most words contain fewer than 20 allophone codes. Since the text-to-speech algorithm translates only one word at a time, there is plenty of room in the buffer to speak even the longest of words.

The INIT portion configures port B of the 6821 chip to have bits 0-5 in the output mode and bits 6-7 in the input mode. Bit 7 is used to monitor the LRQ pin on the synthesizer to find out when it is ready for another allophone. The CB2 pin is put in

the "pulse on write" mode which sends a negative pulse out when data is written into port B. This signals the synthesizer that the allophone data is ready.

Note that the addresses for the PIACRB (Control Register B) and PIADPRB (Data Direction and Peripheral Register B) registers are offset in lines 15 and 16 for use in slot 3 of the Apple. If you are using an assembler which uses similar nomenclature, you could change the slot by changing the $30 to $x0, where x is the slot number. If you are typing in the hexadecimal values for the program, you would change the $BF in locations $303 and $30D to $8F + $n0 where n is the slot number. You would also change the $BE in locations $308 and $327 to $8E + $n0.

The SPEAK routine takes the allophones and sends them to the synthesizer via the PRONOUNC routine. SPEAK uses the value in location $340 to initialize the Y register as a counter to keep track of the number of allophones sent. The X register is used as a pointer to the various values in the allophone buffer.

The PRONOUNC routine saves the allophone data in the accumulator on the stack while it checks the LRQ line to see if the synthesizer is ready for the next allophone. It does this by reading the value in bit 7 of Peripheral Register B which, as was mentioned earlier, is set up as an input. If bit 7 is a 0, then the synthesizer is ready to receive data via Peripheral Register B.

This simple hardware/software combination forms the basis of the speech synthesizer system I call Cheap-Talker. The text-to-speech algorithm and rules I will describe next will use it to produce unlimited speech based on English words sent to it.

Listing 1.

Algorithm

The algorithm I came up with was inspired by work done at the United States Naval Research Laboratory described in a 100-page report entitled "Automatic Translation of English Text To Phonetics By Means Of Letter-To-Sound Rules." That's quite a title, but it's also quite a fascinating report.

In this report, an algorithm and 329 rules which translate English words into the International Phonetic Alphabet (IPA) are described. The algorithm also converts IPA symbols into the phonetic codes of the synthesizer the Laboratory was using (the Federal Screw Works Votrax VS-6 audio response unit). The software developed for the algorithm was written and described in SNOBOL, and as a result I did not find it very useful in writing my algorithm for the 6502 microprocessor. I did, however, rely heavily on the rules they developed and devised my own algorithm which would utilize those rules and generate the allophone codes used by the SPO256 chip.

The algorithm I developed (called Translator) is written in 6502 assembly code and occupies 2,186 bytes. If a 16K card is available, then it resides in the card at $D000. Otherwise it resides at $7600. It is composed of 37 subroutines, each having a specific purpose. A chart showing the subroutines and their relationships is shown in Fig. 2.

Each subroutine calls upon the subroutine connected to it in the row below it to accomplish its task. For example, TRNSLATE, the main routine, calls these routines to do its job: ILLEGALS, COUNTCHR, FINDRULE, GETRULE, TESTRULE, CHKRULE, ADVRP, DEBUG, APPEND, and SPEAK. In turn, FINDRULE will call the routines PUNCT and NUMBERS, and so on.

When a word is placed in the word buffer and Translator is called, it analyzes each letter in the word and searches the rules to find those which best match the context of each of the letters and uses the allophones associated with the chosen rules to speak the word. This is done in the following manner (please refer to Fig. 3).

First, TRNSLATE calls COUNTCHR to count the number of characters in the input word string, convert them to uppercase if they are not already, and set the MSB in each one. If there are no characters in the word string, TRNSLATE is finished. Otherwise the variables CC, ALOFON, and ABUF are initialized. CC points to the currently testable character in the input word string. ALOFON points to the next position in the allophone buffer to store an allophone code. ABUF contains the current number of allophones in the allophone buffer to be spoken.

Next, the currently testable character is loaded for analysis. If it is an illegal character which can't be translated, it is ignored, CC is moved to the next character in the word string, and the next character is loaded if it is not the end of the word. If the character was OK, FINDRULE locates the rule group which pertains to the character. Then GETRULE loads sections A, B, C, and D from the rule into separate buffers. TESTRULE tests section B, then A, then C to see if they fit. All of them must pass for the rule to pass.

If the rule passed, it is checked by CHKRULE to see if it has a higher priority than any of the previous rules checked in the group. If it does, it records the address and the priority for comparison by any following rules in the group. After

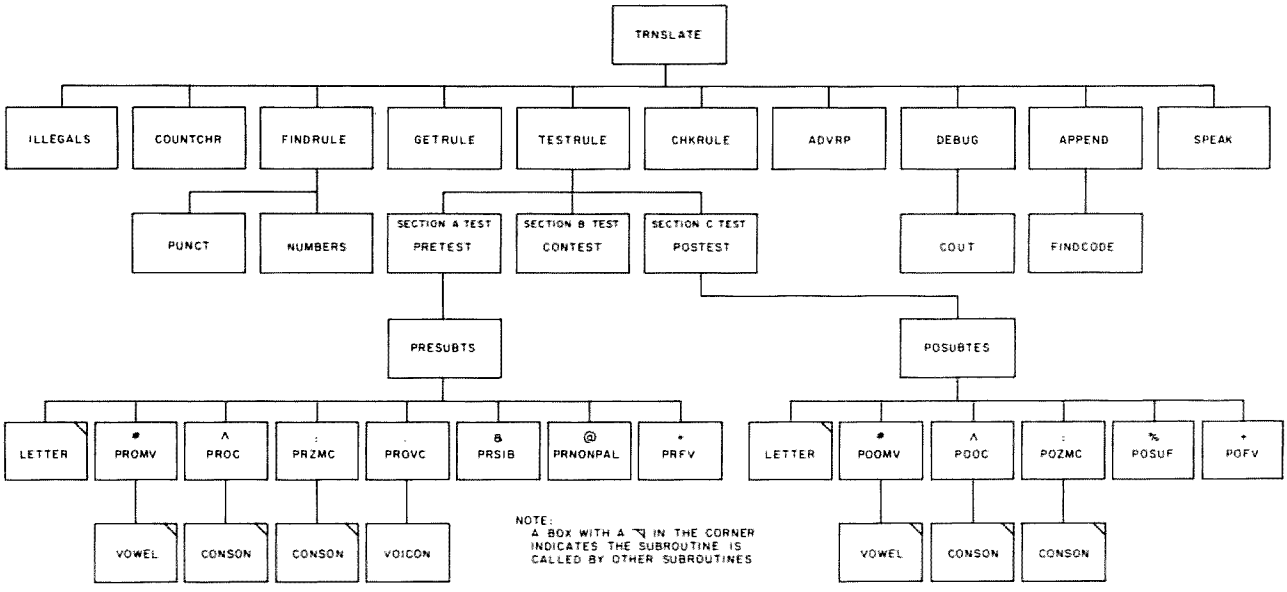

Fig. 2. Subroutine chart, translator text-to-speech algorithm.

that, or if the rule did not pass, ADVRP advances the pointer which points to the current rule in the group to the next rule. If zeros are found, the end of the group has been reached. Otherwise the rule is loaded and tested.

When all the rules have been tested and at least one of them passed, that rule (the one having the highest priority) is again loaded and the DEBUG routine is called. This routine, if the control flag is on, will send the text of the rule to the screen to show which one has been found for the particular character. If the rule included any allophones in section D (some rules do not have any, indicating the character(s) in section B are silent), they are converted to hexadecimal codes and loaded into the allophone buffer at ALOFON by the subroutine APPEND. CC is moved to the next testable character in the word string.

If it has not reached the end of the word (indicated by the presence of a $0D or a $8D carriage return code in the input word string buffer), the next character is loaded and analyzed. If it is the end of the word, the SPEAK subroutine (driver software in Listing 1) is called to send the allophones to the synthesizer.

Rules

Translator utilizes RULES in order to translate a word into its equivalent allophones. These rules occupy a total of 5,290 bytes. If a 16K card is used, then the rules reside in the card at $E000; otherwise they are at

RULE FORMAT: A(B)C = D

SPECIAL SYMBOLS USED IN SECTIONS A & C
(these represent calls to subroutines to check for the following conditions)

- # One or more vowels (A,E,I,O,U,Y)
  Used in sections A and C.
- ^ One consonant (B,C,D,F,G,H,J,K,L,M,N,P,Q,R,S,T,V,W,X,Z)
  Used in sections A and C.
- : Zero or more consonants (always passes)
  Used in sections A and C.
- . One voiced consonant (B,D,G,J,L,M,N,R,V,W,Z)
  Used in section A only.
- % Suffix (E,ER,ES,ED,ELY,ING)
  Used in section C only.
- & Sibilant (C,G,J,S,X,Z,CH,SH)
  Used in section A only.
- @ Nonpal (letters which modify the sound of long U)
  (D,J,L,N,R,S,T,Z,CH,SH,TH)
  Used in section A only.
- + Front vowels (E,I,Y)
  Used in sections A and C.

Table 2.

$7F00. These rules are ASCII text strings and are broken into 28 groups. There is a lookup table used to locate each of the rule groups. There is a group for punctuation marks, numbers, and one for each of the 26 letters in the alphabet. Each of the rules in the group is organized according to the priority of the rule, going from the highest to the lowest. A sampling of these rules is shown in Table 1 to demonstrate the format the rules take. Each rule has the form: A(B)C = D—which means "The character string B, which has a left context A and a right context C gets the pronunciation D." B is a letter or group of letters which must match exactly in the source word. A and C are either letters, strings of letters, or special symbols. The special symbols are used to call certain routines to test the appropriate contexts for whichever class of strings is needed. The special symbols used are shown in Table 2.

For example, a # means that one or more vowels must be in the same relative position in the word as the symbol is in the rule. If either A or C is not present, then this indicates that this section of the rule will always pass. A space in section A indicates the beginning of the word, and a space in C indicates the end of the word. D names the allophone codes used to pronounce the letter(s) in section B. These names are later converted into hexadecimal codes to be sent to the speech synthesizer.

As stated above, the rules in each group are organized into four subgroups according to their translation priority. This priority is determined by the contents of sections A, B, and C. Rules with criteria in sections A, B, and C have the highest priority. Rules with criteria in sections A and B and none in C come next, followed by those with criteria only in sections B and C, and finally those with only section B.

When the rules are analyzed in the translator algorithm, each rule is tested and the rule with the largest number of criteria in sections A, B, and C combined will be chosen to pronounce the letter(s) in section B. For example, if one rule had two symbols (criteria) in section A, one in section B, and two in section C (total of five) it would be given lower priority than a rule with no symbols in section A, three in B, and three in C, even though a rule such as the former has a higher priority in the rule group.

You might wonder, why not just put the rules in order of the number of total symbols they have and eliminate some code? Well, that is certainly another way of doing it, and I believe it would work just as well. In the process of writing and experimenting with this algorithm, the former method is the one I settled on; it would require a lot of rule shuffling to convert to the latter method, and there would be very little savings in terms of execution time and code space.

As with all of the computer projects attempted, I have found that for as long as I kept playing with them I would keep changing them and finding new ways to do what I was doing. With something like this, I had to pick a point where the project was satisfactory and stick with it. There is always room to improve. (Enough excuses!)

To summarize how the algorithm works and how the rules are used, let's take the word HOW and translate it into allophones. I will use the H rules reproduced below for reference. Notice the STR before each rule. This is a mnemonic for the LISA™ assembler which tells it to count the number of characters in the quotes and store it in memory at the current address followed by the ASCII codes of the characters.

```
HRULES:
; RULE GROUP FOR LETTER H
   STR "(H) = EY CH "
   STR "(HAV) = HH1AE VV "
   STR "(HERE) = HH1YR "
   STR "(HOUR) = OW ER1"
   STR "(H)# = HH2"
   STR "(HOW) = HH2OW "
   STR "(H) = PA1"
   HEX 0000 ; END OF RULE
GROUP
```

The first character in the word is H, so the rule group selected is the H rule group. Each rule is located and broken into its component sections (A,B,C, and D) and each section is put into its own buffer. The first rule selected is " (H) =EH CH ". Section B will pass because the H in the parentheses matches the H from the word. The A section passes because the H in HOW is the first character. The C section does not pass because the "H" is not the last character. Therefore the rule is not a match.

The next rule is loaded. It is " (HAV) = HH1AE VV ". This time section B does not match because the three

Little Board™ $249

The World's Least Expensive CP/M Engine

CP/M 2.2
INCLUDED

- 4 MHz Z80A CPU, 64K RAM, Z80A CTC, 4-32K EPROM
- Mini/Micro Floppy Controller (1-4 Drives, Single/Double Density, 1-2 sided 40/80 track)
- 2 RS232C Serial Ports (75-9600 baud & 75-38, 400 baud), 1 Centronics Printer Port
- Power Requirement: +5VDC at .75A, +12VDC at .05A / On board -12V converter
- Only 5.75 x 7.75 inches, mounts directly to a 5-1/4" disk drive
- Comprehensive Software Included:
  - Enhanced CP/M 2.2 operating system with ZCPR3
- Read/write/format dozens of floppy formats (IBM PC-DOS, KAYPRO, OSBORNE, MORROW...)
- Menu-based system customization
- Operator-friendly MENU shell
- OPTIONS:
  - Source Code
  - TurboDOS
  - ZRDOS
  - Hard disk expansion to 60 megabytes
  - SCSI/PLUS™ multi-master I/O expansion bus
  - Local Area Network
  - STD Bus Adapter

characters in the parentheses do not match the three characters starting with H in the word HOW.

The next rule is loaded: " (HERE) = HH1YR ". Again, section B does not match.

The next rule is the same way, but the next rule, " (H)# = HH2", seems to have a chance. Section B certainly matches. Section A also matches by default because there is no criteria to be met—anything may be in front of the H for this rule to pass. Section C has a # in it which means that one or more vowels must follow the H in HOW in order for the section to pass. This it certainly does because there is one O following the H. The rule passes, and the address and priority of the rule (2) are held for future reference. Remember that the priority given to a rule is the total number of symbols in sections A, B, and C.

And now the next rule, "(HOW) = HH2AW ", is loaded for testing. Section B has H, O, and W in it which perfectly matches the three characters starting with H in HOW. Section A has no criteria and therefore passes as does section C. This rule passes and the priority (3) is compared to the current highest (2). Since it is higher, the address for this rule and its priority replace the previous maximums.

The final rule, "(H) = PA1", also passes, but its priority is less than the current maximum of 3 so it is ignored. When the zeros are read in, that indicates the end of the rule group has been reached.

With all of the rules in the H group having been tested, the rule chosen for translation is the "(HOW) = HH2AW " rule. Therefore, those two allophones are converted into their respective hexadecimal codes and added to those (if any) in the buffer which holds the codes to be sent to the synthesizer. Notice that all of the allophone names (HH2, AW) have exactly 3 characters in them. This makes it easier for the Translator program to find and convert them into their hexadecimal codes.

The next thing is to advance the pointer (which points to the character which is being tested) to the next testable character. In this case, it skips over the O and the W because their pronunciations were included in the translation of the H, since they were all in section B. The pointer would therefore move to the next character past the W. But since there are none, the translation is complete and the allophone codes are sent to the synthesizer. (If the word had been HOWDY, the rule group for D would have been located and the process repeated for all the rules in that group, and then the Y group, if necessary.)

Final Comments

This project took me considerably more time and effort to produce than did the first Cheap-Talker project, but the rewards were greater. It is fascinating to be able to allow any program to generate understandable speech without having to maintain a high overhead in terms of memory. I think this project is more usable in diverse applications than the dictionary version described in my first article.

As I stated before, there are many ways to improve this project, but I hope I have been able to give ideas which will kindle the experimenter's spirit in you. Please drop me a note and let me know what you're up to, and if I can answer any questions not covered here (I'm sure there are some), let me know.

The programs described in this article are not listed here, of course, since the combined lengths of the algorithm and rules were pushing 8K bytes of memory. That's about 2200 lines of assembly listing, or 70 pages, which is a little too long to publish in a magazine article! If you wish to have the source code for everything described here, I will send it by mail for $25.00 ($26.50 for Californians, $30.00 for those outside of the US).

I will send you a DOS 3.3 disk which will include (1) object code for the driver and translator programs and the rules for use with systems with or without a 16K card (the disk automatically loads the appropriate code); (2) source code for the above software in LISA assembler format; (3) source text for the same in DOS 3.3 text files for conversion to other assemblers; (4) a small artificial intelligence/speech synthesis demonstration program in Basic, and (5) a small Basic program for testing the pronunciation capabilities of the translator.

If you do not own an Apple computer and would like just a source listing of the programs on paper, I can send that to you for $15.00 ($15.90 for Californians, $20.00 for those out of the country).

I hope this project will provide some useful ideas and enjoyment for you. Keep talkin'!■

Try an Inverted-Psi Wire

Get the DX edge on 80m with a radiation angle that's almost too low!

Capacitance hats have always appealed to me, especially with vertical antennas. I don't think we take enough advantage of these devices and this is particularly true at the lower-frequency bands such as 1.8 MHz and 3.5 MHz.

Some commercially-manufactured vertical antennas have capacitance hats, usually with a radius of less than 1 foot. This is much too small to have any effect except perhaps at 21 and 28 MHz. A capacitance hat can actually be quite large without producing any detrimental effect on the performance of an antenna; a 0.1-wavelength radius is quite practical.

This article describes the theory of operation of an antenna that I call the "inverted psi" because of its physical shape. The antenna uses a loading inductor and a large capacitance hat to provide low-angle radiation for DX on (in this case) the 80-meter band. The antenna is just 16 feet high, but it performs almost as well as a full-sized quarter-wavelength vertical.

Capacitive Loading

A capacitance hat at the end of any antenna will reduce the impedance at the end, raising it at the center. The larger the capacitance hat, the more pronounced this effect will be. If the capacitance hat is made too large, the current in the radiating portion of the antenna will drop too much and the low-angle radiation (in the case of a vertical antenna) will be impaired. But this does not happen to any significant extent until the radius of the capacitance hat exceeds 0.1 electrical wavelengths. At 3.5 MHz, this radius is more than 26 feet!

In general, the maximum allowable radius of a capacitance hat, designated by r and denoted in feet, is equal to 93.6/f, where f is the frequency in megahertz. Table 1 shows the maximum allowable radius of a capacitance hat for various amateur bands from 1.8 through 29.7 MHz, assuming we can get away with 0.1 wavelengths.

You will notice, no doubt, that no commercially-made antennas have capacitance hats this large.

Why use a capacitance hat with a vertical antenna? Because it greatly increases the effective height and improves the performance accordingly. This is not just theoretical speculation; it is a practical, useful fact. The performance of the inverted psi justifies this statement.

Because of geographical limitations I was able to use only two wires as the capacitance hat for my 80-meter vertical antenna. Ideally I would have employed four radial elements, but the antenna had to be put along the edge of a dock to take advantage of a salt-water ground plane. (If I had put any wires out into the water and the authorities had noticed, there would have been serious repercussions.)

Fig. 1 is a schematic illustration of the 80-meter inverted psi that I constructed. The vertical element is a little less than 16 feet high. The two capacitance-hat wires are about 22 feet long; this makes the antenna resonant at about 3.600 MHz.

The antenna is also resonant as a quarter-wave radiator at 14 MHz. The height of the vertical radiator was not chosen by accident. I like both 20 and 80 meters.

Antennas of this type can also be designed for 40 or 160 meters. Some years ago

Frequency (MHz)	Radius (Feet)
1.8 (band edge)	52.0
2.0 (band edge)	46.8
3.5 (band edge)	26.7
4.0 (band edge)	23.4

Table 1. Maximum capacitance-hat radius for antennas according frequency, assuming 0.1 wavelengths as the largest tolerable.

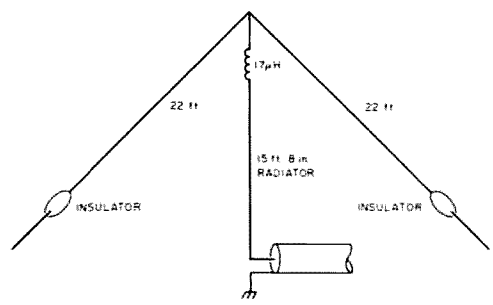

Fig. 1. Schematic illustration of the inverted-psi design for 80 meters.

I built a 10-foot version of this antenna for 40 meters and it worked very well, even with a marginal ground system. (I do not have the real estate to put up a 160-meter inverted psi—yet.)

Ideally, a capacitance hat would take the form of a solid metal disk at the top of a vertical radiator (Fig. 2). If the height of the vertical radiator is h feet and radius of the disk is r feet, then the effective height, h*, in feet, is approximately h + 2r.

That is the ideal case. The inverted psi is a little less than ideal, but the two 22-foot top-hat wires obviously increase the effective height by at least 22 feet. More probably (I didn't have an impedance bridge to precisely figure it out), the effective height is increased by about 1.5 × 22, or 33 feet. Along with the 16-foot radiator, that would result in an effective height of 16 + 33, or 49 feet. Almost a full-size quarter-wave vertical antenna!

The above is a little bit speculative. The real test of an antenna is not done on paper, but by putting it on the air and seeing how it works.

I built the antenna in a couple of hours one evening, had supper, fell asleep, woke up at 6:00 in the morning, turned on my receiver, and heard a ZL on 3.507 MHz. Promising.

Photo A. Top coil assembly for the inverted psi.

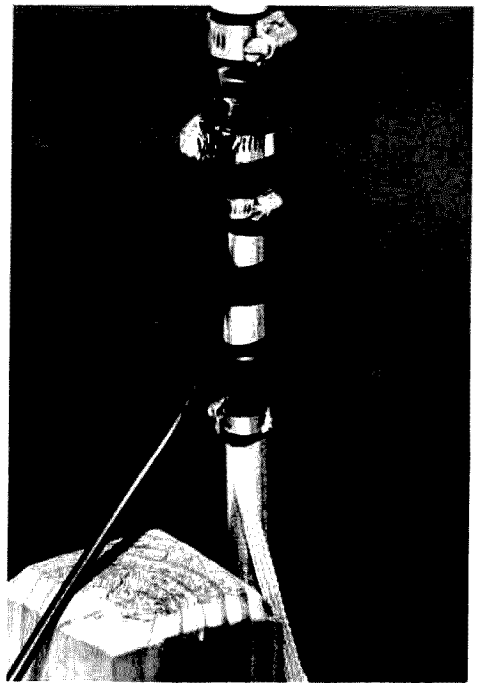

Photo B. This is the base assembly used at W1CV/4.

Grounding

A good ground system is essential for the performance of any ¼-wave antenna. An extensive radial system should be used. Ideally, this would consist of a metal plate having a radius of at least an electrical quarter wavelength and either buried just beneath or laid on top of the ground. I was fortunate enough to live in a place where this kind of "super ground" was almost provided to me by nature: I was staying in an oceanfront home. Salt water has conductivity many times that of even the best earth.

I used two 30-foot lengths of tinned ground braid immersed in the salt water and running outward from the antenna base in opposite directions (Fig. 3). The tinned braid would not corrode as quickly as plain copper, I figured. This proved to be true. The braid was about 1 cm in width, and this provided good contact with the salt water. A massive radial system was not used and, as it turned out, the antenna worked very well simply because of the salt water. If you don't have access to a salt-water ground, however, I would recommend that you install as many radials as possible, making them all as long as possible.

Construction of the Top Loading Apparatus

I used a loading coil at the top of the antenna in conjunction with the two 22-foot capacitance-hat wires. It occurred to me that I could use a toroidal loading coil. I obtained a Palomar Engineers T-200-2 powdered-iron toroid core and wound 38 turns of heavy, insulated wire on it, obtaining an inductance of 17 uH. (This value was determined by experiment, but I will spare you the details of the painful story: "Put it up, take it down, cut a few turns off, put it up, take it down. . .")

Being sure that the toroi-

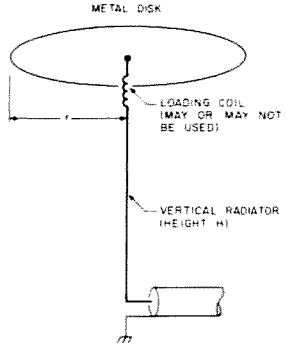

Fig. 2. Ideally, a capacitance hat would take the form of a solid metal disk at the top of a quarter-wave radiator.

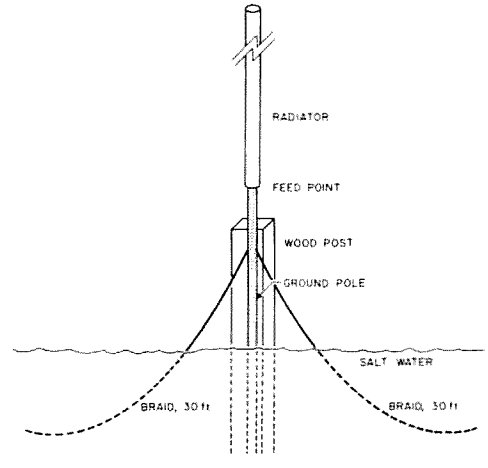

Fig. 3. Grounding scheme used at W1CV/4. The salt water proved to be an excellent ground plane.

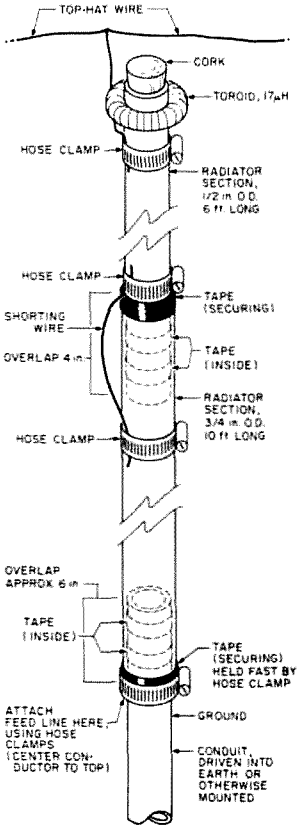

Fig. 4. Diagram of antenna construction, including base assembly. The center conductor of the feedline is connected to the bottom of the 10' section of ¾" conduit. The coax braid is connected to the top of the lower ½"-o.d. section.

dal coil was large enough to fit around the vertical radiator section (which was ½" o.d.), I placed it there and secured it with electrical tape (Photo A). The two 22-foot capacitance-hat wires, made from uninsulated AWG no. 22 tinned copper wire, were soldered to one end of the coil. The other end was wrapped with electrical tape and secured to the vertical radiator with a hose clamp.

It is important that the coil be kept in place and prevented from sliding down the radiating element. The hose clamp would be adequate for this (see Photo A), but I put a little extra tape around the vertical radiator for good measure. (You will notice from the photo that I also wrapped the toroidal inductor with tape. This isn't really necessary. I guess I have a certain fondness for black plastic tape.)

Frequency (MHz)	Swr
3.500	2.0
3.525	1.8
3.550	1.7
3.575	1.5
3.600	1.4
3.625	1.4
3.650	1.5
3.675	1.6
3.700	1.9
3.725	2.1
3.750	2.3

Table 2. Measured swr values for the 80-meter inverted psi at W1GV/4. Center frequency was approximately 3.600 MHz.

The toroidal inductor might not handle the maximum legal power limit. I don't know how much power it will take, although I am reasonably sure it will work with several hundred Watts. I tested this antenna (and used it for general operation) with only 20 Watts of rf output. Another of my loves is QRP. (Do I hear someone saying 20 Watts is *QRO*?)

Construction

The parts list shows what was needed for the construction of the inverted psi for 20 and 80 meters at W1GV/4. I won't go into a lot of detail regarding the construction since you can probably figure out how to put up a 16-foot vertical. The important consideration is the base mount: It must provide good insulation along with mechanical strength.

I did not happen to have a ready-made base mount, so I was forced to construct a home-brew one. The lower section of steel conduit, measuring ¾ of an inch in diameter, was slipped over a ½-inch section of conduit which had been wrapped with some plastic tape to provide insulation as well as a tight fit. The ½-inch section of tubing was attached to one of the posts of the dock and rested on the bottom of the canal in front of the house. Photo B shows the base mount including the coaxial feedline.

Fig. 4 shows schematically how the base mount was put together. The conduit could be driven into the ground, attached to a fence post, or anchored down in any other reasonable way. The main consideration is that the base of the antenna be reasonably close to the ground—within a few feet, at most, of the radial system or other ground plane.

Mechanical strength is also important with the base mount. I used steel conduit (not aluminum tubing) for this antenna because I couldn't find any aluminum tubing at local hardware stores. This proved to be a good thing, however, since the Florida Keys can get quite windy (55 knots is not unusual) and I was not able to guy this antenna because of its location. The antenna withstood 55-knot winds without incident. For extra strength, you might want to guy the antenna from the top with two pieces of twine or nylon cord in addition to the two top-hat wires. A well-guyed antenna of this kind would probably withstand hurricane-force winds, unless struck by a falling tree branch or other windblown object.

Base-mount capacitance is not especially important since the feedpoint impedance of this antenna is relatively low. Several inches of overlap can be tolerated. It is important only that water be kept out of the antenna. This is ensured by plugging up the top of the vertical element with a cork, rubber stopper, plastic tape, or some other waterproof substance.

Tuning

This antenna will not function over the entire 80m band since it is an inductively-loaded antenna and is physically shortened. Besides, the 80-meter band is, in terms of percentage, the widest of our high-frequency bands, and even a full-sized antenna won't display a low standing-wave ratio (swr) over the whole range of frequencies.

The inverted psi, given a good ground plane, should have a 2:1 swr bandwidth of 150 to 250 kHz. Table 2 shows measured swr values at W1GV/4, using RG-58/U coaxial-cable (52-Ohm) feedline. The center frequency was chosen by trimming the two top-hat wires a few inches at a time. Naturally, I started out by trimming off way too much wire and had to splice some back on (Murphy 344:24-26). *Note*: It is not imperative that the two top-hat wires be exactly the same length. A small difference will not have any effect on antenna performance.

The top-hat wires can be brought down at any angle greater than about 45 degrees with respect to the vertical radiator. At W1GV/4, the angle was about 60 degrees. You can run them out horizontally if you wish, but don't bring them down at any angle sharper than that at which the ends of the top-hat wires nearly touch the ground—that's about 45 degrees—and do not electrically connect the ends of the wires to anything metallic! The swr curve as well as the center frequency of the antenna will depend to some extent on the angle at which the wires are brought down. The bandwidth will also be affected somewhat: The larger the angle (the more nearly horizontal the wires), the greater the bandwidth.

The information in Table 2 was obtained at W1GV/4 with an intended center frequency of 3.600 MHz, roughly in the middle of the CW/RTTY/AMTOR band.

Don't expect your swr curve to be *identical* with that in the table even if you happen to choose the same center frequency. But if you get results that are *dramatically* different, say, a minimum swr of 4:1 or a bandwidth of only 20 kHz, then something is wrong and you should recheck your installation.

Performance

After the tuning and swr-checking phase, it was finally time to start operating with the inverted psi. As I said, I did some casual listening at first and heard a ZL near the bottom of the band. I hadn't ever heard a ZL on 80 meters before, although I must confess I hadn't ever tried that hard for DX on this band. I tried to call him with my 20-Watt output, but to my dismay I noticed that I had neglected to plug my keyboard into the transmitter (Murphy 345:7-8). By the time I had yanked the transmitter off the shelf and plugged the keyboard in, the ZL was gone (Murphy 345:9). But other opportunities would come up.

Several fairly distant stations were worked with good reports. A VE1 gave me a 589; he was in a direction almost opposite the salt-water ground plane. Numerous stateside and VE stations were contacted with ease, and they gave me reports that, in most cases, were as good as or better than those I gave them. (I admit to being stingy: "Good signals" are, I think, S6, right?)

I did not run more than 20 Watts of rf output at any time while using this antenna. For one thing, I had modified my transmitter so that I couldn't even if I was tempted; secondly, as I've said, I like QRP. And there is another thing. I have a terrible fear of potential TVI/RFI victims who swear a lot and who own guns.

The antenna worked quite well on 20 meters, not to my surprise since it is a full-sized quarter-wave radiator there. If you plan to use this antenna on 14 MHz, you should put the base mount as close to the ground plane as you can manage. In my case, it was 3 to 5 feet above the level of the salt water (depending on the tide), and hence the swr was rather high—the resonant frequency being below the bottom of the band and, moreover, the swr varied as the tide went in and out. Still, worldwide DX was no problem. The antenna would no doubt have worked even better at 14 MHz if I had made it a little shorter to compensate for the elevation of the base. ■

Parts List

2	Steel conduit or aluminum tubing, ½" o.d., 10 ft. long*
1	Steel conduit or aluminum tubing, ¾" o.d., 10 ft. long
1	Toroid core, powdered-iron, Palomar Engineers T-200-2 or equivalent, wound for 17-uH inductance
2	22-foot lengths of wire, type not critical, AWG no. 22 to 18
2	Insulators for ends of top-hat wires
10	Hose clamps (you can never have too many of these), 1" diameter.
1	Roll of electrical tape
1	Base-mount apparatus, constructed to your own taste
1	Cork for top of antenna
1	Length of coaxial cable, 50-Ohm preferred
1	Roll of strong twine or nylon cord for securing top-hat wires
1	Long roll of wire for radial system (if ground mount used)
1	Ground rod (if earth ground used)
1	Roll of heavy ground braid (if salt-water ground used)
1	Standard tool kit

*One of which is cut to 6-foot length

Selcal and State Machines

WA7NBF takes the mystery out of this powerful technique with a hands-on selective-calling project.

Neil A. Robin WA7NBF
21 Canter Lane
Sherwood OR 97140

The majority of hams have been exposed to the popular VHF/UHF FM equipment on the market today. If you've purchased any, you'll more than likely choose to have the touchtone™ pad as part of the equipment. Most of us think of the pad as an important part of the two-meter environment because of the frequent availability of autopatch.

However, there are many other uses for the touchtone pad. One that has been of great interest to me is what is commonly referred to as Selcal (selective calling). We have several repeaters in Oregon (which are on high mountains) with wide coverage and high traffic. I frequently like to listen to these repeaters for calls coming my way, but don't like all the chatter hour after hour. Selcal will give me the quiet I want without missing calls.

Here's how it works: The receiving station has its audio output interrupted by a circuit which must sense a unique sequence of touchtones sent from the transmitter before it reconnects the audio to the loudspeaker. Whoever is calling at the transmitter must send this code before making a voice call. The specific circuit that senses these tones is called a dual-tone multiple-frequency decoder (DTMF). ("DTMF" is the more technical definition of the touchtone signals.)

The integrated circuits that do this task are very popular in the telephony business; they are the same circuits used to sense the dialing of your modern telephone. DTMF was cleverly designed so that it minimizes the chance of voice operation "tripping" the circuit. It works on the principle of sending two very precise audio tones over the circuit at the same time. The specifications of these tones are held to tight tolerances.

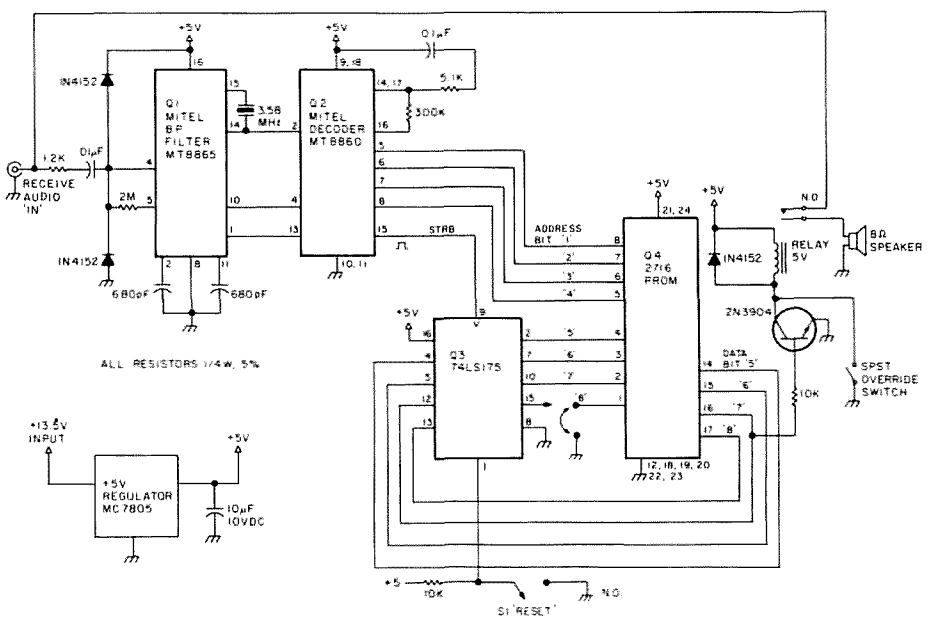

Fig. 1. Selcal schematic.

If you wish to monitor a frequency, then you need to place a decoder on the speaker output of your VHF/UHF rig along with a sequence decoder that detects the proper (secret) keying sequence. An outboard speaker is then wired so that only when the correct sequence is received does it get connected to the receiver audio. All stations calling for you must use the previously-defined sequence to enable your equipment and turn on the speaker.

Once you are done with the contact, you place the decoder in service again and the speaker is disconnected so that you remove all further audio. It's a great way to make life a little easier when you must monitor a repeater. It's great for husband and wife teams (my XYL is a ham), as you can keep in touch throughout the day. It can also be handy for emergency service teams. You can use the Selcal concept to call all the members in time of need using one common Selcal code sequence.

Another frequent use of the touchtone pad is for power-controlling purposes. You may use a sequence of DTMF tones to control any number of electrical devices in your ham shack or elsewhere. We truly have a very powerful tool on the front of our VHF/UHF hand-helds and mobile rigs. The controlling capability is already built into the rig; all we have to do is put it to use. If you let your imagination run wild, it's amazing what you can dream up as possible applications, but in order to keep this article short I will concentrate only on the implementation of Selcal.

DTMF Decoder

The first thing needed in implementing a system is a method of decoding the DTMF signals at the receiver audio. That is relatively easy today. We have modern VLSI integrated circuits which will do the job superbly. Several vendors have them on the market. The one used here is a set of two chips, Mitel MT8865 and MT8860. The first is a DTMF filter and the second is the actual decoder. Mitel informs me that this chip pair now sells for $28.00 in single-unit quantities. They also have a single-chip version.

DTMF Character	Binary Output
D	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001
0	1010
*	1011
#	1100
A	1101
B	1110
C	1111

Table 1. Logic of simple state machine.

The schematic of how they are connected is shown in Fig. 1. The output of Q2 is a simple 4-bit binary data word plus a strobe pulse. The strobe, pin 15, tells the remaining circuitry that it has received a valid DTMF signal and it has lasted long enough to ensure that it is not just random noise. You will notice in Table 1 the binary code that represents each of the unique DTMF codes. This particular chip set decodes all 16 of the tones. Many ham rigs have provision for sending only 12 codes; they leave off the codes for A, B, C, and D. As a result of these chips, we have converted the tones received into a 4-bit binary number. Not very complicated, is it?

Selcal Security

To make a Selcal system secure, it is a good idea to have a long sequence of characters to enable your system. I use a series of four which gives a unique pattern that would occur randomly only once in 65,536 tries. If someone wanted to find out what code I'm using, it would be easier for them to buy a chip set and decode it off the air directly. Also, by having several characters to enable the system, the probability of false triggering through voice patterns or noise is greatly reduced.

In the example, I use an enable sequence of 2-5-8-0 and a disable sequence of 5-6-6. The normal method of decoding a sequence is to use combinational or conventional logic. This usually takes the form of a digital comparator, a shift register, and a matrix of switches to set the code required for matching. This requires a fair amount of circuitry, particularly when you have to decode seven characters as mentioned above. An elegant method of doing this is called a "state machine" and offers some interesting advantages. First, the state machine is implemented with only two off-the-shelf low-cost integrated circuits. Many sequences can be decoded—far more than described here—with no additional circuitry.

GOAL

IF—
Input 1 goes high (logic 1) first and it is followed by input 2 going high while 1 remains high,
THEN—
Enable output high for one clock cycle

Address	Data Out	
0000	00	State 1 (reset state)
0001	01	
0010	00	
0011	00	
0100	00	State 2
0101	00	
0110	00	
0111	10	
1000	00	State 3
1001	00	
1010	00	
1011	00	

Table 2. Mitel MT8860 decoder output.

State Machine

The idea behind the state machine needs a little study for those who have worked only with combinational logic. First, most state machines are implemented with just two components: a PROM (Programmable Read Only Memory) and a set of type-D flip-flops. They work on the principle of establishing well-defined states for the logic. The states will progress from one to the next based upon the program that has been burned into

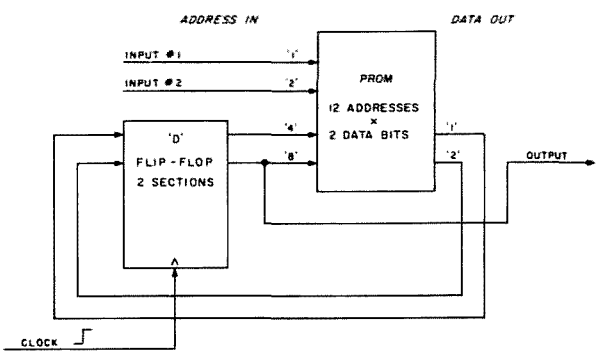

Fig. 2. The simple "state machine."

the PROM, the clocking signal, and the state of the input signals. The idea is well known to people who design microprocessors or other fast sequential logic but is unknown to most electronics experimenters.

To explain how a simple state machine works, let's refer to Fig. 2 and Table 2. First, assume that we have the design task of implementing the logic statement (goal) outlined in the table. Notice that this is not a simple AND gate; it demands that the sequence of input 1 precede 2 by an undetermined amount. Also, be aware that this logic is clocked rather than dc in nature. For anything to happen, the clock pulse must occur.

From this point on, it is important to abandon the idea that the clock must be a periodic signal. Rather, it will be the signal from our DTMF decoder that tells us that a valid code has been received. This is an important characteristic that makes a state machine a good way of implementing a Selcal circuit. The state machine advances only after we press a touchtone key at the transmitter. From a timing point of view, it will be random.

Now assume that we have programmed our 12-address-by-2-bit PROM with the code shown in the Table 2 truth table. The reason for this particular code will become obvious shortly. We will start with the output of the two type-D flip-flops in the logic 0 state. Notice that the output of the flip-flops drives the two most-significant bits of the address to the PROM. Therefore, the only possible addresses that the PROM could take would be between 0000-0011 binary, or what is shown as state 1 in the table.

The lower most-significant bits of the PROM address are tied to inputs 1 and 2. Hence, the state of the input signals controls, in part,

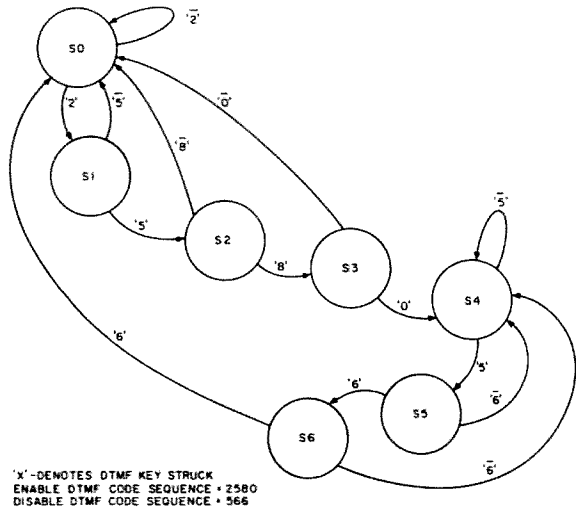

Fig. 3. Selcal state program.

the PROM address. If the states of the inputs are both low, the effective address of the PROM will be 0000. Now notice that the data word out of the PROM for that address is 00. In addition, the output of the PROM is also fed back to the input of the D flip-flops so that when a positive transition of the clock pulse occurs, the two most-significant bits of the PROM address will be updated.

In the example so far, they will be updated to 00 since that was the output of the PROM just before the clock pulse. The effective address of the PROM remains 0000. We also can say that the device remains in state 1. Now let's change input 1 to logic 1. The effective address is now 0001, but notice that the data word is now 01. If a clock pulse occurs at this time, the new effective address will become 0101 and we will jump into state 2 on the diagram.

Next, let's assume that input 2 goes high. The effective address becomes 0111. The data word is 10. If a clock pulse now occurs, we will jump to state 3. While the device is in state 3, the most-significant bit of the address is set high. We can use this bit as an output to solve our logic equation. Notice that it remains high until the next clock, which then will drive the circuit back to state 1 in all cases since the data word is 00 for every condition of the input lines. The next effective address must be somewhere in state 1.

Now we'll go back to state 2 and see what would happen if input 2 didn't go high during this state. The effective address would be 0101 and the data word would be 00. The next clock pulse would load the flip-flops with 00 which would, of course, drive the most-significant address bits back to the state 1 condition. We see that the logic was not satisfied and the output was never driven to state 3. It should now be clear that to get an output-high condition, the proper sequence of events in this particular goal statement must be satisfied. If they are not, the logic forces you to keep jumping back to the reset state—state 1.

Many variations of these concepts exist. It is suggested that the reference at the end be used if you wish further information. One common difference that you find on most state machines is that the output usually is taken from the data word directly. In this example, it's easier to take it from the flip-flops. Most machines are based on this simple idea of a PROM and D flip-flops. The great advantage is the simplicity of the hardware and thus the very low cost.

Selcal or Bust

Now that we have the foundation of the concepts, let's put it to practical use. Suppose that we want to build a Selcal circuit that will activate our receiver speaker whenever the DTMF sequence of 2-5-8-0 is received and will disable it when 5-6-6 is received. We will use a 2716 PROM (UV erasable) which can be purchased for $2.95, plus a 74LS175 quad-D flip-flop which is about $0.75. See Fig. 1. The PROM is very popular with the computer hobbyist and has a configuration of 2048 addresses by 8 bits. We will use it as if it really were only 128 addresses by 4 bits. We have far more capability in this device than we need, but on the other hand it's cheap and we may want to expand our circuit with more exotic capabilities at a later date. A great place for experimentation.

The state machine is driven by the Mitel MT8860—Q2 in Fig. 1. The output of this chip follows the truth table in Table 1. These four bits will be used as the four least-significant address bits of the PROM. The next three most-significant bits will be derived from the output of the D flip-flops (3 each). The inputs to the flip-flops result from bits 5, 6, and 7 out of the PROM data word. Bit 8 is also routed to one of the flip-flops in Q3 but is used for future expansion only. Data output bits 1-4 will not be used and are not shown. (They could be used as outputs if desired.)

Earlier, I mentioned that the clock to a state machine may be from a random event. Here we'll derive the clock from the strobe command out of Q2. This signal goes high when a valid DTMF tone has been de-

tected, so it may be somewhat random. The relay to connect the loudspeaker is driven off bit 7 of the data word. The entire circuit including the DTMF decoder requires only four integrated circuits.

The first step in programming the PROM is to introduce the concept of the "state diagram." This is shown in Fig. 3. It is much like a flowchart, but we specifically refer to each condition as a "state" or address subsection in the PROM. It is an excellent diagram to show what happens when an invalid code is received.

State 0 (S0) is the reset state. The only way to advance to state 1 (S1) is to receive a 2 in the DTMF code. Once in state 1, you must receive a DTMF 5 code to advance to state 2, etc. Notice what happens if you are in state 1 and something other than DTMF 5 is received: You resort back to state 0. By studying this diagram, you will see that the only code sequence that will allow you to advance to state 4 will be 2-5-8-0.

State 4 is the address range, $40-4F (a $ ahead of a number means it is in hexadecimal). Bit 7 is used as an output, hence the speaker is turned on. In fact, it will remain on until the 5-6 sequence occurs, and will be unconditionally off after the 5-6-6 sequence and the state diagram shows a return to state 0. The PROM program is shown in the PROM program listing. To change to some other sequence you need only change the program.

The listing is shown in hexadecimal. The PROM was programmed using an assembler on the Apple II computer. With only 128 addresses needed, it could be done manually. The computer is handy, as it makes the programming very simple. If you don't have a PROM burner in your ham shack, locate a fellow ham who is into both ham radio and computers. More than likely it won't take long to find someone who can help. Also try the local computer club.

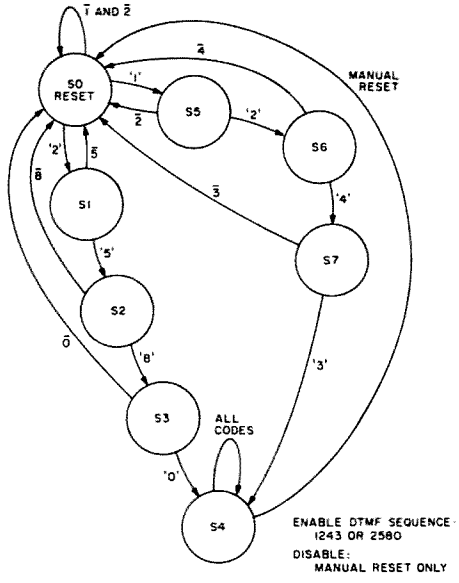

Fig. 4. Dual-sequence Selcal.

The actual hexadecimal addresses are located on the left-hand side of the listing. Notice the state labels, S0, S1, S2, etc., after the line numbers. They point to the beginning of the address group that represents that particular state. Since IC Q2 determines the lowest 4 bits of the effective PROM address, each state will have a total of 16 possible addresses. One of the data words in each group of 16 will point to the beginning of the next state if that particular effective address is chosen.

For example, assume you are resting in state 1, and Q2 sends a 0001 to the PROM. This is the equivalent to a DTMF 1 from Table 1. The effective address will now be $11. This is true because Q3 must be statically holding a $01 (to force it to state 1) plus the 0001 code from Q2. Location $11 produces, from the listing, a data word of $00. When the next clock pulse occurs from pin 15 of Q2 (which means a valid DTMF tone is received), a $00 will be loaded into Q3 and the PROM address range will return to the state 0 address range.

Now let's go back again and assume we are currently resting in state 1 and this time a DTMF 5 occurs. This puts 0101 into the lower 4 bits of the PROM and makes the effective address $15. Now, at the time of pin 15 strobe, the data word of $20 will be presented to Q3 and the machine will go into state 2. We are hence progressing down the state diagram in Fig. 3 to solve for the unique combination of 2-5-8-0.

You will notice that once you get to state 4, bit 7 of the data word will be high. With bit 7 connected to the base resistor of the 2N3904, the relay will be enabled. This relay controls the speaker. The relay will remain enabled until the unit is either manually reset by pressing push-button S1 or by sending the reset code which will cause the machine to progress to S5, S6, and a return to S0.

A word about state 7 is needed. You'll notice on the state diagram that we never call the state 7—so why was it coded into the PROM? The PROM is hard-wired so that addressing bits 9, 10, and 11 are held at logic 0. That restricts the possible addressing range to the lowest 128 addresses, which is $7F in hexadecimal. When power is applied, we want to be sure that the machine comes up in a recoverable state. S7 is a possible power-up state since it is in the possible address range. When in S7, Q3 will force the PROM into S0 the next time a signal comes from pin 15 of Q2. Likewise all other states can be shown to be recoverable.

Another way would be to cause a reset to Q3 upon power-up. This would always guarantee that state 0 was reached, but without state 7 there is still the possibility of a lockup. The best solution is to use both. I didn't incorporate an auto-power-up reset in the circuit since it self-recovers if you have a power failure. The manual reset push-button, S1, is used for local reset in the event the caller did not send the reset sequence, 5-6-6.

Notice the jumper at pin 15 of Q3. In this example, the Q4 address bit 8 is grounded rather than being connected to pin 15. This restricts the address range as mentioned above to 128. When this jumper is connected to extend the addressing range to 256, it represents the latched 8th bit of the data word. It could be used for an additional control circuit. In addition, the lower 4 bits of the Q4 data word serve no purpose in this design, but could easily be used for additional control circuits. With Q3 being four bits wide, and Q2 supplying four bits, the maximum address range is 256.

The PROM has a capacity of 2048. To extend the useful range to its maximum capability, some additional storage registers are needed. This could be done by adding another 74LS175 or by feeding some of the data bits back into the addressing lines. That is beyond the scope of this introductory article.

PROM program listing

Construction

The crystal shown in the diagram for Q1 is a standard low-cost TV sub-carrier type. The ICs use different sockets: two with 16 pins, one with 18 pins, and one with 24 pins for the 2716. All of these parts should be easy to obtain by mail order or any store that caters to the computer hobbyist. The silicon diodes can be any general-purpose small-signal type, and the capacitors are not critical.

The relay was found in my junk box, but any type that is compatible with the power supply and the driver transistor will work. The actual circuitry uses only +5 volts. Since my receiver runs off +13.5 volts, I chose to power the unit with a packaged +5-volt regulator, the MC7805C. It costs about $0.95. The layout is noncritical, but some care should be taken to avoid static in handling the IC devices. It is recommended that a metal box be used for an enclosure since strong rf fields in the immediate vicinity can cause erratic operation. Use shielded audio input lines, and be sure that the power leads have rf bypassing.

Although this unit uses only four ICs, Mitel now has a single-chip DTMF decoder, the MT8870, which sells for about $20.00 and could reduce the count to three devices. I've not experimented with it. (The West Coast sales office can be reached at (408)-249-2111.)

Emergency Calling

An important additional feature that could be designed into the PROM program is a dual-access code. The first would be your own private sequence such as 2-5-8-0, and the second would be common to all your members, say 1-2-4-3. Fig. 4 shows the state diagram of this hypothetical example. Whenever a sequence of 1-2-4-3 is received, all members of your organization would have their Selcal circuit activated. Whenever the 2-5-8-0 is sent, you would be the only one to have your system enabled. This is a powerful way to organize an emergency services net, for example. Reset would occur manually.

Disadvantages

Although the state machine is very cheap to reproduce, it suffers when you change to a new coding sequence since you must burn a new PROM. I personally don't consider this a problem because I have equipment handy to do the job. Many people may not. At first you may think of it as complicated, but it just takes getting used to thinking in terms of state-machine implementations instead of conventional logic. You'll be happy later because of simpler circuits and greater reliability. The state machine is more familiar to computer types rather than old-time rf guys, but on the other hand, this may be a good way to learn.

Operation

A few things have been noted in the use of the circuit. First, it's always a good idea to start the DTMF sequence with some unused key. In the above example, this could be "#". The sequence then would be: #-2-5-8-0. The reason is that noise may have taken the state machine to state 1 or 2. Any non-valid key will drive the state back to 0. From that point on, you know the proper sequence to follow. This helps ensure that you start out in a reset state.

The second observation is that if you have reached state 4, you cannot get back

to state 0 without sending cancel code 5-6-6 or hitting the reset push-button. Here again, use an unused key first before you send the 5-6-6, e.g., #-5-6-6. This will force the machine back to state 4 before you send the correct sequence to reset the circuit.

If you intend to use this device through a repeater, be sure to get permission from the control operator. Give him your access code, out of courtesy. If he's aware of the code you're using he can tell you if you have selected any sequence that could cause problems with the repeater-control system. This is particularly true when using a random reset code. One that I always try to avoid is the "*". Many repeaters begin their autopatch operation with an asterisk.

I've checked with the FCC as to the acceptability of using the described concept and they see no problem. If you're considering using the DTMF tones for controlling electrical circuits, check with the amateur rules as to acceptance.

Another operational approach seems to be to leave the squelch open when the Selcal is enabled so that when you do hear the receiver hissing noise, even if you were out of the room, you know that someone has tried to call. When you attach the Selcal to your rig, the local built-in speaker should automatically be disconnected. All rigs I've seen work in this fashion so you shouldn't have any modifications to make to your radio equipment.

There are many variations to the above circuit. Let your imagination flow and let me know all the good ideas that result. Happy Selcalling! ■

NEW from BARKER & WILLIAMSON!

1.8 - 30 MHz. Continuous Coverage Antenna for Commercial and Amateur Service

Model AC 1.8 - 30

The AC 1.8 - 30 Antenna uses only 80 feet horizontally, and, when space is limited, can be shortened even further with only slight loss of radiation efficiency.

U.S. Patent 4,511,898

- SWR Maximum 2:1, 1.4:1 Average
- Handles 1 KW input ICAS
- Can be installed in approximately 80 feet of space
- Higher power models available (contact factory)

Little or No Resistance

Explore the strange world of superconduction, where current flows forever and a picosecond is an eternity.

A new electronic technology is emerging in many laboratories around the world. This new technology, superconducting electronics, is as different from semiconductors as the now vanishing technology of vacuum tubes. Superconducting electronics is made possible by a number of unusual conditions that may occur in electronic circuits when they are cooled to extremely low temperatures.

A number of metals and alloys lose all resistance to electric currents at temperatures a few degrees above absolute zero (−273° C). In a superconducting circuit, a current can be maintained almost indefinitely once started. Alternating currents may still experience some impedance at superconducting temperatures, but these impedances are very low compared to those that are encountered in conventional circuits.

Not only temperature, but magnetic fields and current density also determine a material's ability to become superconducting. As current densities increase, a material becomes more susceptible to the squelching of superconductivity which can be caused by a magnetic field. Increasing current densities and magnetic-field strength also reduces the temperature at which a certain material will become superconducting.

An extremely small particle may appear to have passed through a barrier without punching a hole in it. This phenomenon is called tunneling. For the electron, tunneling is possible provided that the barrier is less than a few hundred atomic diameters wide. A thin film of isolating material between two films of conducting material is a tunnel junction. At room temperatures, a tunnel junction may show a resistance of several hundred Ohms.

In 1962, an English scientist, Brian Josephson, predicted the behavior of a tunnel junction at extremely low temperatures. He believed that at superconducting temperatures, the tunnel junction itself would become superconducting. In this condition, no resistance or voltage could be measured across the junction. Brian Josephson predicted that a small magnetic field could turn the superconducting tunnel junction back to its resistive state. He also predicted that the superconducting tunnel junction would return to its resistive state if the current rose above a certain value, which he called the critical current.

The superconducting tunnel junction could thus be switched back and forth between its superconducting and resistive states by controlling the current through a small loop of conducting material near the tunnel junction. This control current would cause a magnetic field ex-

ceeding the value which the superconducting junction would tolerate whenever the junction was to return to its resistive state. This new electronic device was soon observed in the laboratory and was named the Josephson Junction, after its discoverer. In 1973, Brian Josephson, together with two other pioneers in superconducting electronics, Leo Isaki and Ivar Giaver, received a Nobel prize in physics.

The Josephson Junction has several remarkable properties which make it an attractive component in super-fast computers. A Josephson Junction can switch its state faster than any other electronic component. The fastest Josephson Junctions have been observed to have switching speeds around 10 picoseconds. This corresponds to a frequency of 100 gigahertz.

Very fast computers must also be very compact in order to reduce the time which is required for a signal to move from one part of the computer to another. Each component in a super fast computer develops heat that must be dissipated. There are limitations to the amount of heat that can be dissipated from a small space, so a super fast computer with too many components in a small space could literally melt itself. The power consumption of a Josephson Junction is only about one thousandth of that of comparable semiconductor devices. The amount of heat which would have to be dissipated from a super fast computer using Josephson Junctions is, therefore, much easier to manage than the heat from a comparable semiconductor computer. The extremely low impedance which is encountered in superconducting wires and transmission lines is also making this technology attractive for super fast computers.

The Josephson Junction can be used as a voltage-controlled oscillator. If a voltage is established across a Josephson Junction, an alternating current will appear. The frequency of this alternating current is voltage dependent. The maximum frequency of such oscillators is far into the microwave region. This effect will also work in reverse. If an alternating current is coupled across a Josephson Junction, a voltage will appear that is proportional to the frequency of the alternating current. The output of a Josephson-Junction vco is of very low amplitude and would need a great deal of amplification before it could be used in most analog applications.

The Josephson Junction is more sensitive to magnetic fields than any other device. This led to the first commercial application of the technology. Magnetometers using these junctions have been on the market for several years.

A Josephson Junction is a latching device. Once it has changed state, it will remain in that state until the current through the junction is interrupted. But in contrast to semiconductors, Josephson Junctions work equally well with currents of either polarity. By using an alternating current as power supply, the latching effect can be cancelled. Each time the ac crosses zero, the Josephson Junction returns to its original state. In a computer circuit using Josephson-Junction technology, the alternating current which supplies the power to the junctions can also serve as the clock of the computer.

A new superconducting electronic device was presented by its inventor, Dr. Sadeg M. Faris of IBM, in January of 1983. This device, which is similar to the transistor in semiconductor technology, is called a quiteron. The quiteron uses two tunnel junctions and consists of three thin films of conducting material which are separated by two even thinner barriers of insulating material. A small change in the current between two of the conducting films will result in a large change in the output voltage from the quiteron circuit. So far, quiteron amplifiers have shown a power gain of only 10, but the gain figure is expected to improve as these circuits become more refined. The quiteron is very fast, like the Josephson Junction, and is capable of processing signals into the gigahertz range. The power dissipation of a quiteron is very small compared with semiconductor amplifiers.

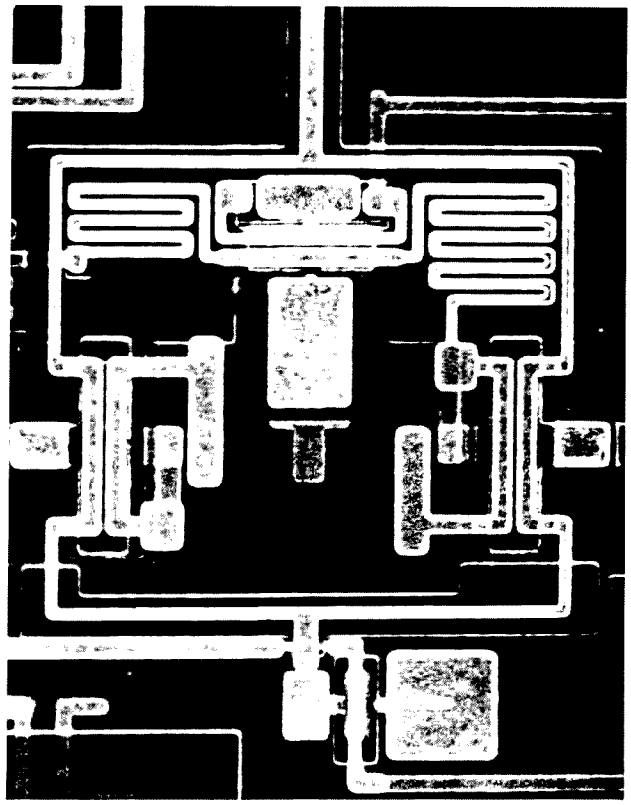

Photo B. This Josephson circuit is used in an oscilloscope system which is capable of measuring extremely fast signals. The Josephson Junction is the small circle in the center.

Superconducting technology is found also in circuits that have to pass very large currents. The strongest man-made magnets use superconducting coils. Extremely high current densities are possible in such coils (10^6 Amperes per square centimeter). The strongest superconducting magnets are capable of producing magnetic fields in excess of 8 Teslas, whereas the strongest conventional electromagnets are able to deliver only .3 Teslas.

Superconducting magnets are found in most laboratories that are attempting to develop fusion power. In order to generate power by fusing hydrogen atoms into heavier atoms, extremely high temperatures have to be attained. All solid walls would evaporate long before such temperatures could be

reached. But superconducting magnets may be able to generate magnetic fields that are so strong that these can act as substitutes for solid walls in fusion-power experiments.

An experimental levitated train system that has been developed in Japan uses superconducting magnets to lift the train. The train is, therefore, suspended in the air a few inches above the track. Due to the absence of mechanical friction, speeds of 320 mph have been reached in this levitated train system.

In the future, superconducting coils may be used for storage of electrical energy. Extremely high current densities are possible in such a storage system, and this may make it competitive with other power-storage systems. Once a current has been started in a superconducting storage coil, this can be sustained with very little loss for several days.

Modern electrical generators can be very efficient; up to 98 percent of the mechanical energy may be converted to electricity. But even higher efficiencies are possible by using superconducting magnets in the generators. Such generators may reach efficiencies of 99.5 percent. For large electrical generators, these savings may cause superconducting magnets to be competitive with conventional magnets, despite the higher construction costs. Superconducting magnets may also become cost-effective in large electrical motors.

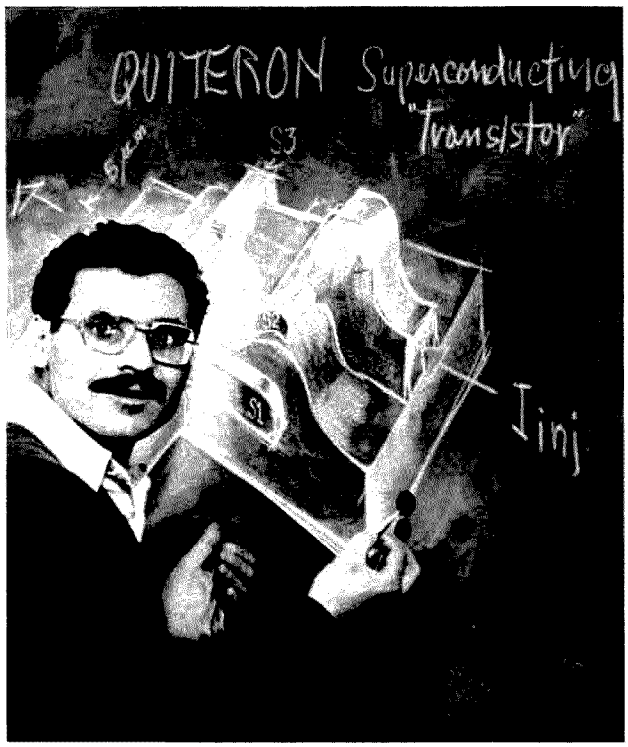

Photo C. The inventor of the quiteron, Sadeg M. Faris, and his new electronic device. The quiteron is a superconducting equivalent to the transistor, but works according to entirely different principles.

The main obstacle to a wide use of superconducting circuits is obviously the need to keep these circuits cooled to superconducting temperatures. Most refrigeration systems use liquid helium, which maintains the superconductors at a temperature of 4.2° Kelvin, the boiling point of helium. Helium is fairly expensive, and these refrigeration systems are not yet very reliable.

Many scientists believe that new superconducting materials will be developed which can become superconducting at higher temperatures than existing materials. A major milestone would be reached if one could discover a material which would turn into a superconductor at a temperature of 25° Kelvin or higher. This temperature is the boiling point of liquid hydrogen, and hydrogen-based refrigerators are likely to be much less expensive and more reliable than those that use helium as a refrigerant. The highest superconducting temperature which has yet been achieved is found in a niobium-germanium alloy. This alloy becomes superconducting at 23° Kelvin.

The Josephson Junction may be used as a very sensitive detector at microwave frequencies. Cooled parametric amplifiers have been used for EME work. Some years from now, superconducting components and refrigerators may become available from surplus stores and other sources. It is then possible that some new uses for superconducting electronics will be found in amateur-radio stations. ■

Run Silent, Run Beep

Is your FT-227RB scanning? You won't have to guess with this easy add-on.

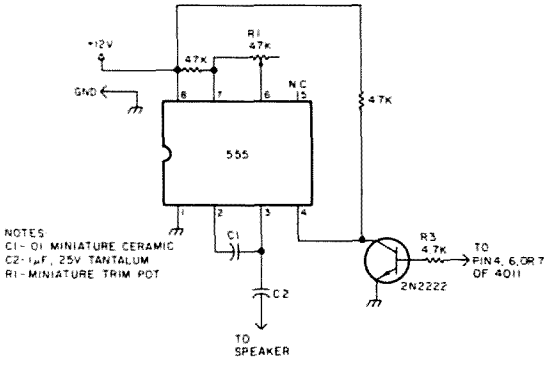

Fig. 1. Schematic.

If you are driving and are over forty (years old, not mph), you may have noticed how difficult it is to read a small digital display while in motion. In most cars the dial is not in the driver's line of sight, and in my case, I get tired of asking my wife if the display is scanning. It is dangerous when I am alone and have to take my eyes from the road to see the display. Also, sometimes a short noise stops the scanning, or the mike button doesn't start as it should.

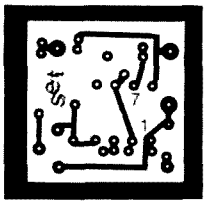

Fig. 2. PC board.

I know that the talking dial is coming, but in the meantime, for safety, I have equipped my Yaesu 227 RB with a beeper to assure me that it is scanning. This gadget will work with most transceivers. The beeper is like a birdcall or the sound of the synchronization operation on the Collins S-line (old-timers will recall this). The cost is around $4.00 for new parts or much less using your junk box. Look at the diagram: It is only a 555 integrated-circuit oscillator and a 2N2222 transistor inverter. I installed my unit in place of the optional tone squelch. If you have the squelch, install the beeper near the speaker in the bottom part of the transceiver.

In the 227 RB do the following: Open the top cover by removing the five Phillips screws. You will note a piece of gray cardboard fastened with three screws. Remove them, lift out the cardboard, and then raise the edge of the printed circuit nearest the dial only enough to

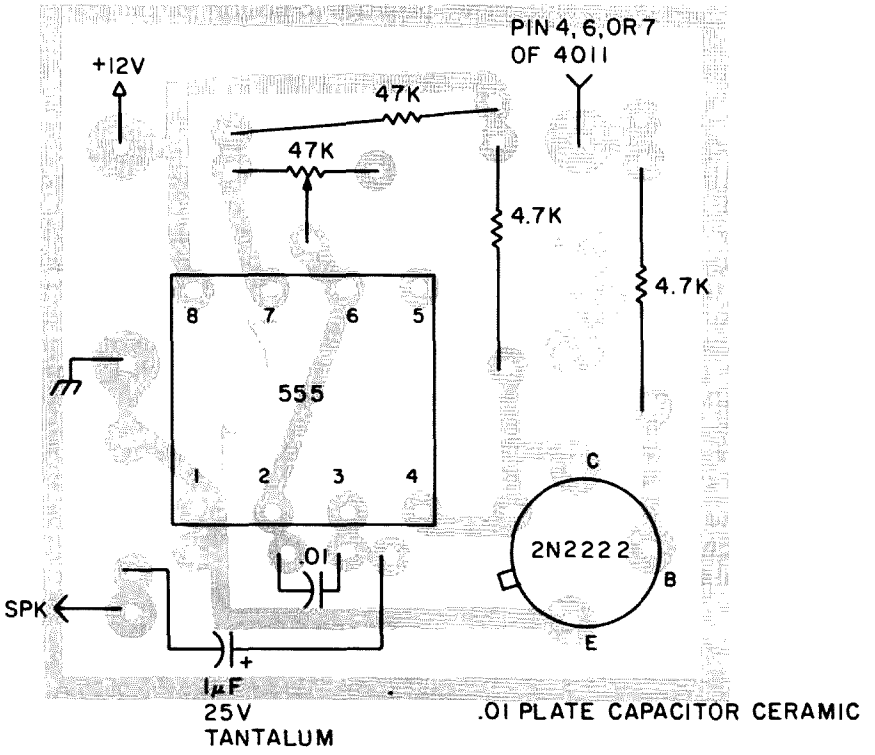

Fig. 3. Component layout.

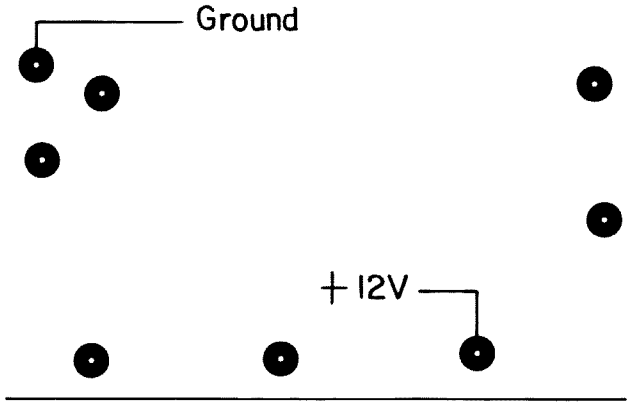

Fig. 4. Tone-squelch pin locations, seen from the dial side.

locate the MSM4011 integrated circuit. This IC is the scanning oscillator; it is in the center of the board and has 14 pins. Note that pins 4, 6, and 7 are tied together on the foil side.

At this point you should carefully solder a 4-inch piece of insulated wire if the beeper is to be located in place of the tone squelch, or a longer one to reach the speaker area if your beeper will be located there. The use of a small battery-powered or insulated iron is recommended as the IC is a CMOS.

Install the finished printed circuit by connecting the two wires (for the ground and the +12 V) to the pins indicated in the tone-squelch pin diagram (Fig. 4). The wire from the beeper that goes to the speaker is connected at the accessory jack, pin number 1. This pin is the one with a blue wire and a small ceramic condenser to the chassis. The last one is connected from pin 4, 6, or 7 of the MSM to R3 of the beeper. Fasten the circuit to the transceiver PC board with two drops of RTV. If you are locating it near the speaker, make the same connections with longer wires, routing them around any hot transistor. When the work is finished, connect the antenna and the 12 volts and try the scanning button. You should hear a low-volume beep when scanning. With the trimpot, adjust the tone to your taste. I am sure you will find this modification very helpful.■

We Give You VHF Without VHC.*

(* – Very High Cost)

Presenting Microwave Modules, the low-cost way to full-featured multimode operation on 50 Mhz, 144 Mhz and 432 Mhz.

Expand your HF transceiver's capabilities for less than the cost of a VHF multimode radio.

All models feature:
- 25 Watts RF output
- Low Noise GaAsFET front end
- Transmit ALC circuit
- RF sensed VOX T/R switching
- All-mode operation—SSB, CW, FM, AM
- Easy hook-up to your present HF transceiver

A Better Money-Maker

WA6TTY stiffens up his original power supply to deliver a solid 13.8 volts at 20 Amps. The cost? Under three bucks!

Kenneth D. Wyatt WA6TTY
Ehrhorn Technical Operations
PO Box 888
Canon City CO 81212

This article describes a simple method of improving the output regulation of the "Money-Maker Power Supply" (*73*, November, 1982).

I have been using the unmodified supply for the past four years with good results. At a full load of 20 Amps, however, the output voltage drops by up to one volt. Numerous readers have noted this anomaly. W4CNQ wrote and suggested using a Fairchild 78GU1C voltage regulator instead of the LM317. Although the 78GU1C is not as widely available, it does improve the regulation remarkably. The reason for this is its fourth "sense" lead.

The basic problem with the original power-supply circuit was the voltage drop across the base-emitter junction of the pass transistors (see Fig. 1). When biased into the active region, there is normally a base-to-emitter junction voltage of about 0.7 volts. As the collector currect increases, this voltage differential also increases. For power transistors it can be as much as 1.5 volts or so.

The original circuit applies a regulated voltage from the LM317 to the pass-transistor bases. At low current levels, the base-emitter drop is fairly constant; thus the output voltage stays fixed. As the output current increases, the voltage drop increases and causes the output to drop slightly.

The revised voltage-regulator circuit is shown in Fig. 2. The major difference is the addition of a voltage-sensing input to the regulator IC. This sense lead is connected directly to the positive output terminal of the supply. As the output voltage decreases with more load, the sense lead tells the regulator IC to boost the base voltage to the pass transistors. This feedback loop cancels out the voltage drop and the output voltage will stay nearly constant.

The 78GU1C may be purchased from Circuit Specialists, Inc., PO Box 3047, Scottsdale AZ 85257. The part costs $2.10, and $1.25 must be included for shipping (1983 catalog). Note that the part is mislabeled in their 1983 catalog as "78GI1C". The device is housed in a TO-220 package. The pin connections are shown in Fig. 3. The 78GKC may be used as an alternate part (TO-3 case). The price is $2.75.

Circuit Description

I used a 78GU1C as the voltage regulator. A 2N3055 was used to boost the drive

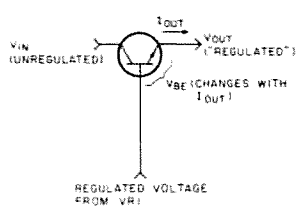

Fig. 1. Pass-transistor circuit. As the output current increases (Iout), the base-to-emitter voltage drop will increase (Vbe). This will cause the output voltage (Vout) to decrease slightly.

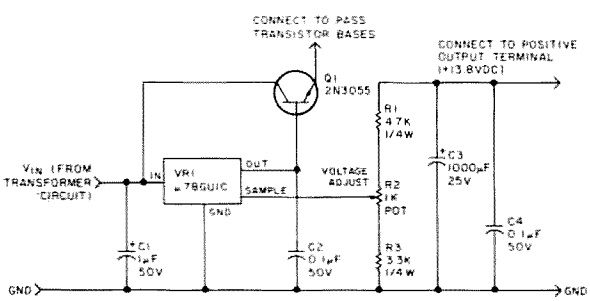

Fig. 2. New regulator circuit. The addition of a sample input on the voltage regulator creates a feedback loop which tends to keep the output voltage of the supply steady.

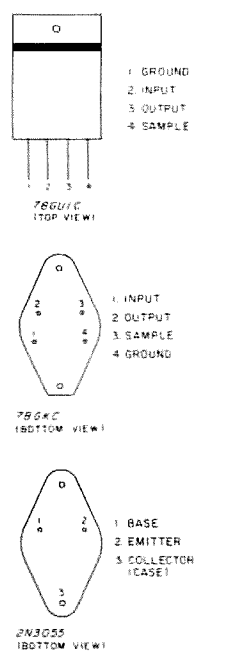

Fig. 3. Base diagrams. Note that the pin connections for the two voltage regulators are different.

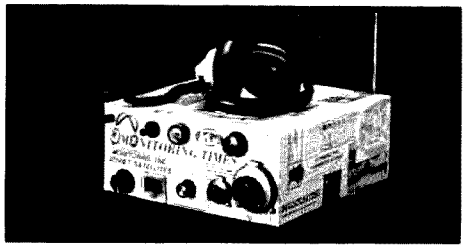
current to the pass-transistor bases. Two bypass capacitors (C1 and C2) are mounted as close as possible to VR1. They prevent rf from upsetting the regulator and also act to prevent the regulator from oscillating. Resistors R1, R2, and R3 form a voltage divider for the sample input to the regulator. For the values shown, the output voltage is adjustable from 10.8 to 14.0 volts dc. Capacitors C3 and C4 filter out any noise or rf from the sample input.

Once all the new components are collected, it is time for surgery. Remove the original voltage-regulator circuit from the power supply. This will consist of VR1, R1, R3, C3, and C4. Refer to Fig. 3 in the original article. R2, C3, and C4 may be reused in the new circuit.

Next, install the new VR1 and Q1 to the chassis. Isolate Q1 from the chassis using mica or plastic insulators. Don't forget to use a little silicone grease in the junction area. Finally, wire the remaining components in a point-to-point fashion using a terminal strip if required. Make sure that all four capacitors are mounted close to VR1.



Double-check all added wiring and remove any load from the supply. Adjust R2 for 13.8 V dc at the output terminals. Now reconnect your radio and you should be in business.

Conclusion

My supply stays in regulation out to 18 Amps. After that point it starts dropping down slightly. Your supply may differ a little due to transformer type or construction technique.

I guess the moral of the story is that it's OK to use LM317s for low-current applications, but use feedback techniques (78GU1C) for high-current applications. ■

Your Second Best Piece Of Monitoring Gear

Next to your receiver, a subscription to **Monitoring Times** is your most valuable tool for communications monitoring. This fact-filled monthly tabloid (hardware not included!) is written just for you, the listener, bringing you 36 pages of concise information on how to improve your listening post, where to look for those elusive signals, exciting home-brew projects—and more!

The Commodore Cable Caper

Need a printer cable? Strapped for cash? Don't just sit there—build the durn thing!

So you need a printer interface for your Commodore 64. Have you seen what they're asking for one? Well, between my junk box and the local parts house, I built one for a whole lot less than the $60.00 asking price on the one I saw.

The Commodore 64 already has an RS-232C interface built in. It's part of the user port. The only problem is that the voltage levels at the user port are TTL, and we need RS-232C levels.

Now hold on a minute. Just what are these levels I keep rambling about? And what is this RS-232C? First, the TTL levels are the voltage levels the computer talks to itself with. They are usually a +5 volts dc for a mark, or logic one, and 0 volts dc for a space, or logic zero. RS-232C is a little more complicated. Rather than discuss everything about RS-232C, let's just look at the basics.

RS-232C is a standard. It was set up by the Electronics Industries Association (EIA) to provide a standard interface for computer and peripheral manufacturers. The standard interface allows one manufacturer's computer to be used with another's printer or another's modem, etc. The standard, however, is not required. Some manufacturers don't use it. Those manufacturers that do, generally use a DB25 connector. As can be seen in Table 1, each pin has a designated name and function. Rather than discuss all of the pins, let's look at the three pins we'll be using for our printer interface.

The three pins we'll be using are pin 2, pin 3, and pin 7. Pin 2 is Transmitted Data (TD), which carries the data transmitted from the computer to the outside world. Pin 3 is Received Data (RD), which carries the data received by our computer from the outside world. Pin 7 is Signal Ground, which provides a ground return path for TD and RD.

The voltage levels used on the Transmitted-Data and Received-Data pins are also defined by the RS-232C standard. A mark, or logic one, will be a voltage level between −3 and −25 volts. A space, or logic zero, will be a voltage level between +3 and +25 volts. Since the RS-232C and TTL voltage levels are different, we need something to convert the levels from one to the other.

Several manufacturers build integrated circuits to do this conversion. The ones we'll be using are manufactured by Motorola. They are the MC1488 and the MC1489. The MC1489 is a quad line receiver. It is used to convert the received data

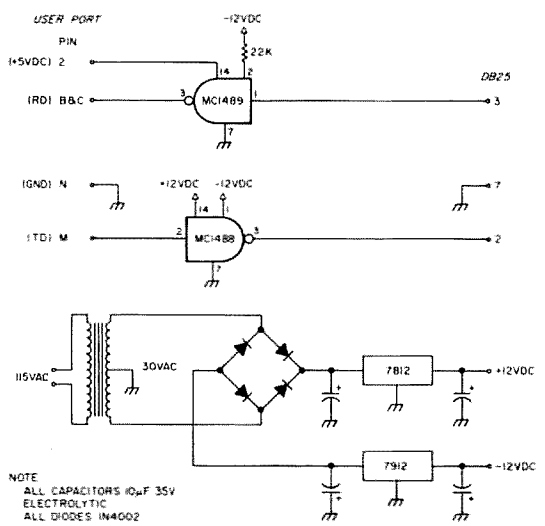

Fig. 1. Schematic.

Pin	Name	Function
1	FG	Frame ground
2	TD	Transmitted data
3	RD	Received data
4	RTS	Request to send
5	CTS	Clear to send
6	DSR	Data set ready
7	SG	Signal ground
8	DCD	Data carrier detect
9		Reserved
10		Reserved
11		Unassigned
12	(S)DCD	Secondary data carrier detect
13	(S)CTS	Secondary clear to send
14	(S)TD	Secondary transmitted data
15	TC	Transmitter clock
16	(S)RD	Secondary received data
17	RC	Receiver clock
18		Unassigned
19	(S)RTS	Secondary request to send
20	DTR	Data terminal ready
21	SQ	Signal quality detect
22	RI	Ring indicator
23		Data rate select
24	(TC)	External transmitter clock
25		Unassigned

1 =	50
2 =	75
3 =	110
4 =	134.5
5 =	150
6 =	300
7 =	600
8 =	1200
9 =	1800

Table 2. Data rate conversion.

from RS-232C levels to TTL levels. The MC1488 is a quad MDTL line driver. It is used to convert the transmitted data from TTL levels to RS-232C levels.

That's enough theory for now; let's look at the schematic (Fig. 1). As you can see, the circuit is fairly simple. All that's needed is a plus and minus 12-volt-dc power supply, one resistor, the two chips, and a couple of connectors. Since the circuit is so simple, go ahead and build the durn thing. When you're finished, come back here and finish reading. We still need to discuss some software.

Well, now that you've finished building the printer interface, you're going to need some software to make it work. There's a pretty good program on page 357 of the *Commodore 64 Programmers Reference Manual*. If typed in exactly as shown, it will transmit and receive ASCII data at 300 bits per second. If 300 is too slow or too fast for what you want to do, it's real easy to change. Line 100 reads like this: 100 OPEN 5,2,3,CHR$(6)

The number 6 in parentheses is what sets the computer to 300 bits per second. By changing this number to one of the numbers shown in Table 2, you can operate your computer from 50 to 1800 bits per second.

Other programs should work equally well. You'll probably find one that works better. Anyway, this one will get you started. Hope you enjoy building and using your printer interface as much as I did.■

PACKET RADIO GOES PORTABLE

GLB ELECTRONICS
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight.
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement:
9 to 15 Volts DC @ 25 mA typical

Dimensions:
4.6 X 5.90 X 1.0 inches

Total Weight:
12 ozs.

PKIL—Wired and Tested
List— $239.95
Amateur net— $209.95

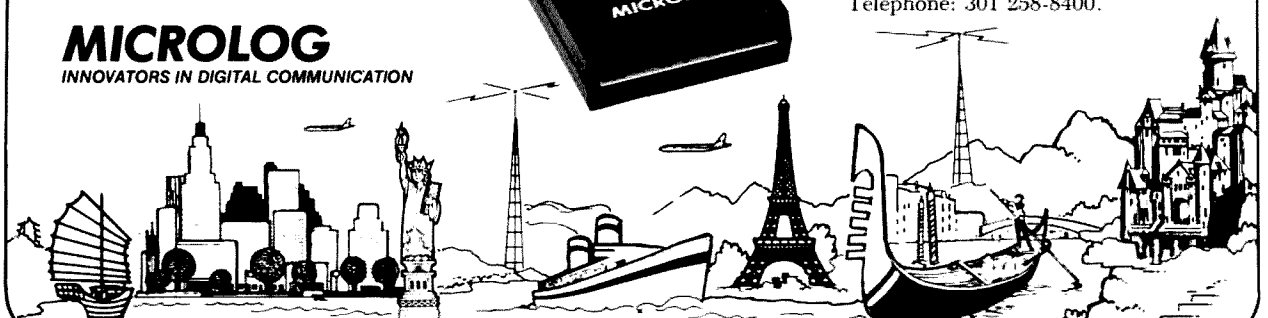
Copy Worldwide Short-wave Radio Signals on Your Computer

Remember the fun of tuning in all those foreign broadcast stations on the short-wave radio? Remember those mysterious sounding coded tone signals that baffled you? Well, most of those beeps & squeals are really digital data transmissions using radioteletype or Morse code. The signals are coming in from weather stations, news services, ships & ham radio operators all over the world. Our short-wave listener cartridge, the "SWL", will bring that data from your radio right to the video screen. You'll see the actual text as it's being sent from those far away transmitters.



The "SWL" contains the program in ROM as well as radio interface circuit to copy Morse code and all speeds/shifts of radioteletype. It comes with a cable to connect to your radio's speaker/earphone jack, demo cassette, and an excellent manual that contains a wealth of information on how to get the most out of short-wave digital DXing, even if you're brand new at it.

For about the price of another "Pac-Zapper" game, you can tie your Commodore 64, 128 or VIC-20 into the exciting world of digital communications with the Microlog SWL. $64. Postpaid, U.S.

The Perfect RTTY Filter

Its tunable shift covers 80 to 1160 Hz with a flat gain and Q. And you can build it for less than ten dollars!

Have you ever noticed just how un-standard the so-called standard RTTY shifts are in practice? 170-Hz shift seems to mean anything less than 400 Hz. In the past, every time I tuned in a nonstandard-shift RTTY signal, be it commercial or amateur, my longing for tunable filters only increased.

My quest for tunable RTTY filters has ranged from switched-capacitance active types (they never worked right) to an audio heterodyne system that was too complex to be worth the effort.

When I saw W9ODK's "Shoestring RTTY" TU using state-variable filters (*73*, January, 1985), the thought came to mind that such filters might be made tunable. The question was: Could the SVF maintain both Q and gain over the range needed to tune RTTY shifts of about 50 to 1200 Hz? A check of the filter design equations confirmed that such a filter should be possible, so two were built and tested. After a few kinks were worked out, a final unit was fabricated and installed in my demodulator.

The result was a continuously tunable filter allowing coverage of shifts from 80 to 1160 Hz. Tests showed both gain and Q to be nearly flat across the entire range.

The Circuit

Since many modern receivers have fixed bfo offsets and cannot pass the higher frequencies attendant to wider shifts, the final design was adjusted for so-called "low tones" (mark = 1275 Hz.)

The circuit (see Fig. 1) consists of two complete filters, each using a TLO84 BiFET quad op amp. The mark filter is fix-tuned at 1275 Hz while the space unit is tunable from 1355 to 2415 Hz. The pot used to tune the variable filter is a 100k dual-ganged, 41-step Radio Shack model (217-1732). The pot is billed as a "Stereo Control" and each section has a 40-percent-loudness tap which is unused.

R5 and R6 could be eliminated if a suitable 50k pot is available. Several junk-box pots were tried but produced poor results because the gangs were not evenly matched.

R3 and R4 should be closely matched as should

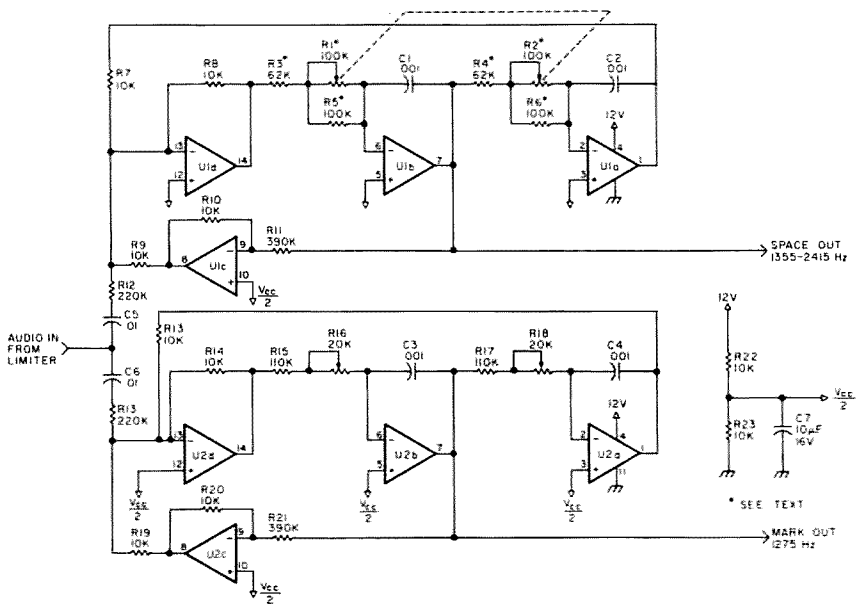

Fig. 1. Tunable RTTY filter.

Filter Center Frequency (Hz)	Shift (Hz)
1355	80
1445	170
1600	325
1700	425
1825	550
1975	700
2125	850
2275	1000
2375	1100

Table 1. Common shifts and their corresponding space-filter center frequencies.

R5 and R6. These resistors will determine the high and low end of the filter tuning range.

Construction

Just about any circuit-fabrication method can be used. I built mine on a PC card as a direct plug-in replacement for an existing filter card. The tuning pots replaced the filter switch on the front panel. Whatever the method of construction, keep in mind that some layouts may require the taming effects of ferrite beads on some or all of the inputs, outputs, bias lines, and the power-supply lead.

Also, do not lace or bundle the tuning control leads. The stray capacitance may cause problems, especially if the leads have to be more than a few inches long. Use polystyrene or mylar™ capacitors for C1 through C4. I used 15-turn PC trimpots for R16 and R18, but that is not really necessary.

Parts List

C1–C4	.001 mylar or polystyrene	$ .48
C5, C6	.01 disc ceramic	.16
C7	10-uF, 16-V electrolytic	.18
R1, R2	Dual-gang 100k pot (RS 271-1732)	1.79
R3–R15	¼-Watt resistors	.78
R16, R18	PC-mount, 20k trimpots	.50
R17, R19–R23	¼-Watt resistors	.36
U1, U2	TLO84 BiFET quad op amp	3.90
Misc.	2 14-pin DIP sockets, hookup wire, PC board, etc.	1.00
		$9.15

Parts available from Radio Shack, and Jameco Electronics, 1355 Shoreway Rd., Belmont CA 94002.

To align the fixed filter, feed in a 1275-Hz signal and adjust R7 and R8 for maximum output.

The variable filter should not need any alignment. To check it, however, feed in different tones and adjust the tuning control for maximum output. In each case, the output voltage should not change with frequency. Also, the output voltage should equal that obtained from the fixed filter, although a slight falloff may be noted at the extreme end of pot rotation. If the readings vary by more than a few tenths of a volt, check to see that both gangs of the tuning pot track together.

Results

While the gain and Q of the space filter are nearly flat across the entire tuning range, some interaction and phase shifting will be noted on shifts less than 125 Hz. This is easily overcome with a slight retuning of the receiver.

The filter is easiest to use when coupled with an oscilloscope. Tune the receiver until the mark signal yields maximum scope deflection, then rotate the filter-tuning control until the correct pattern or maximum space deflection is obtained. After years of switching filters, it takes a little getting used to.

Of course, if these filters are used with an AFSK generator for transmitting, make sure the tones transmitted are the same as those received. Otherwise, you will not be transmitting and receiving on the same frequency.

If the filter control is calibrated, then you can tell if that signal is 800- or 875-Hz shift. See Table 1 for a list of space-filter center frequencies and the corresponding shifts. The list can be used as a calibration guide.

With these filters, straddle tuning is no longer necessary. No matter what the shift, the maximum signal is being delivered to the detectors. ■

Double Your Computing Power!

Try "parallel processing" with a second CoCo keyboard.

This article describes how to add a second keyboard to your computer. It is simple in that no code conversion is attempted. The second keyboard is simply placed in parallel with the first. This will be of special interest to amateur-radio operators using the Color Computer.® They no longer will have to have the computer sitting in front of their radios taking up valuable desk space.

My wife and I run a secretarial service here in the Cleveland, Ohio, area. We have found our CoCo to be invaluable in this word processing area. The TRS-80C makes the thousand-dollar machines look like a big waste of money. Why buy a big, sometimes dedicated, machine when you can run two or even three CoCos for the same price? I do not believe that we realize how many computers like ours are out there in businesses. More public-domain programs to demonstrate the business end of the Color Computer would drive this home.

Although not into games, I do use the computer for code conversion on my amateur-radio system. As an avid code/radioteletype enthusiast, I cannot imagine going back to a keyer or mechanical teletypewriter. My Yaesu FT-980 radio is microprocessor controlled. The various ports are brought out of the radio and can be controlled by another microprocessor. The possibilities are exciting.

My problem was described by the old adage, "You can't mix business with pleasure." The CoCo had been kept on the radio desk. This allowed me to enter business documents while still keeping an ear to the radios. At times the CoCo really became a nuisance as it took up so much desk space; moving it to the side is difficult due to the wires and cables.

Checking some of the local computer outlets, I found their units to be (typically) way overpriced. Keyboards are available through mail order, but matching enclosures could not be found. Many of these keyboards would require reformatting to work with the Color Computer.

This was when our 16-month-old daughter came by with her "computer"—the old bubble-bump key-

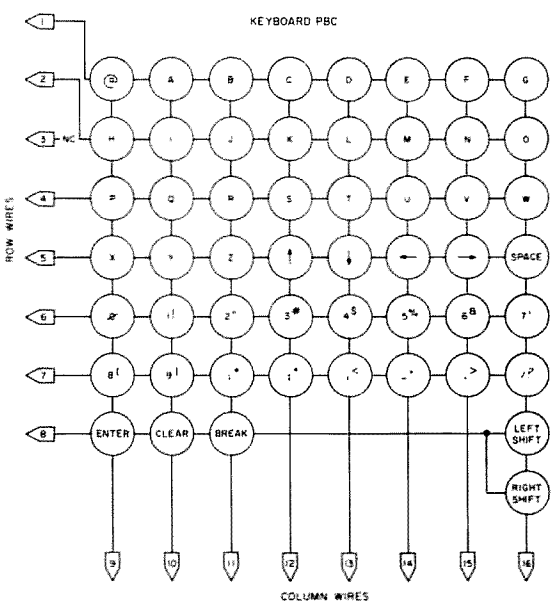

Fig. 1. To test your new keyboard, connect a battery-operated test lamp or an ohmmeter between any row and any column wire. Ensure that the respective key operates. For example, if wire 4 and wire 13 are checked, key T should establish continuity. Repeat for each row and column wire.

Photo A. The new addition to the radio shack.

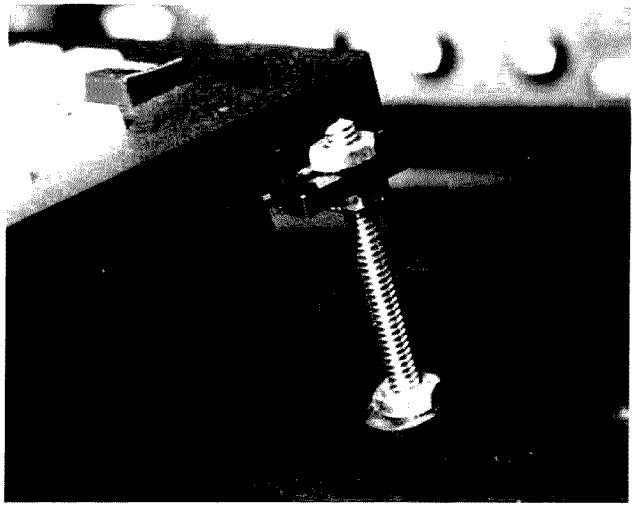

Photo B. Keyboard rear leg with rubber foot.

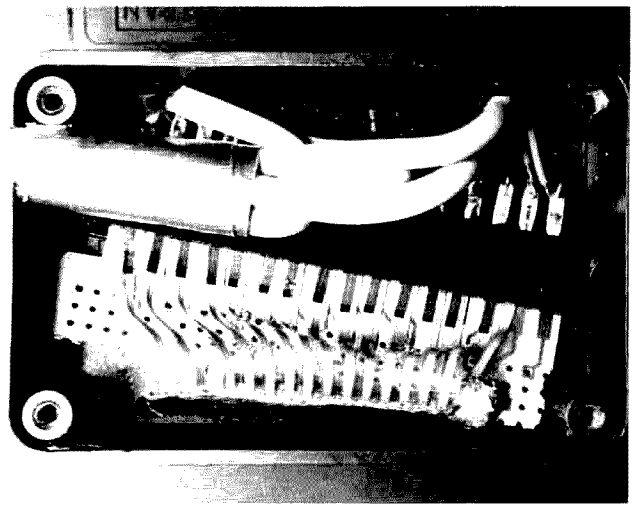

Photo C. Box for connections.

board which I had given her when I modified my computer by giving it a real typewriter keyboard. My wife yelled, "Indian giver!" as I took the old keyboard into the workshop.

Modifying the Keyboard

The keyboard is a small, self-contained unit not needing an enclosure. However, you will need a box to keep the connections immobilized. If they are bumped and jiggled, they will eventually fail. The mounting brackets on the side provided a location for hardware rigged to hold the keyboard at the proper angle.

All parts were scavenged from various junk boxes. A parts list is an excellent breeding ground for creativity. If you do not have a part, try to come up with something you can substitute for it. If you do not have rubber feet for the keyboard, perhaps you can locate some rubber-like material from somewhere else, or check the attic and basement for some discarded appliance that may have rubber feet you could use.

The keyboard is connected to the computer via the 16-conductor ribbon cable coming out of the back of the connector box. (Pin 3 of this cable is not used: I write about 16 conductors only because of the type of wire that I used. You may substitute 15-conductor cable anywhere that 16-conductor cable is called for.)

Cut a slit in the bottom of the box for the ribbon cable to fit through. Measure the cable and mark the box. Drill a hole at one end of the mark, fit a coping-saw blade into it, and carefully cut the line. If you do not have a coping saw, perhaps the slit could be made (in a plastic box) using a hot knife or soldering iron. A hand mototool would be ideal for this step. Wrap tape around the ribbon conductor to protect the cable from chafing on the edges of the slit in the box.

The following step, cutting and gluing the ribbon cable, is not necessary if you can locate a proper connector for it. You cannot solder against the plastic of the cable; it just disintegrates.

The connection to the keyboard is formed using a card-edge socket and a plug-in board for this socket. Since the spacing of the connections on the ribbon cable is different from the spacing on the plug-board, the ribbon cable connections will be repositioned to match the plug-in board. With a pair of scissors, cut the conductors of the ribbon cable apart. Feed the cable through the slit and glue the box to the back of the keyboard.

Sixteen-conductor cable will be run from the second keyboard to the computer. This cable can be hard to find, but it is easy to fabricate. Rotor cable in 3, 4, and 5 conductors is available at most department stores. Four-conductor phone line can be found at Radio Shack and is quite flexible.

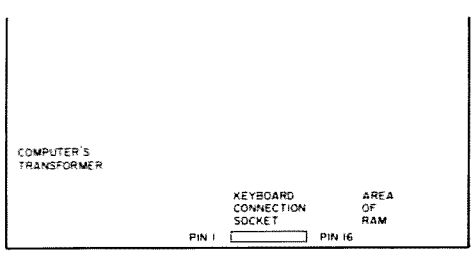

Fig. 2. Front of the computer.

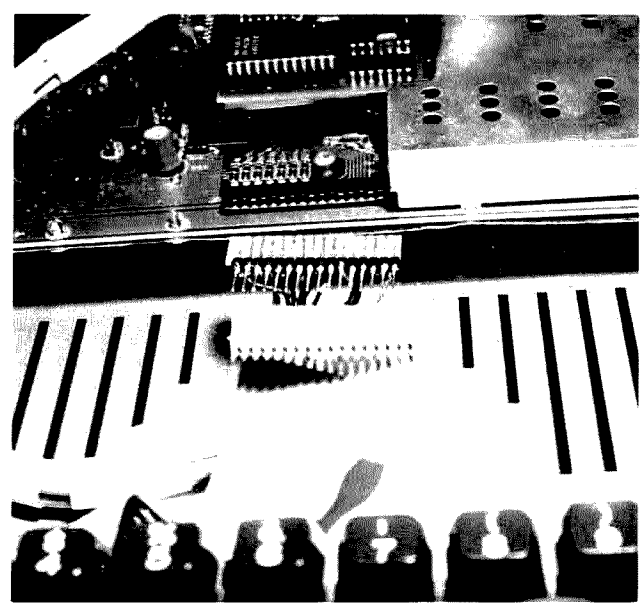

Photo D. Keyboard connectors come into the bottom of the computer.

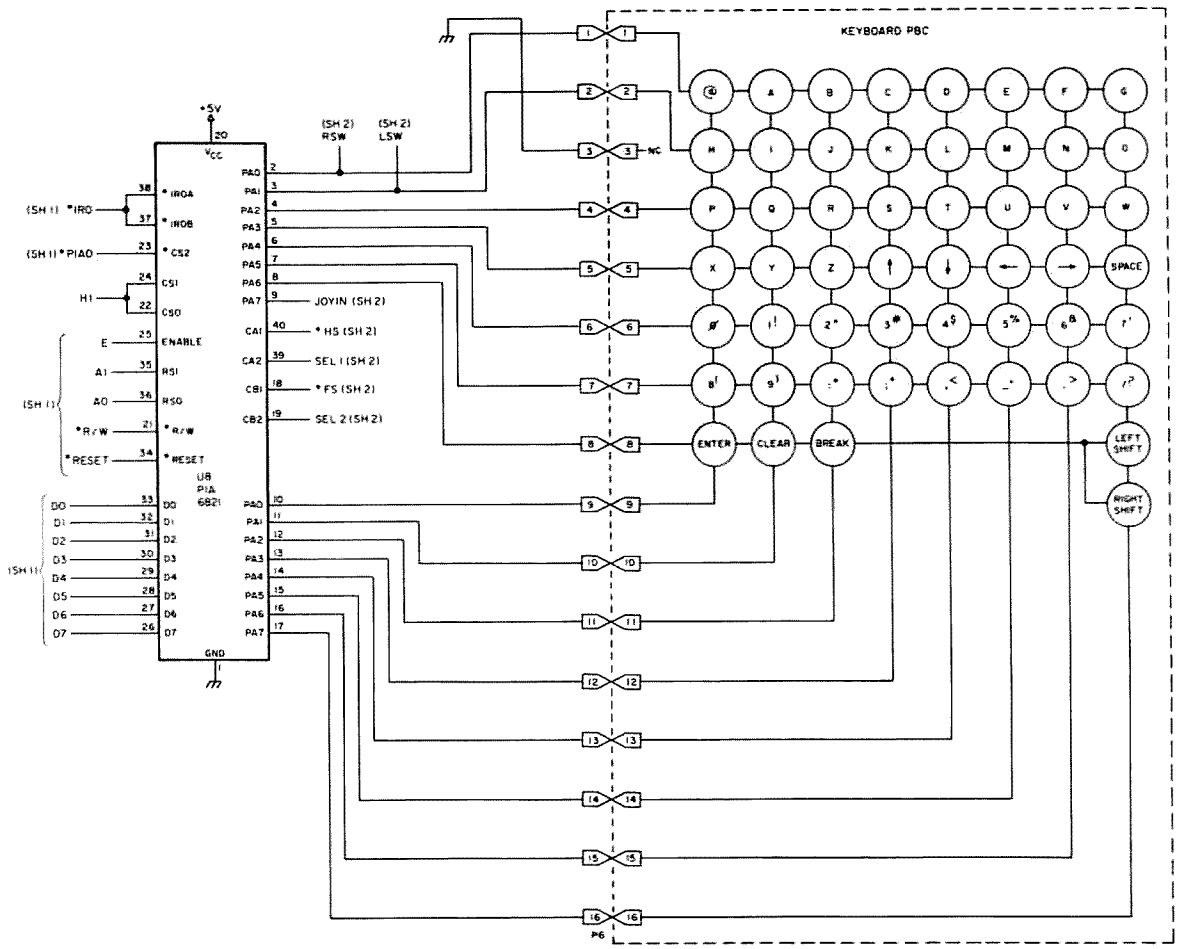

Fig. 3.

Determine how far you want to go with the keyboard and cut as many runs of the cable as you need to make the 16 conductors. I used 4-wire phone line, 25 feet long; four runs made 16 conductors. Tape the cables together every six inches or so to keep things neat. Masking tape is cheaper than electrical tape for this purpose.

Now you will have to decide if you wish the second keyboard to have a connector. The alternative is to wire the keyboard directly to the computer. This means you will have to gather up the extra keyboard with the computer when you move them. Skip the next few steps, which are for the connector, if you are not going to use one.

Cut another 16-conductor cable; this time make it two feet long. It will be used inside the computer. Set it aside.

A 25-pin D connector is used in these steps. These connectors are difficult to solder. A small soldering iron and tweezers will make the job easier. Shorts can be avoided by using as little heat as possible so that the insulation on the wires is not burned away.

Solder each set of wires in a predetermined order. If you solder red, black, green, and yellow each time, you need find the position of only one wire to know where the other three go. If you are using rotor cable, you will find one wire is different. Again, pay attention to the order in which they are installed.

Use the female connector for the back of the computer. If something falls on the computer, it is less likely to short the female connector than the male.

Take one end of the 16-conductor cable you fabricated and solder it to the male D connector. Install the hood over this connector. Set the cable aside.

If the box that was installed on the back of the keyboard is too small to fit the card-edge socket, the socket will have to be cut. Cut between the 17th and 18th set of terminals on one side of the socket. That way you will not need to worry about damaging the 16th terminal. If more room is needed, cut off the mounting hole. Only the top or bottom set of terminals will need to be used. The other set of 16 terminals can be cut off.

Cut the plug-in board perpendicular to the terminals. Leave enough to be able to grasp the board to plug it in. If you cut the connector, cut the board's length to match.

Using the plug-board as a guide, glue the ribbon cable terminals over the plug-board terminals. Super glue, if used carefully, works fine. The connector will be tight due to the additional material of the ribbon conductors so be sure your glue will hold.

Use an ohmmeter or battery-operated test lamp to determine which wire of the cable is attached to pin one of the D connector. Solder this to the terminal on one side of the card-edge socket. Do the same for the 15 other wires.

Plug the board into the card-edge socket. Place the connection into the box. If it is loose, a drop of glue will

secure it. File a hole in the top of the box for the cable to come out. Put tape over the cable so it fits tightly in the hole. Put the cover on the box.

Glue two rubber feet on the bottom front edge of the keyboard. Threaded rod is used to lift the back of the keyboard to the proper angle. Cut the rod so that it gives an angle that will suit you. Two nuts secure the rod to the top of the keyboard. Put a nut onto the bottom of one of the rods and screw a rubber foot on after the nut. Glue the nut to the foot. Do the same for the other rear foot. A dab of glue to all the nuts will keep things secure.

Modifying the Computer

Unplug the computer and take the top off. The female D connector is installed on the rear of the cover over the output ports. Install it with the flange on the inside of the cover.

Mark where the hole should be placed and cut it out. A coping saw works well here, too. File the hole clean and make sure it is large enough to allow the male connector to fully seat in the matching cover. If the hole is too small, the connector will get hung up on the cover plastic and will not fully seat. Drill the two mounting holes.

Prior to mounting the connector, attach the two-foot piece of 16-conductor wire. Two washers on the outside of the connector's mounting bolts will keep them from digging into the plastic of the computer case. Bolt the connector in.

Attach the connectors together. Use Fig. 1 to check the keyboard for proper operation. Put a bit of tape over the wires to indicate their respective pin numbers as you check.

Remove the CoCo's keyboard. (I had replaced the original with a Hi-Tek keyboard which came with an adapter that slides into the CoCo's keyboard connector. It was a very easy job connecting the cable to this connector. I just slid it out a bit, soldered the wires to the very back of the pins, and slid the connector back in. If you do not have this adapter, try sliding the wires into the connector with the wires of the other keyboard and tape the two sets of wires together.)

Now is a good time to check for problems with your typewriter keyboard. Sometimes the larger keys, the <Enter>, <Shift>, and <Space Bar>, will begin to bind. On most units the key-tops are easily pulled off. A dab of Vaseline will restore proper operation.

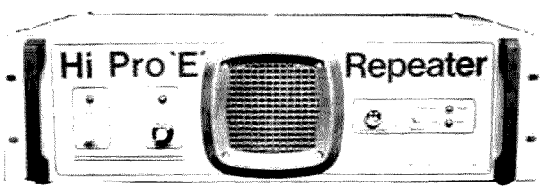
Button up the computer and plug it in.

One More Thing...

You now have a second, small keyboard on your computer. As you can see in Photo A, it can easily be moved out of the way of the radios. I will eventually change to an "expensive-grade" keyboard, but for now the CoCo's old keyboard fulfills all my needs.

Oh, one more thing. If one feels guilty about stealing a keyboard from a toddling daughter, just take her out for some ice cream. The whole TRS-80C probably will be hers before long. ■

Parts List



An old (or new!) CoCo keyboard
16-conductor cable (see text)
Small plastic box (270-230)*
Male D connector (276-1547)
Female D connector (276-1548)
Hood for D connector (276-1549)
Card-edge socket (276-1551)
Card-edge board (276-152)
Four rubber feet
About 6" of threaded rod
Six nuts to fit the rod
Masking tape
Super glue

* Radio Shack part numbers.

Hi Pro 'E'

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.
• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.
• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

Working 2ICTU

Can RTTY get any simpler?

Those of you expecting a rare DX story are probably going to be disappointed. But if you're interested in trying RTTY and have a computer, you should find this article interesting. If your computer has a serial port, you can put it on the air with just two ICs and a handful of small parts. This provides a very simple and, most important, inexpensive way of trying your hand at RTTY.

Some time ago I built a function generator to help out with various projects around the shack. It's based on an EXAR 2206 IC which does all the work. While studying the spec sheets on this device, I noticed that it could also be used for FSK generation. Further digging around showed that EXAR also makes an IC that will demodulate FSK tones. These two devices seemed ideal for the construction of an ultra-simple TU that would interface my computer to my ham station. So, armed with the excellent data sheets provided by EXAR, I set out to build a RTTY terminal unit. The result is a compact and simple AFSK TU that works surprisingly well.

The 2ICTU serves a number of purposes around the shack. In addition to the fun of making RTTY contacts over the air, it has proved a useful accessory for my computer. It allows me to send programs over the air, which is a neat way of sharing my latest programming wizardry with friends who have otherwise-incompatible hardware. It also provides a way of backing up my more important software by running it out to audio tape. That way, if my disk drives or main tape unit go fratz, I am not completely out in the cold while

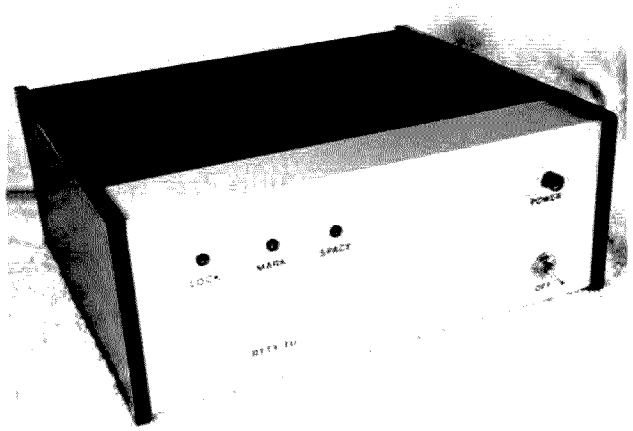

Photo A. The completed 2ICTU. I like to give my projects a professional look, so I use Ten-Tec enclosures. They cost a little more, but I believe they are worth it. The mark and space LEDs were never implemented; they're not really necessary.

Photo B. The rear panel with the multitude of connectors for the various inputs and outputs. The 5-pin DIN connector is used for the hookup to the serial port. The label indicates the 3 pins used: transmit data, receive data, and ground. The switch is for reversing the "sense" of the RTTY signal via the exclusive OR gates on the serial board. The audio-level trimpots are visible below the audio and tape outputs. The "audio" input and output are used for the connections to the rig.

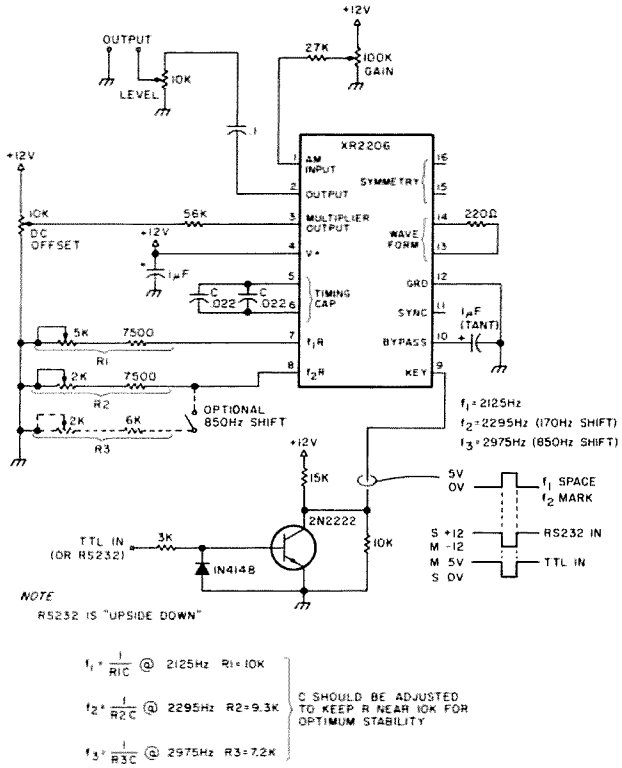

Fig. 1. The AFSK unit.

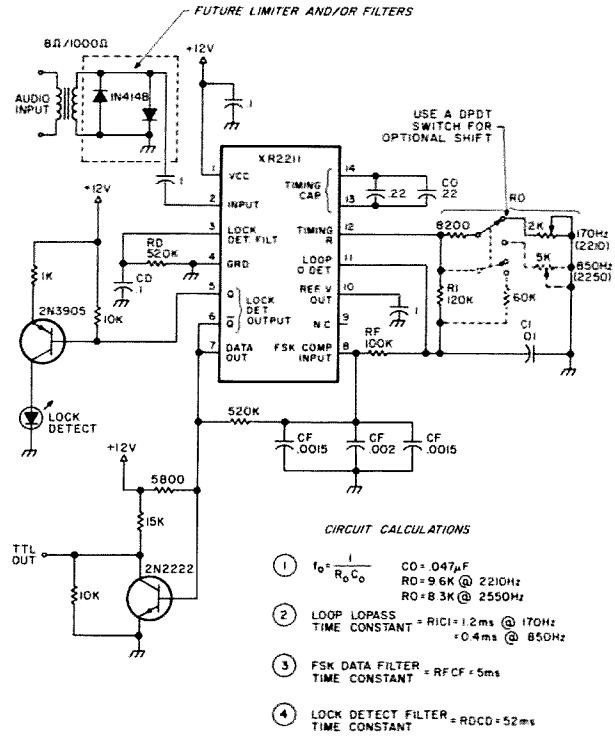

Fig. 2. The AFSK demodulator.

repairing them. Backup on a completely different medium such as this is the most secure way of protecting yourself from total disaster.

For those of you who may not have a serial port with a controllable baud-rate generator on your system, I have also included my general-purpose serial port. It is designed for the S-100 bus, but with a little thought can be modified for any computer. The configuration of the hardware makes it particularly easy to modify for the Commodore 64 or VIC-20 or any other 6502-based system. I have included the necessary circuit changes for those of you with these computers who might like to build the 2ICTU.

The modular concept of the 2ICTU should make it easy for you to extract only those parts required by your particular combination of computer and radio gear. It also allows you to plug in any additional items you might like, such as additional filters, blinking lights, etc.

The software is what really makes the 2ICTU shine. A good software package makes this minimal hardware perform like a much more expensive unit. What's more, since it's my package, I can get into it and tinker around to my heart's delight. Anything I want to add or change is a simple matter of changing the coding to customize it to suit my needs and desires. I wrote some simple machine-language routines to interface the computer to the 2ICTU for storing and recalling data and programs on audio tape. The "bells and whistles" program for the RTTY operation is written in Fig-Forth and provides many of the features of store-bought units, including split video for transmit, receive, and status portions of the screen.

Construction can be by whatever method you like; there's nothing critical or tricky about the circuits. Normal good building practices should provide you with a quality finished product. I built the 2ICTU on a surplus wire-wrap card and it has performed flawlessly for the past two years.

The AFSK Unit

The AFSK unit is an EXAR 2206 IC (see Fig. 1). This single chip does all the work and requires only that we add the required timing components to obtain the necessary frequency outputs. The schematic is straightforward and the only critical parts are, as usual, the timing capacitors—they should be polystyrene for maximum stability. No CW ID is provided since there are many and varied ways of accomplishing this depending on the hardware available in your particular circumstance. You should have little trouble adding one that suits your system. I built the 2ICTU for narrow-shift operation only, but have included the necessary parts for both narrow and wide shifts.

I won't bore you with a lengthy technical description of the circuit since the schematic is pretty self-explanatory. I recommend that you obtain the excellent data sheets provided by EXAR when you get your ICs. They will provide all the information you might want about this device. Indeed, the circuit shown is basically taken from the applications part of these sheets.

Tune-up is best accomplished with an oscilloscope and a frequency counter. First, adjust the dc offset and the gain trimmers for the best looking sine wave at pin 2. Next apply +5 volts to the input and adjust the mark frequency trimmer for 2295 Hz at pin 2. Then ground the input and adjust the space timing trimmer for 2125 Hz at pin 2. If you included the parts for the 850-Hz shift, also adjust the mark frequency for it. Finally, readjust the dc offset and gain controls for the best looking output. Keep the gain at the minimum level that provides a clean signal.

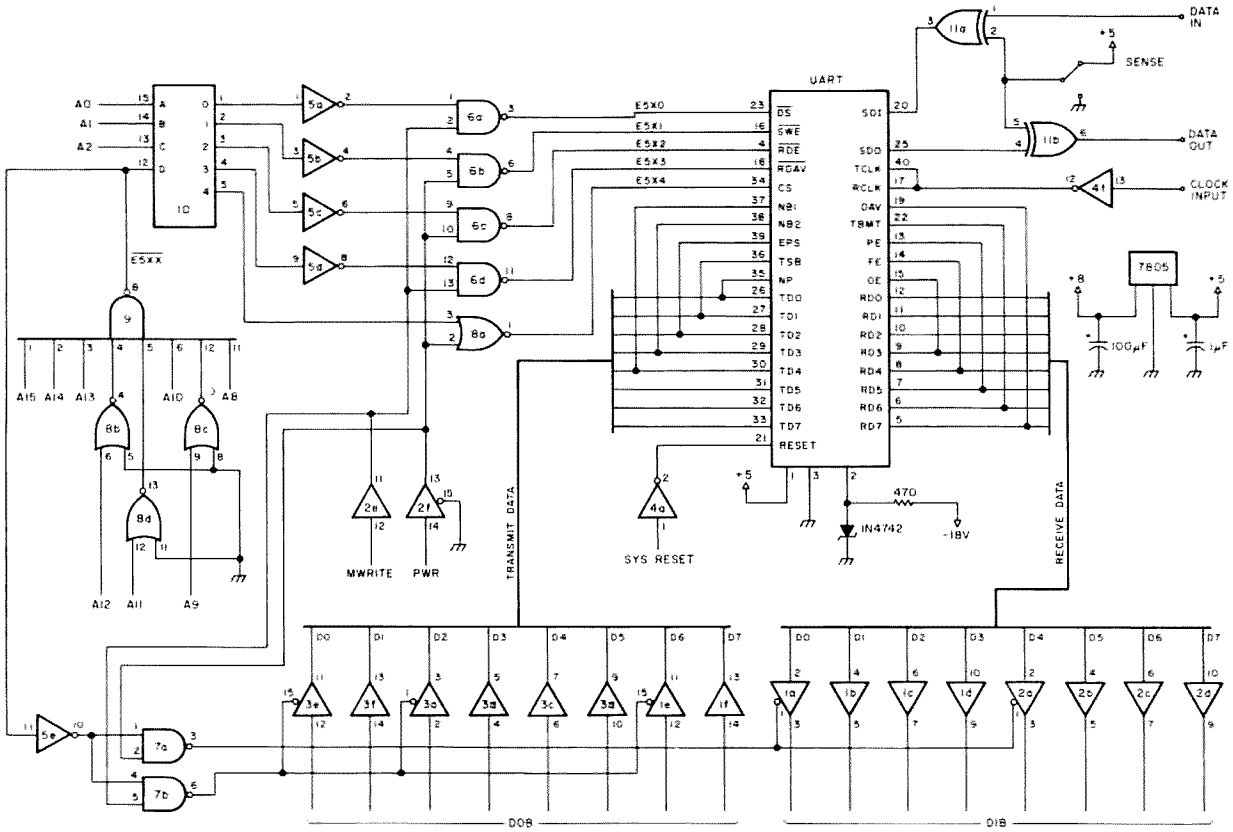

Fig. 3. The general-purpose serial port.

The 2206C provides an extremely stable and clean AFSK output. No distortion is introduced at the critical frequency transition point since the output is phase-continuous during this time.

The Demodulator

The demodulator circuit is as simple as the AFSK generator (see Fig. 2). I left plenty of space on my board for future filtering circuits but found that the built-in one works so well that I just never got around to it. An EXAR IC does all the work again, but this time it is the 2211. Once again, I recommend that you obtain the data sheets with the IC. They contain a wealth of information and will give you all the technical data you might want.

The gang of capacitors hanging off pin 8 provides the necessary FSK data filtering. Calculated values for these things seldom come out near anything standard, so the parallel group gets us close. As before, timing capacitors should be polystyrene for maximum stability. My system required only TTL levels so I did not include the added complexity of an RS-232 output (although the AFSK unit will accept RS-232 input levels). If your port requires these levels, you will have to add the necessary parts.

To tune the demodulator you will need only a frequency counter to adjust the center frequency of the internal vco. You do this with the lock-detect filter disconnected and no input signal. The easiest way is to remove the IC from its socket (you did use sockets, didn't you?) and carefully bend pin 3 out just enough so that it is out of the socket when you plug it back in. Now jumper pins 10 and 2 together, apply power, and adjust the trimmer (or trimmers) for the correct frequency at pin 3. This will be 2210 Hz for narrow and 2550

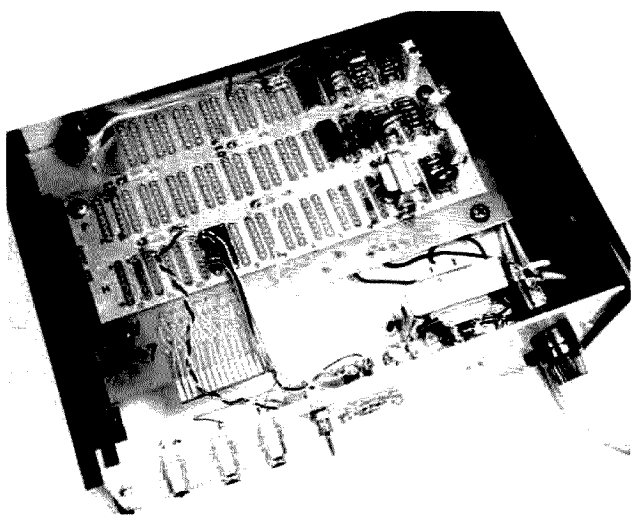

Photo C. The innards of the 2ICTU. As seen, there is plenty of room for expansion! The two EXAR ICs can be seen at the upper-right corner. In the lower-right corner is the 12-volt power supply. Just about anything will do since very little power is required.

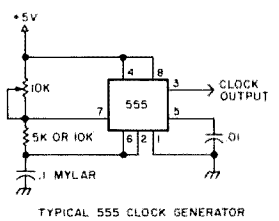

Fig. 4. Typical 555 clock generator.

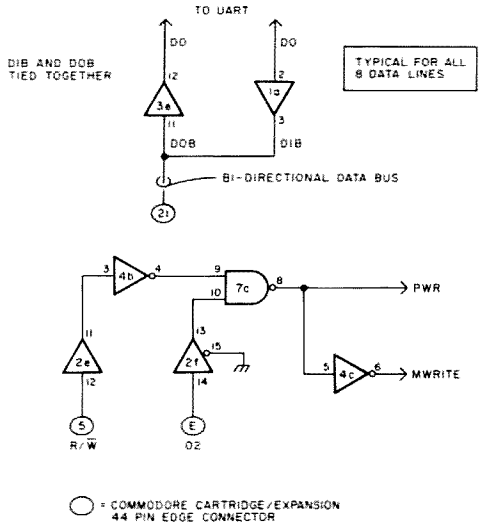

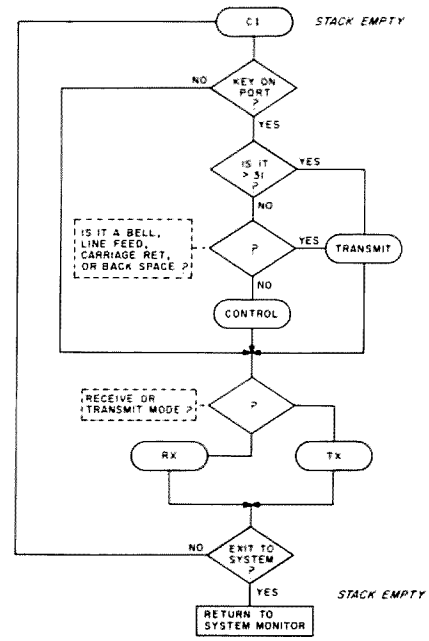

Fig. 5. Serial-port connection for Commodore computers.

Hz for wide shift. When done, restore pin 3 to its normal position.

In operation, tune the received signal until the lock-detect LED is on continuously. A flickering LED indicates improper tuning or a signal that is too weak. While the 2ICTU will certainly not match the performance of expensive commercial terminal units, I was quite surprised at how weak and noisy a signal the 2211 will copy. It does reasonably well even in QRM when the signal you wish to tune is stronger than the surrounding ones.

General-Purpose Serial Port

The serial port is not quite as simple as the 2ICTU (see Fig. 3). Still, it's pretty straightforward and not difficult to build. It uses a plain old garden-variety UART which does the majority of the work. The other ICs provide the necessary buffering and address decoding. The exclusive OR gates on the serial input and output provide for selectable "sense" on the RTTY signal.

The serial port as shown was designed for the S-100 bus. It does not, however, use the standard S-100 port-addressing method. I chose instead to implement it as a few memory addresses at the unoccupied end of my RAM space. I prefer memory-mapped I/O, and it suits the 6502 microprocessor used in my system. If your computer uses all available memory space or if the addresses shown are used, you will have to revise the addressing scheme to suit your system.

The address decoding is done by ICs 8, 9, and 10. As shown, they decode one page of addresses between E500 and E5FF hex. Only 5 locations are actually used.

The first location, E500 hex, is the transmit-register buffer of the UART. Data written here is converted to serial output at pin 25 of the UART. The necessary start, stop, and parity bits are determined by the word previously stored in the control register at E504 hex.

The second location, E501 hex, is the UART's status register. Reading this address places the status of the UART's operations in the high 5 bits of the returned-data byte. The overrun, framing, and parity-error bits are returned in bits 3, 4, and 5 respectively. If any of these are set, an error is indicated. Bit 6 is the "transmit buffer empty" flag. This bit must be interrogated and must be true prior to writing any new data to the transmit-register buffer at E500 hex. Bit 7 is the "data available" flag for received data. A true condition indicates that the UART has received a data word and it is available in the received-data buffer at E502 hex. Bits 0, 1, and 2 have no meaning. Bits 6 and 7 were chosen for the two busiest functions because they are simple to use for control of program execution in the 6502.

The third location, E502 hex, is the actual location of the received data. After determining that data is available, by bit 7 of E501 being true, a read of E502 returns the received-data byte.

After reading the received data, a write must be performed to location 4, E503 hex. This clears the data available flag for the next byte. The data written has no meaning since it is not actually used.

The fifth location, E504 hex, is the control register of the UART. A data word written here sets the various parameters required for the UART's operation. Bit 0 controls the use of a parity bit. When it is reset, or equal to zero, no parity is generated or checked. Bit 1 controls the number of stop bits appended to each serial byte transmitted and the number checked on each received byte. Zero equals one stop bit, while a 1 equals two stop bits, or, in the case of 5-bit words, one and one-half stop bits. Bit 2 is used to choose even or odd parity when parity is selected via bit 0. Bits 3 and 4 determine the length of the transmitted or received word. 00 equals 5-bit words, 01 equals 6-bit words, 10 equals 7-bit words, and 11 equals 8-bit words. Bits 5, 6, and 7 are not used. The control register is write-only. Once a control word is stored here it will remain active until it is changed. For Baudot code, I normally store an 03 hex and for 8-bit ASCII I store 19 hex.

Parts of ICs 5, 6, and 8 are used to gate the appropriate read and write signals to the UART. Two gates of IC 7 and one from IC 5 are used to control which set of buffers is activated, depending on whether a read or write operation is being performed. IC 11 is used to control the sense of the transmitted and received word for true or inverted RTTY. The actual control is performed by a

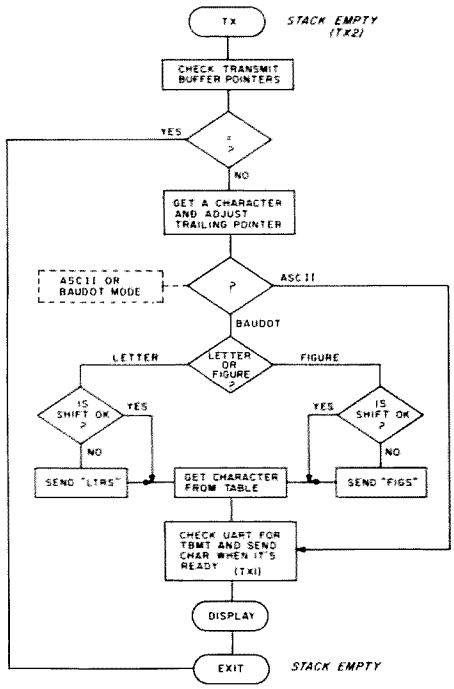

Fig. 7(a). The transmit module (TX).

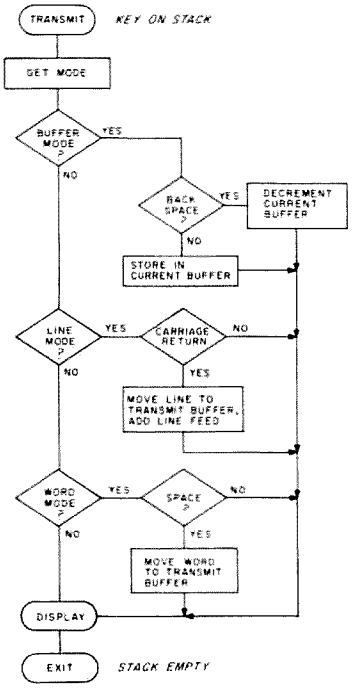

Fig. 7(b). The transmit-buffer control (TX).

SPDT switch located on the front (or in my case, the rear) panel of the TU. The data input, IC 11, pin 1, is connected to the FSK demodulator output and the data output (IC 11, pin 6) is connected to the FSK generator input.

I use 6522 VIAs for my system I/O. These are similar to the ports used in the Commodore 64 and VIC computers. The neat thing about these devices is that they each contain a pair of software-controllable timers. These timers are extremely useful, particularly where the 2ICTU is concerned. One of the timers can be configured to output a controlled square wave at bit 7 of the B port. By loading the appropriate 16-bit numbers in the count registers, I can generate any of the frequencies needed to operate the serial port for RTTY. The numbers I use for my 1-MHz system are 686 decimal for 60 words per minute (45 baud), and 282 decimal for 100 words per minute (110 baud). These numbers probably will differ on your system since no two clocks are ever quite the same. Different timer types also require different approaches. I found that the best way to determine the correct figures was to connect a frequency counter to the output and experiment with different values until I found the ones that gave frequencies closest to the ones I desired.

If no timers are available on your system you will have to provide a 555 or similar type clock generator for each of the two popular baud rates. A typical circuit is shown in Fig. 4. The clock frequencies required are 16 times the baud rate or 720 Hz for 60 wpm and 1760 Hz for 100 wpm. Two separate 555s are easier because, as you can see, the two frequencies do not share a common multiple.

Those of you with Commodore computers can modify my serial port for your computers quite easily. It is necessary only to combine the two data buses (DIB and DOB) into a single bi-directional bus and to synthesize the S-100 MWRITE and PWR signals as shown in Fig. 5. Your system reset signal will work as is. The 6526 ports in the Commodore computers contain a pair of timers like those in the 6522. You should be able to use these by connecting pin C of your user port to the UART's clock input at pin 13 of IC 4. The timer will, of course, have to be configured and initialized by your software. To configure the timer, load a C0 hex into the auxiliary-control register. The ACR is located 11 (decimal) locations above the base address of the port. Then load the 16-bit-count word into the counter latches at base +6 (low order) and base +7 (high order). The timer is started by storing the high order count into base +5 and stopped by storing zero into the ACR (base +11) or by doing a reset.

Software

That brings us to the software required to make this minimal hardware perform like an expensive RTTY unit. As I stated earlier, my software for RTTY operation is written in Fig-Forth. I urge any of you thinking about trying Forth to do so. It is an excellent language for just about any application. Like any new language, it may seem confusing and difficult to understand at first, but once you've worked with it for a while, you'll find it quite easy and natural to use. The RTTY program is contained in 25 screens of text. Each screen is a 1024-byte block of ASCII data arranged as 16 lines of 64 characters. I have included only the flowcharts with this article in the interest of keeping it compact.

For those who desire a complete listing, I can provide one if you send $5.00 to cover the cost of duplication and mailing. Also, I can write the screens onto 8-inch disks for single-density CP/M or OSI systems if you send a disk and $5.00. Obviously, the disk would only be of use to those of you with working versions of Forth. If you don't have Forth, or wish to try it, then you should be able to write the program from the flowcharts in your favorite language. Whatever language is used, it must be able to keep up with the many real-time events taking place si-

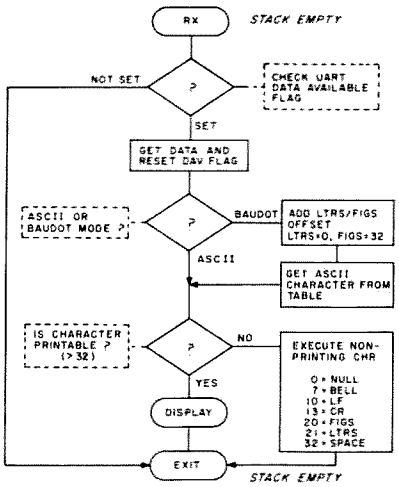

Fig. 8. The receiver module (RX).

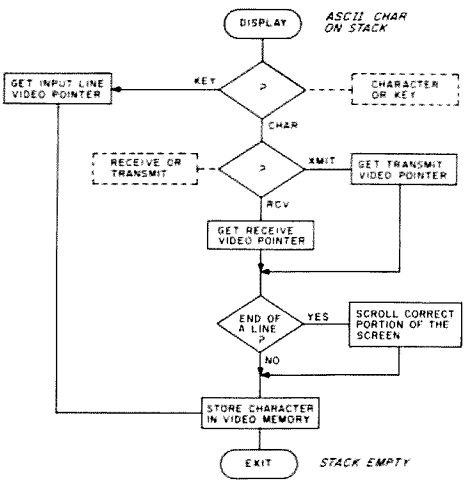

Fig. 10. The display module (DISPLAY).

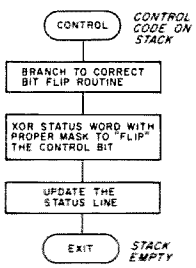

Fig. 9. The control module (CONTROL).

multaneously. A slower language may have to resort to interrupt routines in some key areas. Forth is fast enough that it can handle everything "on the fly."

The program consists of six main modules. These are named CI, TX, RX, CONTROL, DISPLAY, and TRANSMIT. CI is the command interpreter. TX is the routine that constructs the data byte to be transmitted. RX decodes the received byte and either displays it or executes some function. CONTROL accepts a control character from the keyboard and performs the requested action, such as changing baud rates, activating automatic unshift on space, etc. DISPLAY handles the printing of characters on the video monitor and the line printer. And finally, TRANSMIT keeps track of which buffer transmit data is stored in and taken from.

The heart of the program is the command interpreter, or CI (see Fig. 6). All program functions begin and end here. CI's main task is to accept input from the keyboard and to take some action based on it. If no key is present, the routine examines a flag to see if we are currently transmitting data. If we are, it transfers control to TX to see if it is ready to send another character. If we're not transmitting, control is transferred to RX to see if it has a received-data byte for us. Both of these routines process one character at a time and then return to CI.

If CI detects a key input, it gets the key data and decides what to do with it. Certain control codes may be transmitted, so these are passed to TRANSMIT for placement in the current buffer. Other control codes tell the program what we would like to do, such as turning the printer on or off, changing the transmit buffer pointer, etc. These are passed to the CONTROL module. If the key data is not a control character, then it is passed directly to TRANSMIT which stores it in the current buffer for TX to send when its turn comes.

TX checks the current buffer pointer to see if there is anything for it to send—see Fig. 7(a). If there is not, it simply returns to CI. However, if there is, a number of things happen. First, we must check a flag to see if the intended transmission should be in Baudot or ASCII. If it's ASCII, we simply send it on its way since that's the way we stored it in the buffer. But if it's Baudot, we have some work to do first. We must look at the character and decide if it's a letter or figure. Once this is decided, we send the proper shift, if necessary, and then convert the ASCII character to its equivalent Baudot code. Finally, we send it on its way through the ether to the fellow ham anxiously awaiting it on the other end of the QSO. This is done by checking our UART for a "transmit buffer empty" condition and, when it's ready, simply storing the data byte at E500 hex. The UART then converts it to serial data and sends it to the 2ICTU where it is converted to the proper audio tones for transmission by your ham station. We also simultaneously show it on the transmitted-text portion of the video monitor and print it on the printer if so desired.

When RX (Fig. 8) is called by CI, it first looks at the UART status register to see if a received character is ready. If not, it exits immediately back to CI. If it does find the data-available flag set, it gets the character from E502 hex and then resets the DAV flag by writing to E503 hex. RX now checks to see how it is to interpret this data byte. It must first decide if it's ASCII or Baudot. If it's Baudot, we must determine if it is a letter or figure, then convert it to the correct ASCII code. Now we have to determine if it's a control character or a printable character. If it's control, we take the appropriate action, and if not, we pass it to the display module. The display routines print it in the received-text portion of the video screen and, if hard copy is desired, on the printer.

CONTROL (Fig. 9) accepts legal control codes and sets the desired parameters to direct the decisions required of all the other routines. It does this by maintaining a 16-bit status word which is used by the other modules. Each bit of the status word represents a control function's current status. The other modules simply have to examine this status word to decide how they are to perform. All control functions are "toggle type." This means that they can be accessed at any time during program execution since all we have to do is "flip" them. The next time the bit is examined, the proper adjustment in operation is made. I am currently using only 7 of

FSK Demodulator Parts List

1	EXAR 2211 FSK demodulator IC		$ 3.95
1	2N2222 NPN transistor		.17

the 16 available bits. Bit zero is used as a letters/figures flag by the transmit routines. Bit 1 indicates that the buffer mode is engaged. Bit 2 determines line or word mode. Bit 3 activates the Baudot unshift on space feature. Bit 4 is used to control the printer. Bit 5 is the receive/transmit indicator, and bit 6 tells us if we're in ASCII or Baudot mode. In addition, there are control inputs to choose the transmit buffer and to change the baud rate. The last thing CONTROL does before returning to CI is to update the status line at the top of the video monitor. This line always shows the current status of all switches and activities.

The DISPLAY module (Fig. 10) receives characters from the other modules and prints them in the proper location on the video monitor, and on the line printer if so requested. My system uses memory-mapped video so that it was relatively simple to set up the split-screen display. If you use a serial terminal, you will have to write a display module to suit your hardware. My screen is split into four sections. The top line is the status line, as mentioned before. It is displayed in reverse video so that it will stand out. This is followed by a blank line and then 8 lines of receive space. Beneath the receive space is another blank line and then 4 lines that display data as it is being transmitted. The very bottom line is the transmit-buffer input line.

In use, you simply select the operating mode you desire and then have fun. While in receive mode, you can watch text as it comes in and type your response into one of the transmit buffers to send when your turn comes. I have 3 buffers on my system, but more can easily be added. I have one large one (500 bytes) for general text and two smaller ones for specific information such as QTH, rig, etc. The transmit-buffer pointer is circular which means that typing the key to increment the pointer to the next buffer eventually gets you to the one you want. The status line keeps you informed as to which one is active. You can then either fill that buffer or send it as desired. When your turn comes to transmit, you simply type a control T to start sending. You can continue to type text into the buffer at the same time using either line or word mode. Corrections to your text can be made at any time prior to entering the key that causes it to be transferred to the buffer. You will see your transmitted text appear on the video just as it is being sent. All controls are always available to you at any time during operation of the program. This makes for quite convenient operating.

That pretty well covers the 2ICTU and the RTTY software that makes it perform. This was a very rewarding project from both the hardware and software standpoints. The modular approach to both also provides a very flexible system, one which can grow and change as desired. I will be glad to respond to any questions or comments if you will be so kind as to include an SASE.

I think you will find the 2ICTU a very convenient way to try the fascinating world of radioteletype without spending too many of those hard-earned dollars. Even if you are not interested in the 2ICTU, the serial port has many other uses, such as driving printers, modems, and the like. 73. ■

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

SOUTH BEND IN
JAN 5

A hamfest will be held on January 5, 1986, at Century Center, on US 33 North between the St. Joseph Bank Building and the river, downtown South Bend IN. Table space is $1.00 per foot. Talk-in on .52/.52, .99/.39, .93/.33, .69/.09, and 145.29. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616; (219)-233-5307.

WAUKESHA COUNTY WI
JAN 11

The West Allis Radio Amateur Club will sponsor the Midwinter Swapfest on Saturday, January 11, 1986, beginning at 8:00 am, at the Waukesha County Expo Center Forum. Take I-94 to Co. F, south to FT, and west to Expo. Admission is $2.00 in advance and $3.00 at the door. Four-foot tables are $3.00 in advance, $4.00 at the door. For tickets or more information, send an SASE to WARAC Swapfest, PO Box 1072, Milwaukee, WI 53201.

VA STATE FAIRGROUNDS
JAN 12

The Richmond Amateur Telecommunications Society will sponsor the ninth annual Richmond Frostfest on Sunday, January 12, 1986, from 8:30 am to 3:30 pm, at the Virginia State Fairgrounds. Admission is $4.00. Flea-market spaces are $4.00; $8.00 with an 8-foot table. VEC exams will be held on Saturday. For more information, write the Richmond Frostfest, PO Box 1070, Richmond VA 23208, or call Bill Scruggs N4DDM at (804)-272-8206.

OAK PARK MI
JAN 12

The Oak Park ARC will sponsor a radio swap on Sunday, January 12, 1986, from 7:30 am to 4:00 pm, at Oak Park High School, 14300 Oak Park Boulevard, Oak Park MI 48231. For more information, contact David Lefko WB8RGQ, 875 S. Pontiac Trail #103, Walled Lake MI 48088.

HOSARC 13TH
JAN 19

The Hall of Science Amateur Radio Club will operate special-event stations using the call WB2JSM on January 19, 1986, from 1500 to 2100 UTC, to commemorate HOSARC's thirteenth anniversary. SSB operation will be in the first 25 kHz of the 40-, 20-, 15-, and 10-meter General phone bands. CW operation will be in the first 25 kHz of the 80-, 40-, 15-, and 10-meter Novice bands and in the first 5 kHz of the 30-meter band. For a commemorative certificate, QSL with a large SASE (44 cents or 1 IRC) to HOSARC QSL Manager, Arnie Schiffman WB2YXB, 81-22 250th Street, Bellrose NY 11426.

YONKERS NY
JAN 26

The Yonkers Amateur Radio Club will hold an electronics auction on Sunday, January 26, 1986, from 9:00 am to 3:00 pm, at Lemko Hall, 556 Yonkers Avenue, Yonkers NY. Admission is $3.00; children under 8 are free. Inspection is from 9:00 am to 10:00 am and the auction will begin at 10:00 am. Talk-in on 146.865/R, 440.150/R, and 146.52. For more information, contact the YARC, 53 Hayward Avenue, Yonkers NY 10704; (914)-969-1053.

SOUTHFIELD MI
JAN 26

The Southfield High School ARC will hold its 20th annual Swap and Shop on January 26, 1986, from 8:00 am to 3:00 pm, at Southfield High School, 24675 Lahser, Southfield MI. Admission is $2.50. Two 8-foot reserved tables are $20.00. Each additional table is $10.00. For more information, write Robert Younker, Southfield High School, 24875 Lahser, Southfield MI 48034.

TEACHER IN SPACE
JANUARY

The Concord Brasspounders ARC will operate W1OC to commemorate Christa McAuliffe's teacher-in-space flight of the space shuttle. Operation will be from 1300 UTC on Saturday to 1259 UTC Sunday during the first weekend following the launch of the shuttle with Christa aboard. Anticipated launch date is January 22, 1986. Suggested frequencies are: phone—7.285, 14.285, 21.385; CW—7.050, 14.050, 21.050; Novice—7.105. For a certificate, send an SASE to W1OC, PO Box 2214, Concord NH 03301.

BATTLE OF KWAJALEIN AND ROI-NAMUR
FEB 1-10

The Kwajalein Amateur Radio Club will operate special-event station KX6BU from 0600 UTC on February 1, 1986, until 0600 UTC on February 10, 1986, to commemorate the 42nd anniversary of the Battle of Kwajalein and Roi-Namur. Frequencies will be: SSB—28.550, 21.350, and 14.250; CW—28.050, 21.050, 14.050, and 7.025. For $6.00, stations working KX6BU will be issued a certificate, a QSL, and a 64-page book describing the Battle of Kwajalein and Roi-Namur. $3.00 will bring a QSL and a certificate. All requests should be sent to: KX6BU, Box 444, APO San Francisco 96555-008.

PUNXSUTAWNEY PHIL
FEB 2

The Punxsutawney Amateur Radio Club will operate special-event station KA3CUY on Sunday, February 2, 1986, beginning at 9:00 am EST, to commemorate Groundhog Day 1986. Frequencies are 3.950 and 7.230 MHz ± QRM. KA3CUY will carry a recording of the official proclamation for the next 6 weeks' weather (as determined by Punxsutawney Phil). For a certificate, send a QSL and a large SASE to PARC, RD 5, Box 14, Brookville PA 15825.

ST. CATHARINES ONT
FEB 8

The Niagara Peninsula ARC will hold its annual hamfest and flea market on Saturday, February 8, 1986, beginning at 8:00 am, at the UAW Hall, Bunting Road, St. Catharines, Ontario. Talk-in on 147.240/.840. For more information, contact NPARC, Box 692, St. Catharines, Ontario LR2 6Y3, Canada.

MARLBORO MA
FEB 16

The Algonquin ARC will hold its annual hamfest/electronic flea market on Sunday, February 16, 1986, beginning at 10:00 am, in the Marlboro Junior High School cafeteria. Admission is $1.00. Tables are $7.50 in advance and $10.00 at the door. Seller setup begins at 8:30 am. Talk-in on .01/.61 and .52. For reservations or more information, contact the AARC, PO Box 258, Marlboro MA 01752; (617)-393-9920.

SPOONER WI
FEB 16

The Wild Rivers ARC will hold its midwinter swapfest on Sunday, February 16, 1986, from 10:00 am to 3:00 pm, at the Spooner Experimental Farm, east of Spooner WI on Highway 70. Exams will be given. Tables are available. Talk-in on 147.81/.21. For more information, contact Tom Young KD9FC, Route 5, Box 5239, Hayward WI 54843.

MANSFIELD OH
FEB 16

The Mansfield Midwinter Hamfest/Auction will be held on Sunday, February 16, 1986, beginning at 7:00 am, at the Richland County Fairgrounds, Mansfield OH. Admission is $3.00 in advance and $4.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Talk-in on 146.34/.94 (W8WE). For tickets or more information, contact Dean Wrasse KB8MG, 1094 Beal Road, Mansfield OH 44905; (419)-589-2415 after 3:00 pm EST.

FRIDLEY MN
FEB 22

The Robbinsdale ARC will sponsor the fifth annual Midwinter Madness Hobby Electronics Show on February 22, 1986, from 7:00 am to 2:00 pm, at Totino-Grace High School, 1350 Gardena Avenue NE, Fridley MN. Admission is $3.00 in advance and $4.00 at the door. 8-foot tables are $8.00; 1/2 tables are $4.00. Exams will be given. Talk-in on 147.60/.00 (K0LTC) and .52 simplex. For more information or to register, contact the Robbinsdale ARC, PO Box 22613, Robbinsdale MN 55422, or call Bob at (612)-533-7354.

GLASGOW KY
FEB 22

The Glasgow Swapfest will be held on Saturday, February 22, 1986, beginning at 8:00 am, at the Glasgow Flea Market Building, two miles south of Glasgow KY, just off Highway 31E. Admission is $2.00; no extra charge for exhibitors. The first table is free, and each additional table is $3.00. Talk-in on 146.34/.94. For more information, contact Mike Goad N4HCO, Route 4, Box 354, Glasgow KY 42141.

CHICOPEE MA
MAR 2

The Mount Tom Amateur Repeater Association will hold its annual flea market on March 2, 1986, from 8:00 am to 3:00 pm, at the Knights of Columbus Elder Council 69, Granby Road, Chicopee MA. Admission is $1.00; ladies and children under 12 are free. Tables are $7.00 in advance and $8.00 at the door. For more information, contact MTARA, PO Box 3494, Springfield MA 01101.

ST. LOUIS MO
MAR 14

The Jefferson Barracks ARC will sponsor its 26th annual amateur-radio auction on Friday, March 14, 1986, beginning at 7:30 pm, at Concordia Turners Hall, 6432 Gravois, St. Louis MO. For more information, contact the Jefferson Barracks ARC, 1624 Union Road, St. Louis MO 63125.

FORT WALTON BEACH FL
MAR 15-16

The Playground ARC will hold its 16th annual North Florida Ham/Swapfest on Saturday and Sunday, March 15-16, 1986, at the fairgrounds, Fort Walton Beach FL. Admission is $3.00; XYLs and children are free. Tables will be available. Talk-in on 146.19/.79. For more information, contact Hud Huddleston KF4BU, 925 Forest Avenue, Fort Walton Beach FL 32548; (904)-862-2566.

LETTERS

WISE UP

I just read Rick C. Wilson's letter, "I Hate Code" (*73*, March, 1985). I wonder if Rick would hate the code so much if he knew that by passing a few code tests (he says he already knows a lot about electronics) he could command a cushy job on a world-ranging freighter.

I wonder how much he would hate the code if a military conflict should rear its ugly head.

Sure, it's tough to apply your butt to a hard chair and try to copy the stuff when it's dot for dot and dash for dash. Once it gets learned, though, it opens up a whole new world. Get yourself wised up, Mr. Wilson.

Paul L. Schmidt W9HD
Bloomfield IN

STOP HIDING

I love my simplex autopatch. There, I said it and I'm glad. Now that it's out of the closet, let the other hams enjoying this delightful device stop hiding and not feel guilty in its use.

I fully realize that the incorrect use of simplex autopatch (on, say, 2 meters) can lead to an abuse of our privileges, but I feel that the proven maturity of licensed amateur-radio operators will prevail and it will be used properly.

A lot of misunderstanding, traced to cliquish repeater groups who found their uniqueness in offering patches, is now ended. They may feel that this privilege shall only belong to them—how dare an individual try to bypass them!

I'm tired of reading of the restrictions in advertising that the manufacturers of simplex devices must follow, and above all, I dislike the reluctance of the ham fraternity to openly discuss their use.

Answering the phone while driving is as much fun as DXing, contesting, or any other facet of our hobby. Besides, we are only using one frequency versus the repeater using two. With the BSR touchtone™ appliance controller, I can call my phone and have the unit shut off, thus satisfying FCC requirements.

Don't put restrictions on its use. There is enough room in the spectrum for everybody.

Mike Herbstman KM2F
New York NY

RE DISPLAY REPLAY

I cannot help but wonder what Roger Grandbois ("Letters," October, 1985) was trying to prove. Mr. Grandbois, manufacturer of digital display systems, was so determined to belittle the "What You See is Where You're At" frequency-display project (*73*, July, 1985) that he overlooked the more obvious virtues of the project. To me, it seems apparent that the purpose of the project was to provide the experimenter/builder with an inexpensive solution to the problem of display resolution as opposed to the purchase of a more advanced receiver or commercial display adapter. The prescribed project executes this task like a champ. Nevertheless, Mr. Grandbois insists on stating the obvious shortcomings of the project while espousing his own product.

As presented, the July '85 project does exhibit change in sidebands and will only work on single-mix superheterodyne receivers. True, these problems exist. But with the use of moderate circuit additions, the frequency display will find a place in more complicated applications. It is a fair assumption that any experimenter with a reasonable understanding of radio receivers will arrive at the same conclusion. Carl Anderson ("Letters," October, 1985) provided us with a modification of the display's counting direction. This modification furthers the applications of Mr. Miller's project. Undoubtedly, some other ingenious Gus will engineer additions that will beat the aforementioned technical problems.

I was inspired and taught by radio amateurs of the "old school." That is the practice of construction and experimentation. Mr. Miller provided a fine construction article of a very practical project. My fellow radio builders will agree.

Mark Foltarz KA4JVY
Tampa FL

Mark—Good news! Thomas Miller has designed a "universal" version of his display. Look for it in an upcoming issue of 73.—KW1O.

MORE! MORE!

I was fascinated by Victor Layton's article, "Above Intercept," in the October, 1985, issue. I was a flight-control officer at Watton during the time the event took place.

The 25th Bomber Group was a most unusual group in the 8th Air Force. Besides the undercover work that Layton wrote about, we also helped to perfect blind-bombing techniques, LORAN, and Mickey. We did photo and weather reconnaissance and were pathfinders for bomber missions. If there was anything secretive to be done, I'm sure we did it. (As a small point of digression, I should state that President Roosevelt's son, Elliott, was our commanding officer.)

I wrote to Mr. Layton and sent him a lot of history and information about the 25th Bomber Group at Watton, and he sent back a nice reply. I'm sure he could tell many more exciting stories. "Above Intercept" was a departure from the usual technical articles and brought back a feeling of nostalgia. More! More!

William Bernstein KA2OVR
Great Neck NY

FULL ADVANTAGE

If we are to attract new people to amateur radio, we need to be able to demonstrate that we know how to use the privileges that we have to our full advantage. One improvement that would benefit the beginner would be to establish a national CW calling frequency in the middle of the 10-meter Novice band, 28.150 MHz.

Henry J. Hampel KA0TUP
St. Louis MO

TO K7UGA:

Dear Senator Goldwater:

I share your concerns over the declining (and aging) amateur-radio population, and I agree with your proposed alternatives to a no-code license; these proposals are echoed almost everywhere in the ham literature.

What bothers me is that two critical points have not yet (to my knowledge) been addressed. Without careful consideration of these points, we may be solving the *wrong* problem, and we may be doing irreparable harm to amateur radio as a result.

1. I keep hearing that the average age of a licensed amateur-radio operator is near 46, and that it is increasing more than one year, each year.

Averages, by themselves, can be very misleading. I have never seen a standard deviation, nor have I seen a comparison to a population of non-hams with the same sexual, geographic, and economc distributions. I'm not a statistician, but would these data show us that hams are actually increasing their population relative to the one above? Would these data perhaps illuminate the reasons for decline? Why am I the only ham asking these questions?

2. The problem is not limited to amateur radio: Robert Burnham said (see "Forum," September, 1985, *Astronomy Magazine*), "If we don't get the children interested in astronomy, there'll be no next generation of astronomers." Within the last six months, *Live Steam Magazine* (a voice of model steam-engine enthusiasts) published bar charts and graphs based on profiles of club members' records from around the country. The projections (don't let the oily fingernails fool you; their presentation was the best I've seen) clearly showed that they were in a dying hobby if something wasn't done about it, and pretty soon.

I am writing to you, Senator, and sending copies to every major amateur-radio publication because I want my concerns to be considered by a majority of hams *before* we make changes to our hobby.

I believe we may make a hasty, disastrous change to amateur radio unless we examine *our* problem more closely, and examine *the* problem more carefully.

Alex Vrenios KX9I

Middle Village NY 11379

SATELLITES REVISITED

I'm reluctant to admit this, but I think that I'm becoming something of an audio voyeur. In a way, I think most hams are. After all, shortwave listening is nothing more than audio voyeurism, and "copying the mail," be it on a repeater or on the HF bands, falls into the same general category.

But I believe I've probably taken audio voyeurism to its ultimate limit. As regular "Fun!" readers know, a few months ago I acquired a satellite-TV system. After a few weeks of watching Peruvian-rules football, music videos in Esperanto, and Dr. Gene Scott, I began to yearn for something a bit more esoteric. It was at that point that I discovered the world of SSB on C-band satellites.

A friend told me that if I hooked a good-quality communications receiver, like my Kenwood R-100, to the baseband output of my satellite receiver, I could pick up all sorts of interesting signals transmitted on SSB. The sort of signals, my friend claimed, that are far more interesting than the exploits to be found each evening on F4, 12. Better yet, he said, each transponder offers 36 MHz of frequency space. Yes, friends, 36 MHz on some 16 satellites, each with approximately 24 transponders. That's equivalent to 384 HF spectrums!

This is where my audio voyeurism comes in. As you probably know, most long-distance telephone calls are transmitted by satellite these days. What you may not know, however, is that many of the satellites used are the same ones that home satellite installations receive. Therefore, a satellite earth station connected to an SSB receiver results in a lot of interesting listening.

The Communications Act of 1934, as amended, prohibits listeners from divulging the contents of telephone communications. However, if you happpen to accidentally tune across these signals, as I often do, and you happen to hear some really juicy conversations, as I often do, there isn't very much the FCC can do about it. After all, as a radio amateur, I have a definite need to tune across the complete spectrum of most satellite transponders, and if in the course of my technical explorations I happen to hear some heavy breathing going on, it isn't my fault. Let MCI, AT&T, and the others scramble their transmissions, I'm going to continue my experimentation. I'll keep quiet, but I'll keep listening.

So there you have it. Audio voyeurism taken to its limit. As for me, I'm just waiting for Picturephone to make its grand return (heh-heh).

ELEMENT 1 MULTIPLE CHOICE

1) How wide is a standard US baseband video signal?
   1) 4.0 MHz
   2) 4.2 MHz
   3) 14 MHz
   4) 40 MHz

2) Satellite receivers typically use GaAsFET transistors. The acronym GaAsFET stands for:
   1) Gallium Arsenide Field Effect Transistor
   2) Gallic Arsenic Field Effect Transistor
   3) Germanium Arsenide Field Effect Transistor
   4) Gas Arsenic Field Effect Transistor

3) In a satellite receiver, a phase-locked-loop (PLL) circuit is often used as:
   1) a video enhancement circuit
   2) a low-noise amplifier
   3) a composite video generator
   4) an FM demodulator

4) DOMSATs:
   1) are operated by AT&T
   2) are operated by RCA
   3) are operated by COMSAT
   4) is a generic term for domestic satellites

5) Name the *73* Magazine columnist who founded his own national TV system on the Turks and Calcos Islands.
   1) Bill Gosney
   2) Chod Harris
   3) Robert Baker
   4) Bob Cooper

ELEMENT 2
TRUE-FALSE

	True	False
1) A satellite's "footprint" refers to its signal strength at various points on the earth's surface.	____	____
2) The "look angle" is the angle above the horizon at which a satellite signal arrives at an earth station's location.	____	____
3) Geosynchronous satellites are immobile.	____	____
4) "Shrouding" is a synonym for "dish."	____	____
5) "Sky noise" is a type of man-made interference.	____	____
6) "Adaptive deviation multiplex" is a satellite video format.	____	____
7) Teletext and videotex are usually transmitted on the vertical blanking interval (VBI) of a satellite-TV signal.	____	____
8) US satellites can only transmit NTSC video.	____	____
9) In microwave reception the term "TI" usually stands for "terminated interconnect."	____	____
10) Dishes roughly two meters in diameter are routinely used for video reception.	____	____

ELEMENT 3
SCRAMBLED WORDS

Unscramble these words relating to satellites:

POMRCAATRO	RRRBUSCAIE
HOFNEERD	RATSLET
PACES	KAIN
ROCAS	BRITO
OORRT	RETDOWNNREVOC

ELEMENT 4
FILL IN THE BLANK

1) "Sun outages" occur _____ a year.
2) Small dishes have a _____ beamwidth.
3) Large dishes have a _____ beamwidth.
4) The driven element in a microwave antenna can also be called a _____.
5) One uses a _____ to convert a satellite's microwave signal to a VHF frequency.

THE ANSWERS

Element 1:
1—2, 2—1, 3—4, 4—4, 5—4.

Element 2:
1—True If you're outside of the footprint, you can't receive the satellite's signal.
2—True And where you point your antenna.
3—False They move at 7,000 miles per hour, the same rate at which the earth rotates.
4—False Walls or screens around a dish that prevent side interference.
5—False Microwave radiation that comes from deep space.
6—False It's a method used for transmitting stereo audio signals.
7—True It's those little white dots you see on the black line between the picture frames.
8—False They can also handle PAL, SECAM, and the rest.
9—False Terrestrial interference.
10—False Usually for data or audio reception.

Element 3:
(Reading from left to right): COMPARATOR, SUBCARRIER, FEEDHORN, TELSTAR, SPACE, ANIK, OSCAR, ORBIT, ROTOR, DOWNCONVERTER.

Element 4:
1—twice
2—wide
3—narrow
4—probe
5—downconverter

SCORING

Element 1:
Five points for each correct answer.
Element 2:
Two and one-half points for each correct answer.
Element 3:
Two and one-half points for each correct answer.
Element 4:
Two and one-half points for each correct answer.

How did you do?
1-20 points— Beyond the horizon
21-40 points— Suffering from a sun outage
41-60 points— Minimal reception
61-80 points— Some sparklies
81-100 points— Closed-circuit copy

73 AWARDS

Bill Gosney KE7C
2665 North Busby Road
Oak Harbor WA 98277

It's hard to believe the years which have passed since our initial announcement of the famous *73* Awards Program portfolio. Since its introduction by yours truly, KE7C, in 1979, we've seen the program grow to become one of the most sought-after challenges facing amateurs today!

Consisting of six domestic and five DX operating achievements, the program has captured the interest of rag-chewers, DXers, and contesters alike.

The requirements for each award are not as easy as one might first imagine. Once you qualify for an award, you know for sure you've earned it. Here are the five DX awards:

DX COUNTRY CLUB AWARD

1. Available to licensed amateurs and SWL stations worldwide.

2. To be valid, all claimed contacts must be made in a single calendar year (January 1 through December 31), beginning January 1, 1979.

3. This award is issued for phone, CW, and mixed-mode. Should the applicant wish to recognize a single-band or mixed-band accomplishment, he must state his preference when making application.

4. A minimum of 73 DX countries must be worked and confirmed from the *73* Magazine WTW (Work the World) DX Listing.

5. Annual endorsement stickers are available for each succeeding year in which application is made and a minimum of 73 DX countries are worked.

6. To apply, prepare a list of claimed contacts in prefix order. Include each station's callsign, date and time of contact in UTC, mode, and band of operation.

7. *Do not send QSL cards.* Have your list of contacts verified by two amateurs or a notary public.

8. Award fee is $5.00 for each award. Do not send IRCs or foreign currency. Endorsements are granted for a fee of $2.50. Checks on foreign banks must be payable in US funds.

9. Forward your application and fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

DX CAPITALS OF THE WORLD

1. This award is made available to licensed amateurs and SWL stations throughout the world.

2. All claimed contacts must be made on or after January 1, 1979. There are no band or mode restrictions. Special recognition will be given for single band or mode if requested at the time application is made.

3. To qualify, applicants must work and confirm a minimum of 50 different national capital cities in the world. Only capital cities of those countries appearing on the WTW DX listing qualify. Should a country be contacted and its capital city not commonly be known, go ahead and list it in your application. The awards editor reserves the right to make a final determination.

4. To apply, make a list of contacts in prefix order. Indicate the station callsign, date and time in UTC, band and mode of operation, the name of the national capital city, and the DX country.

5. *Do not send QSL cards.* Have your list of contacts verified by two amateurs or a notary public.

6. Award fee is $5.00 and must be payable in US funds. IRCs or foreign currency can no longer be accepted.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

TEN-METER DX DECADE AWARD

1. The 10-Meter DX Decade Award is made available to licensed amateurs and SWL stations worldwide.

2. All contacts must be made on the 10-meter band using only low-power (20 Watts of output or less) equipment. External amplifiers may not be used.

3. To be eligible, all contacts must be made on or after October 1, 1978. Contacts may be made on AM, SSB, CW, or 10-meter FM. Mixed-mode contacts may also be claimed. Crossmode contacts do not qualify.

4. To qualify, a minimum of ten DX countries must be worked from the WTW DX Listing. Endorsements will be given for 25, 50, 75, and 100 confirmed countries.

5. To apply, prepare a list of claimed contacts in prefix order. include the callsign of each station worked, the date and time in UTC, band, mode, and a brief description of the equipment used in making each contact.

6. *Do not send QSL cards.* Have your application verified by two amateurs or a notary public.

7. Award fee is $5.00 in US funds only. Sorry, we cannot accept IRCs or foreign currency. Endorsements are $2.50 each.

8. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD (CLASS A-1)

1. This is made available to licensed amateurs and SWL stations throughout the world.

2. To be eligible, all contacts must be made on or after January 1, 1979. Only communications via SSTV, RTTY, EME (Earth-Moon-Earth), and/or OSCAR will be recognized for award credit. Contacts between stations on OSCAR and EME may be made using the mode authorized in your country. Mixed-mode contacts are not valid, however.

3. To qualify, applicants must work a minimum of ten DX countries from the WTW DX Countries Listing. Special recognition will be made for those exceeding the ten-country minimum.

4. To apply, prepare a list of claimed contacts in callsign prefix order. Include the date and time in UTC, the band and mode of operation, and a description of your equipment and antenna system used to make the contacts.

5. *Do not send QSL cards.* Have your list of contacts verified by two amateurs or a notary public.

6. The award fee is $5.00 in US funds only. IRCs or foreign currency is not acceptable. Foreign checks must be payable in US funds.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD (CLASS A)

1. Available to licensed amateurs and SWL stations throughout the world, this award requires all contacts be made on or after January 1, 1979.

2. Only communications via SSTV, RTTY, EME (Earth-Moon-Earth), and/or OSCAR satellite will be recognized for this award. Contacts between stations on OSCAR and EME may be made using any authorized mode allowed in your country. Mixed-mode contacts are not valid.

3. To qualify, applicants must work and confirm contact with each of the 50 US states. There are no band requirements. Specific band accomplishments will be recognized, however, if requested at the time application is made.

4. To apply, the applicant must prepare a list of claimed contacts in alphabetical order by state. Include the date and time in UTC, the band and mode of operation, and a description of the equipment and antenna system used.

5. *Do not send QSL cards.* Have your list verified by two amateurs or a notary public.

6. Award fee is $5.00 in US funds only. Sorry, we cannot accept IRCs or foreign currency.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Man-

WORK THE WORLD DX AWARD

To enhance the enjoyment of working DX, the editors of *73* take special pleasure in introducing the most complex and probably one of the most sought-after DX awards available today—the Work the World DX Award.

1. The WTW Award is available to licensed amateurs and SWL stations worldwide.

2. To be valid, all contacts must be made on or after January 1, 1979. There are no band or mode restrictions. Special single-band or -mode achievements may be recognized if you make your request the same time application is made.

3. The Work the World program consists of six individual continental awards (North American, South American, European, Oceanic, Asian, and African), each of which is a worthy single accomplishment by itself. To be eligible for the 7th and ultimate award (the WTW Award), applicants first earn the continental recognition. Once all six awards have been applied for, the WTW award will be issued at no charge to the applicant. The operator who earns WTW recognition has truly "worked the world."

4. Requirements for the individual continental awards: North American Award—a minimum of 13 North American countries; South American Award—12 South American Countries minimum; European Award—a minimum of 12 European countries; African Award—12 African countries minimum; Asian Award—12 Asian countries minimum; Oceanic Award—a minimum of 12 Oceanic countries.

5. To apply, prepare a list of claimed contacts for each continent. List contacts in prefix order. Include the date and time in UTC and the band and mode of operation.

6. If you are submitting your sixth continental award, please alert the award manager to this fact.

7. *Do not send QSL cards.* Have your list of contacts verified by two amateurs or a notary public.

8. Each continental award is $5.00 in US funds only. We are sorry, but we can no longer accept IRCs, or foreign currency. Checks written on foreign banks must be payable in US funds.

9. Forward your application(s) and fee(s) to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

Now here are the six domestic awards also being sought after by award seekers throughout the world. These awards are not meant to be an overnight venture and they were designed to not duplicate any in existence today. Each offers its own degree of difficulty and creates a sense of accomplishment.

ANNUAL WORKED ALL USA AWARD

1. If you're looking for a stateside award with a challenge, the USA Award is definitely the one. The annual Worked All USA Award is available to licensed amateurs and SWL stations throughout the world.

2. To qualify, applicants must work each of the 50 US states within the same calendar year (January 1 through December 31). Annual endorsements will be awarded each subsequent year to applicants who verify their claim.

3. All valid contacts must be made on or after January 1, 1979. There is an award for single-band accomplishments on 2, 6, 10, 15, 20, 30, 40, 75, and 160 meters. A mixed-band award is also available.

4. To apply, prepare a list of claimed contacts in alphabetical order by state. List the state, the callsign of the station worked, the date and time in UTC, and the band and mode of operation.

5. *Do not send QSL cards.* Have your list of contacts verified by two amateurs or by a notary public.

6. The fee for this award is $5.00 in US funds. Annual endorsements are $2.50. We are sorry but we can no longer accept IRCs or foreign currency. Checks written on foreign banks must be payable in US funds only.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

THE Q-5 AWARD OF EXCELLENCE

If you frequent the American Novice bands, you will be pleased to learn of this award. This award is not meant to be an overnight accomplishment. Stations meeting the challenge of this award will be proud to display it in their shacks. It depicts the excellence and superiority of a station's transmitted signal as it is heard throughout the various US call districts.

1. The Q-5 Award is available to licensed amateurs and SWL stations throughout the world.

2. To qualify, applicants must work all ten US call districts and receive no less than a Q-5 readability report. A valid RST might be 599, 579, 549, etc., while an RST of 459, 449, or 469 would not qualify.

3. To be valid, all contacts must be made operating CW on those frequencies assigned the American Novice. Contacts must be made on or after January 1, 1979.

4. There are no band restrictions; however, applicants may request special band endorsement at the time application is made.

5. To apply, prepare a list of claimed contacts, logging each one in order of US call district worked. Include the station callsign, date and time in UTC, the frequency, and most importantly, the RST as noted on the confirmation card.

6. *Do not send QSL cards.* Have your list verified by two amateurs or a notary public.

7. Award fee is $5.00 in US funds. No IRCs or foreign currency. Checks written on foreign banks must be payable in US funds.

8. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

DISTRICT ENDURANCE AWARD

If any of you feel our awards are too easy for you, take a hard look at this award! Looks simple, huh? Don't be deceived. Try pursuing it; it will drive you right up the wall with frustration.

For the District Endurance Award, you'll need to find yourself an accurate timepiece, as you'll have exactly 60 minutes to work all ten US call districts. If you surpass the time limit, you'll have to start all over again. It definitely takes some planning; perhaps even some band changing.

Oh, one last important point. All contacts must be made independent of nets and net-type operations and must not be made while a contest is underway! Any takers?

1. The District Endurance Award is available to licensed amateurs and SWL stations worldwide.

2. To be valid, all contacts must be made on or after January 1, 1979. There will be no band or mode restrictions. If you are fortunate to work all contacts on a single band, however, we will be happy to recognize that feat if you mention it at the time application is made.

3. To qualify, applicants must work all ten US call districts in one hour or less. The time will commence the moment the first contact is established (callsign and RST is exchanged) and ends the moment the 10th call-district contact is made. Call districts can be worked in any order so long as all ten districts are worked within the 60-minute period.

4. To apply, applicants must state in their applications that all contacts were made independent of net or contest operation. Applicants must prepare a list of claimed contacts in callsign order by district. Include the date and time in UTC, the band and mode of operation, and the state.

5. *Do not send QSL cards.* Have your claimed list of contacts verified by two amateurs or a notary public.

6. Award fee is $5.00 and must be payable in US funds. No IRCs or foreign currency. Checks written on foreign banks must be payable in US funds only.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

TEN-METER 10-40 AWARD

What would an awards program be without a stateside QRP incentive? Designed especially for owners of converted CB equipment, the 10-40 Award is probably the roughest worked-all-states award in existence. If you don't believe it, ask those who've tried numerous times and failed.

1. This award is available to licensed amateurs and SWL stations throughout the world.

2. To be valid, all contacts must be made on the ten-meter band using low power (20 Watts of output or less.) External amplifiers are prohibited. Contacts must be made on or after October 1, 1978, on AM, SSB, CW, or FM. Crossmode contacts will not count.

3. To qualify, applicants must work and confirm at least 40 US states.

4. To apply, make a list of contacts made in alphabetical order by US state beginning with Alabama. Include the call of the station worked, the date and time in UTC, the mode of operation, and a brief description of the equipment and antenna system utilized to make the contacts.

5. *Do not send QSL cards.* Have your list verified by two amateurs or a notary public.

6. Award fee is $5.00 in US funds. IRCs and foreign currency are not acceptable. Checks written on foreign banks must be in US funds only.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

CENTURY CITIES AWARD

Designed as a dual worked-all-states effort, *73* presents the Century Cities Award. The applicant who has earned this recognition has accomplished probably the greatest feat available in WAS award programs.

1. Sponsored by *73* Magazine, this award is available to licensed amateurs and SWL stations throughout the world.

2. All contacts must be made on or after January 1, 1979, to be valid.

3. To qualify, the applicant must work and confirm a minimum of two cities or towns in each of the 50 US states, for a total of 100.

4. To apply, prepare a list of contacts in alphabetical order *by state.* Include the callsign, the date and time of the contact in UTC, the band, and the city.

5. *Do not send QSL cards.* Have your claimed contact list verified by two amateurs or a notary public.

6. Award fee is $5.00 in US funds. Do not send IRCs or foreign currency, as they are no longer acceptable. Checks written on foreign banks must be payable in US funds.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277.

How does *73* process award applications? Upon receipt of an application, each entry is carefully scrutinized for authenticity. They must be sent to the Awards Manager in the proper format as noted in the award rules.

If your application is approved, a worksheet is prepared. A copy is sent to *73* headquarters to process your certificate. There your award is given a personal touch and later mailed to your door. A copy of the worksheet is also mailed to the applicant to acknowledge receipt of the application.

Should an applicant feel it is necessary to follow up an application, send your inquiry to *73* Magazine, c/o Carole Macioci, 80 Pine Street, Peterborough NH 03458. Always enclose a stamped business-size envelope with your letter.

We hope you enjoy the challenges of the *73* awards program. We ask that you share it with your amateur friends.

REVIEW

YAESU FT-209RH HANDIE-TALKIE

I needed a new 2-meter radio. My trusty Kenwood TR-7730 had been sold a year ago to help pay for a new car, and I had since saved up enough money to get back into VHF. But I needed something different. A full-featured radio with scanning, *memories*, DTMF pad, and the like was preferred.

Since I also travel by air a lot, I wanted a radio I could run around with without having to lug around a rig and big power supply. Also, having been bit by the packet bug, I needed a way to monitor the local digipeater (only fair since it had my call on it).

The obvious solution seemed to be one of the new generation of moderate-power (5 Watts), computer-controlled handie-talkies. *You know the kind I'm talking* about—the ones with the fancy keyboards and the digital ashtrays. I never really had a very high opinion of these units. To me, an HT was supposed to be a basic transceiver with a few crystal-controlled channels (or a thumbwheel-selected synthesizer) to be used as a status symbol at swapfests or for monitoring a few frequencies. These new units struck me as, well, wimpy. I also remember the terrible reliability problems these units had when

they first hit the market a few years back. Now they had to be considered.

As I started my search for a full-featured HT at one of the recent area ham conventions, I found I had more than enough reason to be skeptical. Looking down the aisles of the exhibitors' hall, I saw most of the wearers of one brand looking like Leaning Towers of Pisa because the units were so heavy on their belts. Another rig had some nice features but ran on a screwy voltage: An adaptor had to be purchased to run the thing off 12 V. Still another HT looked great and was the next model up from a very popular basic HT, but the only place I saw them was at the exhibitors' table because none of the distributors could get them imported!

Then I ambled over to the Yaesu booth and saw their FT-209RH.

Inside the Box

Your hard-earned cash buys you the radio, a soft case, a rubber ducky antenna, a standard-size battery pack, and a wall charger as standard equipment. Major options include a speaker/mike, headset/mike, several styles of charger/dc-supply combinations, battery packs (including one that holds six AA-size dry cells), and a tone-squelch (i.e., PL™) encoder/decoder. I decided to get a speaker/mike and a couple of extra battery packs with my unit. All told, I spent a shade under $400 for the package.

Physically, the business end of the FT-209RH (*sans* battery pack) is almost exactly the same size as the ICOM 2A/AT without its battery pack (I use the 2AT for comparison here because they are so common—almost everyone has at least seen one). With a standard-size battery pack on both units, the Yaesu is maybe a half inch taller. Weight is also close, the Yaesu, with the standard battery pack, being heavier by a small, but noticeable margin. The two units are virtually identical in size and weight when using a smaller battery pack on the 209. The 209 is also noticeably thinner and lighter when compared to its older brother, the FT-208.

The rubber ducky is ordinary, with a BNC connector. The carrying case is a rather flimsy plastic affair. It covers the 209's display with clear plastic but leaves the keyboard "out in the open" with a cut-out section. And it fits worse than a Joliet Special.

Batteries

The standard battery pack runs 12 V and is rated at 500 mAh, producing 5 W from the transmitter. An available smaller NiCd pack runs 10.8 V at 425 mAh and reduces the transmitter's output to about 3.5 W. The dry-cell pack reduces transmitter power to about 2.5 W.

The battery charger that comes with the 209 is a small wall transformer type. It's a trickle charger, taking about 15 hours to charge the standard NiCd pack fully. It *cannot* be used to charge the smaller pack; a separate charger is required. Yaesu offers a drop-in charger that will charge either NiCd pack in under 1.5 hours (then maintain the charge on trickle) and simultaneously operate as a dc supply.

The NiCd packs themselves have two small sockets (of different types so they can't be connected incorrectly) and four metal plates on the bottom. One socket is for dc (the HT will accept 6-15 V dc) direct to the radio. A circuit in the battery pack regulates the proper voltage to the HT. The other socket is for battery charging. The small plates on the bottom of the pack are used with the drop-in charger. The dry-cell pack is just a simple holding case. There are no connections underneath, therefore it is not possible to run a 12-V-dc supply through it like the NiCds.

Receiver

This is a pretty hot little receiver for a handie-talkie. Less than .1 uV was enough to break the squelch with an intelligible signal. Sensitivity was measured at .18 uV for 12 dB Sinad, 1 uV for 30 dB S + S/N.

Unfortunately, the good sensitivity seems to have lowered the 209's immunity to intermod somewhat. Subjectively, the unit seems to be more susceptible than other HTs, especially when connected to a base-station antenna.

Selectivity came in at −6 dB for ± 7.5 kHz and −60 dB for ± 15 kHz.

Transmitter

The transmitter section will produce a good solid 5 Watts on high power with the 500-mAh (12-V) battery. A 13.8-V-dc supply will squeeze out a bit more. The manual says the low-power mode will run 500 mW, but my unit runs 700 mW. Low power output is adjustable, but a maintenance manual is pretty much required to find the spot.

The transmiter output is also very clean. Spurious transmissions are down over 70 dB and the second harmonic is −60 dB from the carrier frequency. Tested with a 1000-Hz tone, deviation runs a little over 4.7 kHz. Touchtones™ from the keyboard deviate about 3.3 kHz, just right for most repeater autopatches.

I had quite a scare while making the second-harmonic measurement mentioned above. The spectrum analyzer used for making the measurement showed the display shown in Photo B. It appeared that the second harmonic was only 30 dB below the carrier frequency. Hardly a sparkling specification! I called for a "second opinion." Sure enough, the second device showed a very respectable −60 dB. Turns out a notch filter was needed with the original analyzer. A lesson to be learned for all those making test measurements!

Functions

Make no mistake, the FT-209RH can do a lot of things. Ten memories. Priority channel. Calling channel. Programmable tone squelch (with the tone option). A *zillion* scanning modes. In fact, there are so many functions that it can take a while to learn all the commands! Even Yaesu doesn't know everything it can do: They concede the point in the last paragraph in the owner's manual.

There are controls on literally every side of the 209, including behind and even underneath! The top of the unit holds the usual volume and squelch controls, high/low power switch, sockets for external mike and speaker, and VOX controls (used with the optional headset/mike). Two minor gripes: There are no plugs to seal the mike and speaker sockets when not used, and the VOX switches are "active," even when there is no VOX headset/mike connected. Accidentally activating the VOX switch will cause a VOX-delayed end of transmission after releasing the PTT switch (neither the internal mike nor the optional speaker/mike will operate in a VOX mode).

A master reset button is located in a tiny recessed hole on the back of the HT. Pushing a small pointed object like a pin into the hole while the 209 is turned on will reset the radio's functions. This is the "boy, I really screwed something up" button.

Another small button *underneath* the radio sets the smallest scan step. The battery pack must be removed for access and, like the reset button, a small pointed object must be inserted.

The PTT button is located on the left side of the radio. A momentary-contact lamp button on the right side illuminates the LCD display and signal-strength meter for viewing in low-light conditions.

Front Keyboard

There are three main uses for the keyboard: to transmit DTMF tones, to enter frequencies, and to access HT functions. All the keys except the F (Function) key have two functions.

While the 209 is transmitting, the keyboard will act as a 16-digit DTMF encoder. The usual numbers * and # are marked on the keyboard. The auxiliary tones are accessed with the I (down arrow), M, D, and F buttons.

The keyboard is used for entering frequencies, either for direct selection or for loading into memory. Frequencies are entered from the lowest MHz on down, terminated by hitting the D (for dial) button. For example, entering 6025D would set the frequency to 146.025 MHz. All four digits need not be entered: Pressing 65D will set the HT to 146.500 MHz. Note that nothing happens until that D button is pushed. The next logical step in frequency selection is entering an offset if a repeater will be used. Selecting an offset (+ or −) will shift the transmitter 600 kHz, or any other desired offset selected with the Shift (Function then Reverse keys) function. The Reverse key allows monitoring of a repeater input or "upside-down" operating. The selected offset will remain even if the dial frequency is changed.

The selected frequency and offset (and even a selected subaudible tone frequency with the optional tone module) may be placed into one of the ten memory channels by pressing the desired channel number (0–9) followed by the M key. Memory frequencies are recalled by pressing the channel number followed by the MR key. Memory channel 0 may be recalled instantly with just the * key. Yaesu suggests this channel be set to a calling frequency.

There may be more ways to scan frequencies with an FT-209RH than you can possibly use. The entire band may be scanned. The memories may be scanned. The band between two memory channels may be scanned. You can manually scan. There is auto stop on busy channels (with auto resume), and auto stop on clear channels (with auto resume). You can operate on a dial frequency while monitoring a memory channel or mask memory channels so they won't be scanned at all. Sheesh! Scanning is initiated using the up- and down-arrow keys (↑ and ↓), with the type of scanning (manual, stop-on-clear, or stop-on-busy) selected with a small slide switch on the lower edge of the keyboard, and the mode of scanning depending on whether a dial frequency or memory channel is currently displayed.

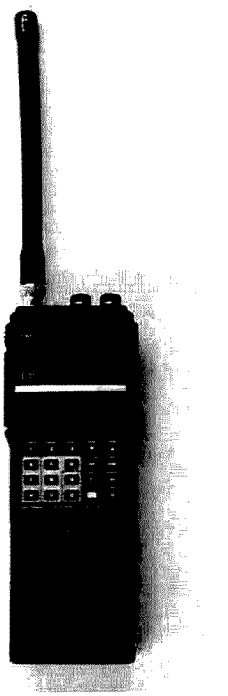

Photo A. Yaesu's FT-209RH.

There are several controls that are intended for the operator rather than the radio (or at least aren't related to either of the two topics above). Slide switches control the function of the signal/battery-level indicator and a keyboard lockout. A "beep" on keypress may be turned on or off. But by far the mode that really makes me want to jump up and down and shout "oh boy, this is great!" is the battery-save feature. When the 209 is in the save mode,

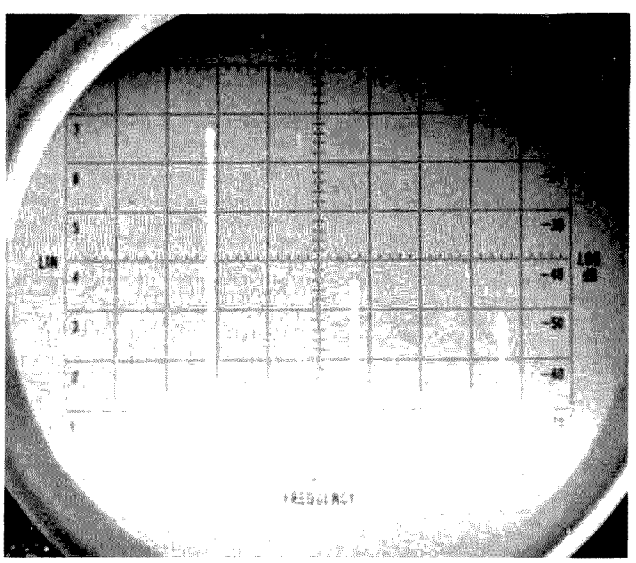

Photo B. What's wrong with this display?

the HT will shut off the receiver circuits and almost everything else except some timers and related stuff for a front-panel-selected amount of time, up to three seconds. It will then reactivate for 300 ms to see if there is receiver activity. If not, it goes "back to sleep" for another cycle. If there is activity, the mode will stand by until the channel is quiet for at least five seconds, when it will start again. Current drain in the save mode is a miniscule 6 mA! Given a 500-mAh battery, it is possible to monitor for several *days* without changing batteries.

Unfortunately, the save mode will not work during scanning, although it is possible to effectively monitor two frequencies in the save mode by using the radio's "priority channel" function. The function switches the receiver from a dial frequency to a selected memory channel for 300 ms every 5 seconds under normal conditions. In the save mode the frequency will alternate between the dial frequency and the memory channel every time the receiver "wakes up."

Some Final Thoughts

It takes a while to memorize all of the commands available to someone using an FT-209RH. For me, the learning curve was much longer for the 209 than for other radios I have used. Some of the commands may be unnecessarily complex. I think Yaesu could have made the 209 much more user-friendly. For example, the VOX functions could have been put in a less prominent place than the top of the unit. A PTT button lock would have been nice, too.

I've touched only the major functions of the FT-209RH. I could probably go on for another couple of pages if I were to describe all the possible permutations. Suffice it to say that during normal operation, very little extra work is required. Once everything is set, there's not much reason to change anything. And judging from on-the-air reports, this HT "sounds good."

I did run into a problem which could only be attributed to a lapse in quality control. The transmitter would mysteriously cut out if the HT was held a certain way or if it was shook. Opening the unit (not for the faint of heart), I found the cause to be a wire not properly soldered to the antenna connector's center conductor. To be fair to Yaesu, I should point out that the times I needed to speak to someone at their Ohio Service Center I was treated promptly and politely.

All that said, I still really like the FT-209RH. After all the commands are mastered, it is a very versatile, powerful unit. It can do everything a base-station rig can do, and then some. The memories and some of the memory-scan functions are particularly useful. The battery-save feature is something that should be in every HT...I'm spoiled now. Borrow somebody's Yaesu FT-209RH for a few days and take it for a test run. But be sure to ask for the owner's manual, too.

I'd like to thank Steve KE5O, Paul WA5JMZ, and Chris WB5ITT for their comments, suggestions, and help in the preparation of this review.

HORSE SENSE SYSTEM DESIGN SOFTWARE

I recently had an opportunity to evaluate "Radio System Design Calculations" and "Radio Interference Analysis," two new software packages from Gerald Townsend at Horse Sense Software. Both are available for several microcomputers and both cost about $35.00, depending upon your particular configuration. I tried them out on an IBM PCjr with an RGB monitor and an Okidata Microline 93 printer.

Radio System Design Calculations

This package is a collection of conversion programs and calculations designed to save wear and tear on your pencil. Five major categories may be selected from a main menu (see Fig. 1), and each category consists of one to six subprograms. All of the programs are menu-driven and I found the instructions to be clear and presented in a logical order (a big shortcoming for many programs of this type!).

I felt that only three of the five programs in the main group were useful—Frequency/Wavelength Conversions, System Received Signal Levels, and Propagation Calculations. Of the remaining two categories, Gain of Parabolic Antennas is the most trivial. Simple formulae like the one for parabolic gain are best evaluated by hand or on a scientific calculator, not by a program running on an $800 computer. Microvolts/dBm Conversions, my other pan, just wasn't useful in my application; the program is quite handy if you need to change dBm to microvolts into various impedances.

Normally, I would have included Frequency/Wavelength Conversions on my list of trivia, but after a few test runs I was convinced of its utility. It's a simple matter to use the familiar 492/frequency to get the half wavelength of a dipole in free space, but this routine gives you *everything* you need to know, including the half and quarter wavelengths for two common coaxial cables, and it does it much faster than a calculator.

Propagation Calculations and System Received Signal Levels are the other two winners in the package. The first will grind out facts about any radio site you can devise, including path loss between sites, distance to real and radio horizons, and required antenna heights for a given horizon. Combine these parameters with the Signal Levels program (which produces a microvolts-at-the-receiver value for a given receiver and signal path) to get the answer to questions like, "How will raising my repeater's antenna by ten feet affect the repeater's performance?" and, "What coverage will a new repeater site give?" It seemed a *bit tedious* hopping back and forth between programs, but it actually took only a second or less.

Radio Interference Analysis

This software design tool was designed specifically for the land-mobile site planner and is not as practical for amateur use as "Radio Systems Design Calculations." It consists of two modules, one for intermodulation analysis and the other for image-response analysis. The two modules share a common database which contains transmitter/receiver information for a particular site (such as an amateur repeater installation which coexists with commercial users). Site files are built and saved in a simple step-by-step fashion, and there are ample opportunities to review and revise your entries.

The Intermodulation analysis program uses a two-pass process for either 3rd- or 5th-order products. The first pass considers two transmitters operating at the same time and the second looks at three transmitters. In both instances *all of the* products produced by the hypothetical mixing of the transmitted frequencies are checked against each receiver's frequency. Products which fall within a specified receiver susceptibility range (the default is 30 kHz) are flagged and sent to the printer. Fig. 2 is a sample 5th-order three-transmitter printout which was generated by a site file included on the program diskette. The number-crunching took about four minutes and the program executed about 135,000 calculations.

The image-response section compares all of the transmitters in the site file against a receiver with a user-specified receive and I-f frequency. Again, problems are flagged and sent to the printer. Both high-side and low-side injection schemes are considered.

A tutorial mode may be selected from the main menu which steps the user through all of the input and output of the intermodulation analysis. Output is sent to the screen rather than to the printer, and changing values and parameters is made extremely simple. This mode is an excellent way to get the "feel" of the program and learn a bit about intermodulation products in the process.

Last Thoughts

Both "Radio System Design Calculations" and "Radio System Interference Analysis" are well-documented, and the latter includes long sections discussing various methods of site management and a thorough review of basic intermodulation product calculations. I think that "Interference" will not make a big splash on the amateur scene, but I do recommend it to repeater owners and coordination bodies as a useful tool in repeater-site preparation and management. "Design Calculations," on the other hand, has several handy features that make the package well worth $35.

The two programs are available on disk (and tape, in some cases) for the Apple II, Commodore 64, IBM PC and PCjr, Kaypro II, and Radio Shack's Color Computer, Model 3/4, and Model 2/16. Contact *Horse Sense Software, PO Box 214, Gardiner MT 58030* for current prices and formats.

TEL MK-800 MEMORY KEYER

A few years back, the state of North Carolina created a large industrial park at the center of the triangle formed by Raleigh, Durham, and Chapel Hill. It became known as the Research Triangle Park. The park was supposed to encourage old businesses to move in and new ones to form. One of the newer businesses is Triangle Electronics Laboratories. A ham-oriented business, they recently came out with the MK-800, which they claim is the most cost-effective digital memory keyer on the market. Having had the opportunity to use one, I heartily agree.

The MK-800 was billed as a "complete memory keyer designed for the experienced contest operator as well as the Novice." While not a Big Gun contester, I have participated in several using a simple, home-brew digital keyer. I felt that I was ready to move up into the world of memory keying and was able to give the MK-800 a shakedown during the 1985 ARRL DX contest.

The unit arrived from TEL packed in a sturdy cardboard box and was cushioned with foam peanuts. Nothing unusual about that, but the end of the power cord was wrapped in its own cushioning layer to keep it from scratching the keyer's case. That was a touch that I'd never seen before and it hinted of a good attention to detail. An eleven-page, spiral soft-bound manual came with the keyer.

Ignoring the manual, just for the moment, I examined the MK-800. It was a compact, two-tone plastic package. The front-panel layout was esthetically quite pleasing. There has been a bad trend lately towards making everything look as if it was either army surplus or crammed with millions of front-panel buttons that only a gnat could push. The MK-800, on the other hand, has a clean, functional, yet friendly look. In the upper center there is an LED display window housing two easy-to-read red LEDs. The upper left corner is home to the sending-speed control. Across the bottom, eight square push-button switches give you control over the most frequently used operating functions. The feel of the switches is very good, very solid, with just the right amount of feedback. Red LEDs over each switch convey information to the user. The switches and knobs are labeled with a pleasant style that is easy to read from a normal operating distance. The unit's colors, black, white, and grey, are arranged in such a way as to give it some personality, yet they allow it to harmoniously blend with almost any station.

So it was a nice paperweight, but was it any good as a keyer? I began to hook it up. Turning it over, I examined the rear panel. Across the top of the machine there are (from left to right) the sidetone switch, a +12-volt jack, a remote-control jack, and the key, paddle, and transmitter relay jacks. Across the bottom we have the power switch and the sidetone tone and volume adjustments.

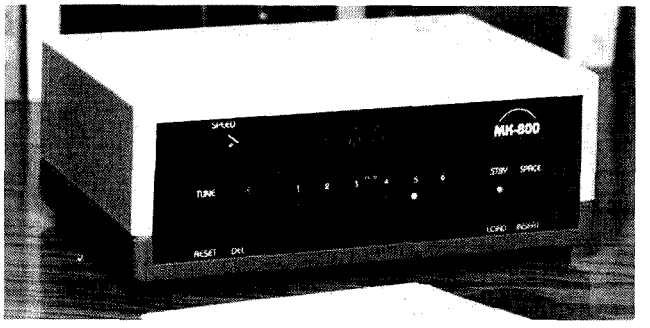
It was time to consult the manual. A quick scan found that page 2 had a description of the required connections. The paddle input wanted a 1/4-inch stereo phone plug with the tip as dits, the center as dahs, and the shield common. Since that was the same setup as my home-brew keyer, I was able to use my existing cable. (The MK-800 does not come with any cables or connnectors, so be ready for a trip to Radio Shack unless you get lucky, as I did.) I also noticed that the paddle inputs are TTL-compatible, so the unit could be controlled by a home computer.

The transmit relay is a fast reed relay. It is wired so that it floats relative to the MK-800's chassis ground. This allows it to be

safely plugged into just about any kind of rig. The keyer end requires another 1/4-inch stereo phone plug. The tip and the center are the relay contacts, while the shield is connected to the MK-800 chassis ground. I made up a cable with connectors and hooked the keyer to my rig.

Checking the connections, I powered up the MK-800 and my rig (a Swan 350). Since I was operating at home, I ran the unit off the standard 110-volt-ac mains. The inclusion of a 110-volt power supply, as well as a +12-volt input, is another example of Triangle Electronics Laboratories bucking a bad trend. All too often we see reasonably priced rigs with exorbitantly priced "optional" power supplies. It seems that many manufacturers expect us to run our equipment off good karma.

When the power switch was on, the MK-800 performed a dramatic power-up test. The indicator LEDs lit up, the two big numeric LED displays started displaying numbers, and finally the unit beeped. It was so much fun to watch that I turned the power off and on again. When the self-test was finished, the numeric display had a "00" on it, indicating that the keyer was ready to go. So I squeezed the paddles and was rewarded with a clean-sounding string of dits and dahs. The MK-800 does not have any transmitting weight adjustments. Instead, it sends according to the recognized standard of one dah being three dit lengths long. The dit length is set by the front-panel speed control. The keyer is iambic, sending alternating dits and dahs when both paddles are squeezed. It also has a 1-dot or -dash memory and is self-completing.



So far it functioned like my home-brew keyer. It was time to try out some of the advanced features. First I took the opportunity to adjust the tone and volume of the sidetone. These adjustments are done on the back of the unit and require a small screwdriver to turn the miniature potentiometers. This would be inconvenient except that these adjustments almost never need changing once they are set.

Flipping through the manual, I found the section labeled "Function Switches." Unfortunately, although there is a good deal of text for each switch, it is unclear and difficult to read. However, it seemed to be saying that all I had to do was press the load switch followed by a memory-select switch and the keyer would load the memory with what I was sending. So I did, and sure enough, it worked. It was much easier than the manual made it out to be, as were all the other functions. It appears that the folks at TEL are great engineers but could use some technical writers.

The MK-800 has six memories. Each memory will hold up to 99 characters. Memories are loaded by pushing the load button, followed by a memory-select button. The large numeric display shows the number of characters entered and is incremented each time a new character is sent to the keyer. When the entire message has been entered, you tell the keyer you are finished by pushing the reset button or any of the memory-select buttons. If you push the reset button the keyer just stops loading and goes back into dumb-keyer mode with your message in memory. If you push a memory-select button the keyer begins sending the contents of the selected memory.

Memory number six is special. It can be configured (via jumpers) to send a three-digit serial number. The leading zeros can be suppressed and all zeros can be sent as the letter O. The serial number can be pre-loaded, automatically incremented, or automatically repeated. Or, if you want, it can be left as a plain memory.

Ninety-nine characters make quite a long message. It doesn't take much familiarity with statistics to calculate the chances of sending a message that long without errors. Fortunately, the MK-800 has provisions for human fallibility. When the inevitable error occured, I was ready, having already read about the delete button. Each time this switch is pressed, the last character in the memory is deleted. Loading resumes at the place that was occupied by the deleted character.

The MK-800 memory keyer from Triangle Electronics Laboratories.

Once the message was loaded, I pushed the memory-select button. The keyer immediately began sending my message, while the display showed a countdown of the number of characters left to send. Pushing the pause button once stopped the transmission when the current character finished. While the unit was paused, I could send code manually with the paddles. Pushing the pause button a second time allowed the message to continue to completion.

When the message was completely sent, the LEDs displayed "00." I pushed the memory-select button a second time, repeating my test message. This time I tried out the break-in function. While the message was going out, I began sending with the paddles. The keyer Immediately stopped its transmission and gave me control of the transmitter relay. While the Swan 350 does not have a break-in feature for CW, it was nice to see that the keyer could handle it.

I was ready to go on the air. First, I loaded up the memories with various convenient messages. Message one was simply "CQ." Message two was "DE" and message three was "KF4PV." This may appear a bit fragmented to the casual observer, but there is method to this madness. The MK-800 lets you string your messages together. For example, by pushing the sequence 1-1-1-2-3-3-3 I could send "CQ CQ CQ DE KF4PV KF4PV KF4PV" and tack on a "K" manually. By manually sending my contact's callsign and pushing the sequence 2-3, I could reply "VR6TC DE KF4PV." (Note—supplied callsign is purely wishful thinking.) The MK-800 allows you to string up to 99 messages together.

After the rest of the memories were loaded with the usual stuff about rigs and weather, it was time to tune up. Putting the Swan into the CW/Tune mode, I pushed the MK-800's tune button. The rigs keyed and meters were dipped. Pushing the tune button a second time unkeyed the rig. Just in case you are forgetful, the tune function turns itself off after ten to fifteen seconds. My unit timed out after thirteen.

I hunted around for a clear frequency, and finally finding one, pushed 1-1-1-2-3-3-3. After a couple of repetitions, a Pennsylvania station answered and we had a pleasant QSO. I was able to keep up a smooth flow, mixing manual and memory keying. My contact, when asked for a critical signal report, said that there was no click and that the signal was easy to read. This indicated that the lack of weighting was no problem and that the relay keying circuit did not change the keying waveform.

The MK-800 makes CW a lot more fun. It's slightly strange to watch your rig sending the obligatory rig and weather discussion in perfect code while you're sitting back with coffee and a magazine. Just don't forget to take over when it finishes.

It was time to get ready for the DX contest. Besides the usual things one needs to plan, I now had to work out my message strategy. Among other things, I decided that one memory needed to contain the word "test." When I tried to enter it, though, I suddenly began having troubles. The machine would load "eist" or "eht" or other nonsense, but not "test."

The MK-800's one-year parts and labor warranty states that the unit should be mailed back to Triangle Electronics Laboratories in case of trouble, but since the contest was coming up soon and Durham is relatively close by, I decided to get in touch with the folks directly first. I described my problems, and the next day was given a new EPROM to substitute for the one in the unit. Once it was installed, the problem with "test" went away completely.

It seems that I had found a problem in the Morse receiving algorithm used in the keyer. "Why should a keyer have a Morse receiver?" was my reaction. To read the straight key, was the answer. The MK-800 performs a running statistical analysis on the straight-key input. It keeps track of the lengths of time that the key is held down and the length of time between key-down periods. Based on the observed times and statistical summing of the past times, it decides whether a dit or dah has been entered. This way it can track a relatively sloppy fist, adjust to changing speeds, and tell when to insert a space if autospace is selected. (As a test, I hooked another keyer to the input of the MK-800 and sent varying speeds of code to the MK-800. The speed was increased from three to fifty words per minute in four seconds. The MK-800 tracked perfectly.) This does cause one limitation, namely that after power-up or reset, the first word received by the unit must contain both dits and dahs.

My problem was caused by a bug in the receiving program. Even though I was using the paddle inputs, these are eventually routed through the receiving program. The problem only occurred when the first word after reset did not contain a character with dits and dahs. It lasted only for the first word. Subsequent words were received correctly. However, the problem was found and fixed in less than a day by the unit's designer, and all units now use the new, correct software. Even allowing for the fact that I did not have to deal with the US Mail, this still ranked as the fastest warranty work I'd ever seen.

Finally, contest day was here. I had put up a new vertical for twenty meters and quick tests showed that it was loading and working well. I hooked up the MK-800, loaded the message buffer (with no problems this time), and fired up the rig. Calling CQ was effortless, and responding to stations calling CQ was also very easy. I had a 3×5 card that showed the order in which to push the memory butttons for CQs or replies. Things were going well as far as keying was concerned, but I wasn't having much success against the megawatters and their thousand-element beams up ten miles. So I cranked up the power from two hundred Watts in to four hundred Watts in. That's when the trouble started.

The keyer's relay suddenly began locking up. Every time I keyed the rig, it stayed until I manually switched back to receive mode. Putting the transceiver back to lower power fixed the problem. Back at high power, the relay locked up again. On a hunch, I disconnected the MK-800 and hooked up my old keyer. Sure enough, the old keyer is aluminum. Somehow, at high power, rf was leaking into the MK-800.

Next, I hooked up a straight key to the Swan. When I touched it, it was hot. Connecting the MK-800 again, I switched back to my longwire antenna. The MK-800 now did not lock up. I went outside and checked out the new vertical and found that there was a poor ground connection. This was causing loose rf in the shack and the plastic keyer case let it through. However, since then I have been unable to make the MK-800 lock up when it was keying a rig connected to a properly grounded antenna.

So the MK-800 keyer functioned very well in a contest, as well as in casual QSOs. I also used it to help train a class of Boy Scouts in Morse code. Here, the really useful feature was the battery backup for the messages. I could load the memories at home with long strings of straight and random text, unplug the unit, and carry it to the Novice class. Nearly six hundred characters at five words per minute will keep a class busy long past the point where they're actually learning anything, so I never ran out of material for the Scouts. In fact, I was able to use the same messages three weeks in a row without having to reload them.

In conclusion, the MK-800 is a very good keyer, with more features than any other keyer that I've seen in its price class ($150). The AEA keyer in the same price class has no memories or power supply. The next higher up AEA unit has ten memories, still no power supply, and costs $50 more than the MK-800. The MK-800 has six memories, automatic serial number, continuous-output speed control, paddle or straight-key input, and input editing functions. The straight-key input speed is com-

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73 Magazine*, Peterborough NH 03458.

pletely independent of the output speed and can vary over a very wide range. It has battery backup for the memories and can operate from +12 V dc or 110 V ac. It is a joy to use and looks good in the shack. The only disadvantages are the somewhat confusing manual and the lack of an earphone jack for the sidetone speaker, but they can be lived with. I recommend the MK-800 to anyone who wants a good, high-performance digital keyer at a good price.

For more information, contact *Triangle Electronics Laboratories, 7016 Windover Drive, Durham NC 27712; (919)-471-6738.*

The IC-27A.

ICOM IC-27A

It all began several months ago when I realized that the summer just wouldn't be complete without a two-meter transceiver in the car. You know how it is: vacation plans that include a lot of driving, scenic tours with visitors from abroad, trips to the beach, short hops into Boston, and the usual daily trips to and from work, the grocery, etc. Obviously, I'd planned to spend a lot of time in the car and wanted a radio that would keep me in touch with my friends via the local repeaters, or even direct/simplex. New England is full of repeaters, and in spite of the rugged terrain you aren't ever out of "sight" of at least one repeater—usually several.

What to buy? The choices are staggering, with at least five or six major manufacturers trying to produce the best and most desirable radio at the lowest possible price. I wanted a full-feature mobile unit with about 25 Watts output, small in size, lightweight, neat in appearance, as well as versatile and convenient. Finally, I decided to opt for the ICOM IC-27A, mainly because of its diminutive tuck-away-anywhere size and its reputation with hams who spend a lot of time on the air from their cars.

The radio comes in two packages: an accessory box and the foam-encased transceiver. The accessory box contains a microphone, a power cord, a short length of coax with connector, and an assortment of plugs and connectors. The power cord is fused. The foam-protected transceiver is packaged with its mobile mounting bracket already in place.

The handsome dark-gray and chrome IC-27A measures a scant 1½"×5½"×7" and weighs a mere 42 ounces. You will like the mounting bracket which allows you to disconnect the transceiver by merely rotating two levers on the sides of the inverted-U-shaped mount.

General Features

The push-to-talk mobile microphone is furnished with a sixteen-button touchtone™ pad for repeater access of autopatch dialing. Just in case your favorite repeater has Private Line™ access, the IC-27A is ready with 32 on-board PL tones, selectable by the main tuning knob and storable in memory. Speaking of memories, there are 9 of them backed up by a seven-year lithium battery. Each memory is capable of storing the receive frequency, the transmit offset, the offset direction, and the PL tone of your choice. There is a scanning feature which you can set to scan either memory channels or vfo channels. There is also a priority-scan function, a convenient arrangement whereby you can select a particular channel and cause the radio to receive that channel whenever a signal appears on it, regardless of where else the radio may be "listening" or scanning. The IC-27A has dual-vfo capability, selectable by front-panel push-button, allowing you to set certain frequencies with vfo A and other frequencies with vfo B. To switch from one to the other merely requires the button to be pushed, a welcome and helpful convenience, especially in an emergency situation.

Transmitter and Receiver Features

The transmitter has two output power levels: 5 Watts and 25 Watts. Under modulation, the deviation is ±5 kHz from center frequency. Spurious emission is more than 60 dB below the carrier level, and the audio quality provided by the 600-Ohm electret condenser microphone is very good indeed. Simplex or duplex operation is selectable, and any offset within the band is programmable in 100-kHz steps.

The frequency coverage of 144 to 148 MHz is provided by a microcomputer-based, 5-kHz/step, digital PLL synthesizer. Frequency stability is within ±1.5 kHz between temperature limits of 14 and 140 degrees Fahrenheit and voltage limits of 11.75 and 15.85 volts dc. Power requirements while transmitting are nominally 13.8 V dc (negative ground) at 6 Amps maximum. Receiving current draw is 0.4 A squelched and 0.6 A with squelch open.

The receiver is a double-conversion superheterodyne using a first intermediate frequency of 10.695 MHz and a second intermediate frequency of 455 kHz. Sensitivity is given two ways: less than 0.2 microvolts for 12-dB Sinad, or less than 0.4 microvolts for 20-dB quieting. The squelch sensitivity is less then 0.15 microvolts. What all of this means to you is that it is a mighty sensitive little critter that can let you hear what you need to hear when you want to hear it. The spurious-response rejection ratio is more than 60 dB, and the receiver selectivity is more than 15 kHz at −6 dB, and more than 30 kHz at −60 dB. This means a filter shape factor of about 2:1, which allows excellent rejection of normally-deviated adjacent-channel signals. You can expect audio output power of up to 2 Watts—enough for normal quiet-car listening.

Scanning

As mentioned earlier, the memory-scan function allows you to monitor nine different preselected channels. The programmed-scan function permits scanning between two programmed frequencies, and full-range scan allows the entire band to be scanned. You can change the scanning speed, and the auto-stop function terminates scanning either when a signal is received or when a channel is free. Priority scan may be operator-selected to stop at a memory channel or a vfo channel, and by using sampling techniques, you can easily check to see if a particular frequency (channel) is occupied or free.

One available option of the IC-27A is a speech synthesizer to verbally announce the receive frequency by simply pushing a button. This permits you to know where you are at any time without the need to take your eyes off the road.

Using Your IC-27A

Here is where you will need to read the manual—several times if you're anything like me. There are so many features and functions that you can't "intuit" the thing and expect to get full performance from it. Like all modern rigs, it requires a learning process to furnish you with its entire capability, so we might just as will start with a short how-to paragraph or two.

The Vfo/Memory switch changes the rig from a memory channel to vfo and back again with a simple push. When you are in the memory-channel mode, a small M appears in the display, and the memory-channel number also appears. Note, however, that even in the vfo mode the memory-channel number still apears. The Vfo switch selects either vfo A or vfo B for tuning. In the out position, vfo A is selected and the vfo A indicator is illuminated in the display. When depressed, the switch selects vfo B, and the vfo indicator goes off. Personally, I would rather have the display show vfo B under these circumstances, but this is a minor point, since if no display is there, you know you're on vfo B.

In vfo operation, the front-knob tuning allows you to step the frequency up in 5-kHz (Tuning Rate switch in) and 15-kHz increments (Tuning Rate switch out). If you tune past the upper band limit of 146 MHz, the frequency automatically reverts to the lower limit of 144 MHz, and vice versa.

If you want to go from, say, 146 MHz to 147 MHz in a quick jump, all you have to do is press the 1 MHz Up button and you're there. To return to the 146-MHz frequency, just keep on depressing the button and the rig will cycle through 147 and 148, back to 144 and 145, and finally to 146 MHz.

The Memory Write/Offset Check button has dual functions. In the simplex mode (when neither DUP− nor DUP+ is displayed) pushing this button writes the displayed vfo frequency into the displayed memory channel. Note that each memory channel stores the operating frequency, the offset frequency, the offset direction, and the subaudible tone frequency, if any. When you are in the duplex mode, pressing this button displays the offset transmit frequency and allows you to listen to the repeater input (while you hold the button down).

The Offset Write button, when held down, causes the offset frequency to be displayed. This can be changed by pressing either the −Duplex, the +Duplex, or the 1 MHz Up button. Each push of the −Duplex button decreases the offset frequency by 100 kHz and each push of the +Duplex button increases it by 100 kHz. Pushing the 1 MHz Up button increases the offset by 1 MHz.

The +Duplex and −Duplex buttons set the offset frequencies in the respective directions by 600 kHz automatically, unless the Offset Write button is also pushed as mentioned before.

The Priority switch turns the priority frequency on or off. Here's a very nice feature: Let's say you are in QSO on a vfo channel, but want to see what's going on, if anything, on a priority channel. Or you're waiting for a friend to call. Just set that channel into memory and push the Priority button. The rig will check that priority channel every five seconds—automatically—for just a moment, enough to allow you to hear your friend when he (or she) calls. Conversely, if you are communicating on a memory channel, this switch will allow you to momentarily look at a vfo (previously set) frequency.

The Rf Power switch sets your transmitter to 25-Watt output in the out position, and to 5-Watt output in the in position.

The Tone Select button, when held in, displays the subaudible tone number on the frequency display panel and causes the Tone indicator to illuminate. While holding this switch on, you can rotate the main tuning knob and select the desired tone frequency.

The frequency display is four large 7-segment display digits representing the digits between 10 MHz and 10 kHz (46.91 representing 146.91 MHz, for example). The small 50, when illuminated, represents the final 5 kHz of the frequency.

The S/Rf indicator indicates S units in receive, and rf-power output in transmit. Note that this is a *relative* indication only and does not measure output power in Watts.

In the receive mode, when the squelch is opened by an incoming signal, a small green LED lights up.

The Tone indicator lights when any tone number other than 00 is set into the rig.

Rear-Panel Controls and Features

You will notice immediately that both the power connector and the antenna connector are at the ends of flexible cables rather than fixed to the rear panel. I asked Evelyn Garrison about this when I saw her at ICOM Day—Rivendell. She told me that the reason for this arrangement is so that the rear of the rig can be mounted nearly flush with a wall or a panel. Neat idea. If you happen to use an external speaker, you can plug it into the panel jack provided.

Underneath the access cover there are several switches and buttons. The CPU Reset switch resets the central processing unit of the microprocessor into its original condition. . .when the power is on. The Scan Speed switch sets the scanning speed to fast or slow, while the Scan-Stop Interval switch sets the interval to either about 9 seconds (long) or 3 seconds (short). The Vfo-Scan Mode switch can be set to PS (programmed scan) or FS (full scan) modes. A really neat feature is the Scan-Stop Function switch which allows the scan to stop on a busy channel or an empty channel.

When your unit is first turned on, the display will read "47.00" (representing 147 MHz) and the memory display will read "0" (representing memory channel 0). In the upper-left corner of the front panel, the M/Vfo switch can be pushed to display the M if you want to select a memory channel. You'll probably want to use the vfo at first, so *don't* push the switch.

Next, rotate the main tuning control to set the desired frequency into the display, using the desired tuning rate of either 5-kHz or 15-kHz steps, selected with the Tuning Rate control switch.

If you'd like to set up another frequency in the other vfo, just push the Vfo switch (marked A/B), also located in the upper-left corner and dial in the new frequency on

that vfo. Now you can have either frequency displayed (or in use) by merely pushing the A/B switch alternately. However, before you transmit, you should check to see which offset frequency is set up in the duplex mode, and whether it is plus or minus the displayed frequency. If neither DUP – nor DUP + is displayed, push the desired button so that your desired offset is displayed. For 146-MHz operation, the offset will usually be DUP – (transmit frequency *below* the receive frequency). Next, push the M W button at the lower-left panel location to see whether the proper (normal) 600 kHz is displayed. If so, you will be in business for most repeaters. If it is not the desired 600 kHz, then you will have to set the desired offset into the unit. To do this, press the Offset Write button in the lower-left portion of the panel, and, while holding it in, push the DUP – button until "0.60" (600 kHz) appears. In the same manner, other offsets can be selected. Finally, check your transmit frequency by pressing the M W button to display it. Let's say you have set up 146.25/146.85 as your channel pair. The display should show DUP – and 46.85. Then, pressing the M W button should show 46.25, which is correct. Now, pressing the mike button (you have plugged in your antenna, I hope) should allow you to access the repeater.

Simplex operation is achieved by merely depressing either DUP – or DUP +, until the display shows no offset. Your transmit frequency will then be the displayed frequency.

On The Air

One of the things you'll want to know is, "How do I sound on the air?" This is where the IC-27A comes into its own. Audio quality reports have always stressed a very clean and easy-to-understand signal, with penty of talk power. . .but no reports of over-deviation. In other words, you'll get through clearly if they can hear you at all. Sometimes, when the going gets "scratchy" and there is a drop out of your signal to the repeater, you may have to "say again, please," but you really didn't expect miracles, did you?

On the receive side, I personally like the recovered audio. For all practical purposes it is quite adequate, even plentiful, *except* in a noisy car with a lot of wind noise, traffic noise, or general conversation going on among your children or friends. However, none of the current rigs I know can solve this problem with their tiny, built-in speakers. There is one solution, of course, and it's the one I prefer—an earphone and microphone headset, one of the featherweight varieties of the type used by pilots or astronauts. ICOM just happens to have one of these little gems, and it exactly fills the bill for mobile use.

So, what can we conclude from all of this? I would like to say that the main premise has been realized: a go-anywhere, reliable, full-featured, and compact 2-meter radio that has built an enviable reputation for itself by virtue of its performance.

A good friend, who has used his IC-27A for the last year or so, swears by this rig as being the best he has ever used. It's a constant companion in his car—as it is in mine.

Suggested retail price for the IC-27A is $369.00. For more information, contact *ICOM America, Inc., 2380-116th Ave. NE, Bellevue WA 98004.*

HAM HELP

We are happy to provide Ham Help listings tree, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye." and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am a disabled ham on a limited income and am looking for parts for a Heathkit SB-300 receiver and an SB-401 transmitter, or a comparable pair for under $200. Can anyone help me get back on the air?

Fred Erickson

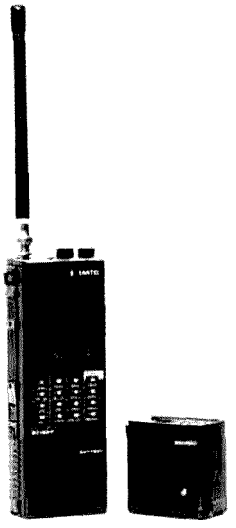
ARCSOFT PUBLISHES SATELLITE HANDBOOK

The *1986 Space Satellite Handbook* from ARCsoft Publishers details 5,612 payloads, platforms, rockets, and pieces of debris in orbit around the Earth, moon, and sun.



Data from NASA, NORAD, and the Smithsonian Observatory are included in this paperback book. Objects are listed with their international number, popular name, launch date, and country of origin. Orbital parameters including period, inclination, apogee, perigee, and NASA radio frequency are shown for each entry.

Complete details about the *Handbook* are available from *ARCsoft Publishers, PO Box 132AM, Woodsboro MD 21798.*

SANTEC ST-20T

Encomm, Inc., has announced a new addition to the Santec line of hand-held radios. The ST-20T covers 142–150.995 MHz with an output power of 5 Watts. Two seven-digit autodial memories allow automatic dialing through a repeater's autopatch. A 16-key keyboard provides access to 32 functions.

For complete information about the ST-20T, contact *Encomm, Inc., 1506 Capital Avenue, Plano TX 75074.*

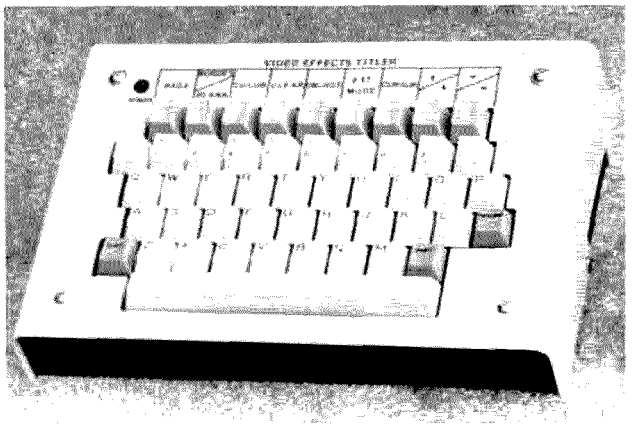
The Santec ST-20T, available from Encomm, Inc.

ONE-TUBE RADIO KIT

A new one-tube radio kit is available from Antique Electronic Supply. The kit comes complete with all of the parts necessary to make a working radio, including a tube and a mounting board. Batteries and headphones are optional. The kit provides the radio experimenter or antique-radio buff the opportunity to learn early electronic construction techniques.

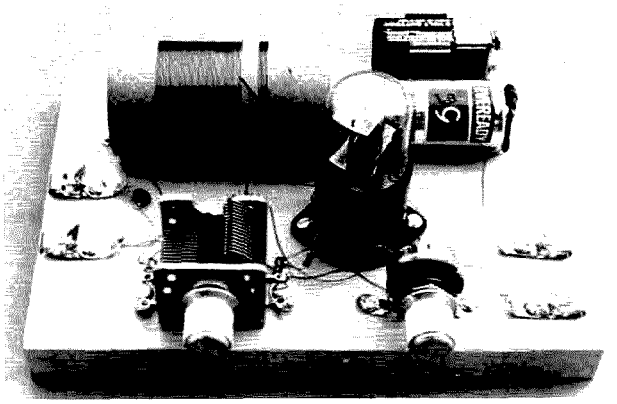
A 20-page catalog of tubes, parts, and books (including information about the kit), is available from *Antique Electronic Supply, 688 West First Street, Tempe AZ 85281; (602)-894-9503.*

TEC-200 IMAGE FILM



TEC-200™ image film, produced in West Germany and sold in the US by the Meadowlake Corporation, is part of a new system for creating printed-circuit etching patterns. TEC-200 film is placed in a standard photocopy machine. A PCB pattern from a magazine or book is transferred to the TEC-200, and then the pattern is transferred to a copper board by using a hot iron. After the film is removed, the board may be etched with any common etching agent. The resist is then removed with a standard solvent.

For detailed information about TEC-200 image film, contact *Meadowlake Corporation, 25 Blanchard Drive, Northport NY 11768; (516)-757-3385.*



MFJ VIDEO TITLER

MFJ Enterprises has announced their Video Effects Titler (VET), a computer-based stand-alone titler for professional and home-video use.

The VET allows the superimposition of 30 pages of color titles over a camera image, or titles may be added over existing video footage during editing. Each page holds eight lines of sixteen upper- and lowercase letters. Each character may be one of 15 colors. Title pages are retained in memory when the VET is turned off or unplugged.

MFJ's Video Effects Titler.

A one-tube receiver from Antique Electronic Supply.

For more details, contact *MFJ Enterprises, Inc., 921 Louisville Road, Starkville MS 39759; (800)-647-1800.*

DAVLE TECH CRIMPING KIT

Davle Tech, Inc., has introduced the CTK-8 crimping kit. The kit includes a crimping tool and an assortment of insulated terminations. The crimping tool will handle insulated or uninsulated terminals, will cut small bolts and wires up to 10 AWG, and will strip the insulation from wires between 10 and 22 AWG.

For complete information, contact *Davle Tech, Inc., 2-05 Banta Place, Fair Lawn NJ 07410; (201)-796-1720.*

EVERETT/CHARLES SUPER MODEM 1200

The Super Modem 1200, available from Everett/Charles Marketing, is a 300/1200-baud modem designed for use with RS-232C-compatible computers and terminals. It is functionally equivalent to the Hayes modem, and uses both Bell 103 and 212A standard tones. Other features include autodial, redial, touchtone™ or pulse dialing, and full- or half-duplex operation.

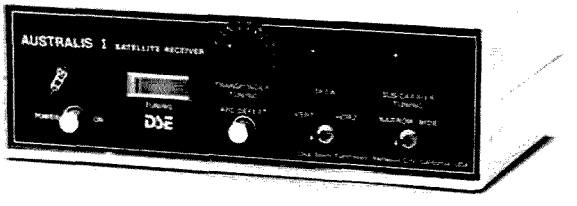
For complete details, contact *Everett/Charles Marketing Services, Inc., 6101 Cherry Avenue, Fontana CA 92335; (800)-443-1860.*

DSE SATELLITE RECEIVER KIT

The Australis I satellite receiver kit is now available from Dick Smith Electronics. The kit has been designed to make construction and alignment as simple as possible—only a standard multimeter and a signal source are required. The front and rear panels are silk-screened, and the circuit board is solder-masked fiberglass with a screened component overlay.

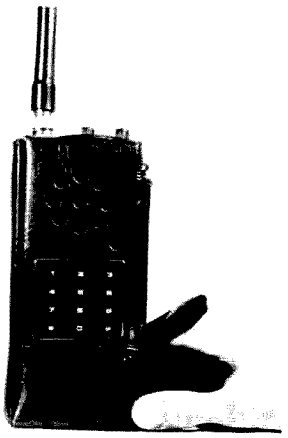
For more information about the Australis I, contact *Dick Smith Electronics, PO Box 8021, Redwood City CA 94063.*

CES BEAMCALC SOFTWARE TOOLBOX



Communications Electronics Specialists, Inc., has announced the CES BeamCalc Software Toolbox for the Commodore 64 and Apple II computers. The software calculates beam headings from the operator's location to any location in the world. Also displayed are the latitude and longitude of the selected location, the distance in statute and nautical miles, the time difference from UTC, the DX zone number, postal rates, the number of IRCs required for a postal reply, and QSL bureau information.

Other programs in the Toolbox handle line-of-sight calculations, satellite tracking, moon tracking, and solar-phenomena predictions.



For more information, call or write *CES, Inc., 803C South Orlando Avenue, Winter Park FL 32789; (800)-327-9956.*

CTCSS ENCODER ADDS DIP-SWITCH PROGRAMMING

Selectone Corporation has redesigned their model ST-130 Digitone CTCSS encoder to include a six-position DIP switch for tone programming. The new model provides 37 CTCSS frequencies between 67 Hz and 250.3 Hz. The unit operates on 5.5 V dc and draws less than 2 mA. The output level is adjustable to a maximum of 1 V rms. The ST-130 is compatible with all standard CTCSS systems, including Private Line™ and Channel Guard™.

The Australis I satellite receiver from DSE.

Crowley Manufacturing's Delta-Zulu HT case.

For more information, please contact *Selectone Corporation, 28301 Industrial Blvd., Suite L, Hayward CA 94545.*

DELTA-ZULU IC-2AT CASE

Crowley Manufacturing has introduced the Delta-Zulu soft-vinyl case designed to fit the IC-2AT/3AT/4AT series of hand-held radios. A clear plastic window gives access to the keypad, and a zippered battery door allows the user to change the battery pack without removing the case. There are openings on the top and back of the case for controls and plugs. The Delta-Zulu case is available in either black or burgundy and can be used with or without a belt clip.

For more information, contact *Crowley Manufacturing Company, 95 Federal Street, Lynn MA 01905.*

MICROWAVE MODULES 2M GaAsFET MULTIMODE

Microwave Modules of Liverpool, England, has announced the MMT144/28R solid-state multimode transverter. The MMT144/28R can be used with any 28-30-MHz transceiver having a low-level (.25-300-mW) power output.

The receive section includes a noise-matched NEC GaAsFET preamplifier and a high-level double-balanced mixer, providing excellent strong-signal-handling characteristics and immunity to cross modulation.

The transmit converter provides an output of 25 Watts and incorporates an alc circuit to ensure a clean signal. A visual indication of relative power output is given by an LED bar-graph display.

Microwave Modules' MMT144/28R 2m transverter.

Dc power requirements are 13.8 V dc at 6 Amps. The alc range is 20 dB. The receiver's noise figure is 2 dB or better with a third-order intercept point of 19 dBm.

For more information, please contact *The PX Shack, 52 Stonewyck Drive, Belle Mead NJ 08502; (201)-874-6013.*

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Happy New Year, one and all! I do hope that this year will bring each and every one of you everything that your hearts desire! For many of you, that wish has been a program to put your personal computer onto RTTY, and I hope that this column has helped more than a few of you fulfill that wish.

Now with that said and with a bit of a lump in my throat, let me quickly apologize to those of you whom I am about to upset. By means of an allusion last month, I hinted that a particularly delicious computer would be the subject of this month's software review. Unfortunately, I am still waiting for at least one response to an inquiry I sent out. So, rather than just spin my wheels, let me tell those of you who have managed to appropriate or acquire a big blue box (IBM PC or compatible) what's in the RTTY cards for you.

A couple of years ago, when an owner of an IBM-style computer wrote me for RTTY information, all I had to say was "tough luck," but now, with the proliferation of these machines in the hands of hams, all this has changed.

A rather typical looking station is an IBM PC with 128K of RAM, serial communications card, RS-232-to-TTL drivers based on a 1489-1488 chip pair, and all this feeding a Flesher TU-170 interfaced to the ham rig.

Software in use at this station is a program advertised by Bob Johnson AA4L, 11305 Rums Hill, Raleigh NC 27614, which is apparently available for a formatted disk and a few dollars. It is rumored to be available as well on several bulletin boards, usually called "TTY22."

The program provides 60-, 75-, and 100-wpm Murray (Baudot) transmission, several disk messages, and can key the transmitter via RS-232 signals and the 1489-1488 pair. The display is not split-screen; receive and transmit data are interspaced. However, there is a buffer to type ahead for transmit while receiving.

One of the hams using this program tells me that he has added a storage slot for the callsign of the current station being worked, function keys to switch speeds, disk recording of callsigns after a QSO with duplicate checking, disk message interrupt, and "several other things." In addition, he eliminated some of the "cumbersome" features, like a start-up logo, speed-select menu, and such. Just shows you what can be done with some of the user-supplied software traded and modified on "the boards."

Another of you tells me that his IBM PC interfaces to his rig through a CP-1 and uses the Hamcom program, version 3A, from Emile F. Alline, Jr. NE5S, of Metairie LA. I am told that this program encompasses Murray, ASCII, and CW, as well as code practice. Saving data to disk, printing out to the printer, and storage of "canned" messages are also supported. Sounds like another interesting program, although I have no idea as to the cost.

Another program in use is by Glenn Welman KF4NB, 3301 Pastern Ct., Lexington KY 40513, and is distributed as "freeware." In the literature, which I have seen an abstract of, the author says to share the program with others who are interested in RTTY, but not to sell or barter the program. When the program is passed along, only the unmodified version, along with the guidelines, should be included. A self-addressed stamped envelope to the author will get you the latest update, and any and all contributions will be accepted.

The program requires an IBM PC or compatible, with at least one drive and 128K of RAM, an asynchronous communications adapter, and DOS version 1.1 or better. It would appear that the program will function on a PCjr with some limitations.

Display is in either monochrome or color, with 80 x 25 and 40 x 25 character modes available. The split-screen has receive data on top, and transmit on bottom, and run-time information (including current date and time and elapsed time since the last ID) is in the center of the screen. Meanwhile, the bottom of the screen contains error codes, information messages, and function-key information.

It even maintains the old CR-CR-LF-LTRS end-of-line sequence required by manual teleprinters!

Baud rates equivalent to Murray 60, 67, 75, and 100 words per minute are supported, as well as ASCII baud rates of 100, 110, 300, 1200, and more! There's even a 4K buffer for you to fill from the keyboard while receiving.

All this in a program that apparently is available for the asking, for which the author only asks you to send him what you think it's worth. Sounds good!

Now, as to the hardware itself, a few of you have found it less than perfect for amateur use. One of you tells me that rf in the shack gets the PC excited. That was cured by grounding the keyboard, monitor, and CPU cabinet to a six-foot ground rod driven into the basement floor. Another of you must be having similar problems, in that there is so much rf in the shack, that RTTY output must be limited to ten Watts or so, or else. . .

My thanks this month to Bo Barry W4GHV of Las Cruces NM, Elliot Hamilton WA9JIQ of Arlington Heights IL, Anson R. Hyde, M.D. K4EK of Virginia Beach VA, and our old friend from the 68xx camp, Clay Abrams K6AEP, of San Jose CA, for their many contributions regarding their experiences with the PC.

Other machines have not been so lucky, however, and I still am at a loss for our friends running the Osborne 1. Is anyone out there running an Osborne 1 on RTTY? This column has several devoted—but frustrated—readers who would love to put their attaches on RTTY but lack the software. Any knowledgeable folks out there? Let me know. Thanks.

Ditto on the Timex/Sinclair. It seems that a lot of folks picked one of these little computers up for a song or got one as a premium with this or that electronic (or nonelectronic) purchase and now look wistfully at the keyboard and display and wonder. Well, so do I. I have received questions, but few answers. If anyone is running one of these wonders on RTTY, drop me a line, OK?

Okay, folks, listen up—now I've got a problem. A few months ago, I mentioned that Bill Davidson KW4J is using a partic-

The RTTY corner of C. A. Waterhouse W4INM's shack.

ular RTTY program on his TI-99/4A. I need to contact you, Bill, and can't find your address anywhere. So, if Bill is reading this month's column, or someone is reading it who knows Bill and can get this to his attention, I would appreciate a little note in the mail or via CompuServe. Thanks.

Received a note from Robert Holland, M.D., Ph.D. K7PCJ who is having some trouble finding the XR-2206 function generator used in the simple AFSK generator detailed here a few months back. Well, when I wrote that column the chip was hanging prominently on the wall at my local Radio Shack. Unfortunately, it has been dropped from their latest catalog. It is still quite available, however, from a variety of sources. James Electronics includes it in their blister-packed wall display available from a number of local outlets, as does Digi-Key and a number of other parts suppliers. Look around at some of your local electronics stores and you may be surprised.

Ron Vickery, one of our readers from Ellenboro NC, writes a few, as he puts it, "basic questions." He has acquired an old Allied R-100 general-coverage receiver and wonders if he can use it on RTTY. Ah, Allied Radio—that sure brings back memories. Back in my Novice days we used to pick our parts from thick newsprint catalogs produced by Allied, Lafayette, and several others. Now, but a memory. Oh well, back to the question. Ron says that the receiver has a beat-frequency oscillator (bfo) and implies that it receives sideband as well. But, he keeps seeing where the ads push digital dials and such for mucho buckolas.

Ron, if the receiver receives sideband it should work fine on RTTY. Receiving the two modes requires much the same technique, and drift that would render a RTTY signal unreceivable would render a sideband signal unintelligible. What you will need is any of the "interface" boxes that we used to call terminal units, or TUs, also known as demodulators. This box takes the audio, tapped from the earphone jack or speaker, and converts it into the on-off or plus-minus voltages of a TTY loop or RS-232 computer interface.

You said that you have a CoCo (TRS-80 Color Computer), and that will be a fine computer to get onto RTTY with. We will be covering some of the available software in the very near future right here, so stay tuned.

On the air with AMTOR, Larry Hawes KA4QZQ of Venice FL is looking for the best filtering between the receiver and his AMTOR unit. Well, Larry, I guess the key word is "active." Those little op amps and chips have pretty much replaced the boards of donuts that we used to have in the days of 88-mH toroidal coils. I have seen a number of active-filtering schemes, and I don't have any current information as to which is the "best," and why. Will try to print what I can, though, as your cohorts let me know what they are using. (Hint, hint.)

Getting kids into amateur radio has always seemed like a good thing to do, and David Peterson in Osseo, Wisconsin, is doing just that by incorporating amateur radio into his high-school communications class at Osseo-Fairchild High School. I do wish you the best of luck, and hope that the material I sent you at your request will be a help.

While it isn't exactly RTTY, I have never been bound by that before, so let me tackle a question sent in by Guy Roussel, M.D., of Lincoln, Maine. Guy is interested in the WEFAX program, a program designed to decode weather and other facsimile transmissions and display them on the screen of a CoCo. Specifically, he would like to find a version of the program for the Commodore 64 computer. Well, sorry, Guy, but when I put that question to Marty Goodman, M.D., one of the sources of the program, he told me that the program just cannot be adapted to the C-64. Problems include the less powerful CPU in the C-64, as well as other restrictions in hardware. With hardware prices falling, why not bite the bullet and switch over? I think you will be surprised at the power of the 6809 CPU, which can even run a sophisticated system like the UNIX-like OS-9 and still be friendly enough to play games.

Well, I asked about a "shack of the month" photo, and here is the first one. This is the RTTY corner of C. A. Waterhouse W4INM. He has a number of Teletype® Model 32 and 33 machines and agrees with me that there is no such thing as a "standard" call control unit. It looks like quite a setup; one only wonders what the XYL says when all the machines are chattering away! Thanks for the photo, and I took forward to receiving others.

As always, I enjoy all your comments and questions, which have been coming in both via mail and CompuServe. I'm trying to keep up with the responses, and I think the stack on my desk is smaller than ever. Of course, electronic mail is normally answered on the same day, so send it to 75036,2501 on CompuServe, and I'll see what I can do. Yes, the reprint list is still available for a self-addressed, stamped envelope. It grows every now and then, so if you think you might be missing something, I won't be upset if you ask for another. Just drop me a line, with an SASE to the above address.

More next month on a variety of topics. With the spectrum ranging from grease-bangers to computers to WEFAX, I guess you never know what might turn up in "RTTY Loop."

ABOVE AND BEYOND

Peter H. Putman KT2B
84 Burnham Road
Morris Plains NJ 07950

Before I go on with this month's column, let me say that while I do consider myself a bit more proficient on VHF/UHF than the average ham, being an "expert" of sorts doesn't protect one from our dear friend Mr. Murphy when he decides to play havoc with a station. Let's now consider a case in point: The use (and misuse) of mast-mounted preamplifiers.

Why use a mast-mounted preamp at all? (Why, indeed, I've been asking myself, as you'll soon see!) There are a few reasons, but the primary reason is to provide sufficient preamplification of weak signals to overcome transmission-line losses.

Let's assume you are trying to work weak signals on 432 MHz. Assume for the moment that your receiver front end has a noise figure of 3 dB. Assume also that you are using a run of 8214 Belden coax and have feedline losses of 3 dB. If you want to hear a signal in the noise or at the threshold of your receiver noise, you've got to make up at least 9 dB of gain someplace! This would overcome the 3 dB loss of your feedline and also the additional noise generated by such a preamp, leaving you with about 3-5 dB of additional signal to work with, placing that same signal at about S½ copy. Still not a great signal, however.

The problem is that you can't use the preamp at the receiver input, for you've already added 3 dB of loss in your feedline to the already weak signal, putting it 6 dB below the threshold at which you can detect it (3 dB below the noise figure, which is also 3 dB)!

The answer is to put the preamp at the antenna, or tower head. Only here can the full benefits of a preamp be realized in such a situation, for the signal is already 3 dB stronger when it arrives just by overcoming feedline loss. Assume you feel that a signal must be at least S1 for you to be able to copy it clearly. Then your preamp must be able to supply at least 12 dB of gain: 3 dB to overcome your receiver's noise figure, 3 dB to overcome the feedline loss, and 6 dB to raise the signal from noise threshold to about S1 copy.

This presupposes that your preamp generates no noise—which is not the case. It, too, will generate a certain amount of noise, and this noise will have to be added to the overall calculations. Now let's get a bit more up-to-date and revise those figures to take into account the latest developments in receiver front-end design, transmission lines, and preamplifiers.

Now your 432-MHz receiver has a noise figure of 2 dB, using the latest in microwave bipolar transistors. And you've spent a few bucks on a GaAsFET preamp with a claimed noise figure of 1 dB. You've already made up 3 dB of difference right there over the previous setup. And you also decide to change to Belden 9913 coaxial cable, which gives you only 1.5 dB of loss.

Now you have to overcome a total of 4.5 dB instead of 6-8 dB using the previous setup (and that assumes the previous setup used a preamp with noise figure of 2 dB). If your preamp has a claimed gain figure of 15 dB, that means that the net gain at the receiver front-end stage (after overcoming front-end noise) is 10.5 dB, which is almost a two-S-unit increase! Now the signal that was in the noise is clearly readable. Quite a difference from before!

Of course, you can make additional improvements by going to lower-loss transmission lines and bigger antenna arrays. The problem is that there will always be *another* signal "just in the noise" to confound and frustrate you. Ah, the problems of the UHF afficionado . . .

To get back to the story, I decided that a mast-mounted preamp was just the ticket. Murphy was standing behind me at the ticket window, looking over my shoulder. Was I in for it!

By way of setting the scene, I use a Kenwood TS-430S at 28 MHz as my i-f for a 432-MHz microwave module. The noise figure of said module is about 1.7 dB. I also use an array of four F9FT 21-element yagis on an H-frame to yield about 20 dB or so over an isotropic dipole.

The transverter and antennas are connected by about 70 feet of Prodelin 1/2" Spiroline cable, which has about 1.5 dB of loss per 100' run. My loss then calculates to about 1 dB, meaning that I would have to overcome about 2.7 dB of noise and loss to compensate. If I wanted to bring a signal that was "in the noise" up to about S1, I would need a total of 9 dB of gain.

Another 6 dB would raise it to S2, so the total gain of the preamp would have to be about 16 dB (assuming -1 dB for the noise generated by the preamplifier). The Advanced Receiver Research 432 VDG seemed like just the thing, as it claimed 16 dB of gain with a .5 dB noise figure.

Initially, I tried two Dow-Key relays to put the preamp in the line on receive and take it out on transmit. The relays were SPDT types, and a footswitch in the shack operated them along with the transverter standby switch and amplifier bias control. When 26 volts was sent up the tower, the relays energized and the preamp was bypassed. This worked fine for about one day before Murphy got to it. Apparently, a spike got into the GaAsFET and blew it to pieces, for I hadn't sufficiently protected against spikes by using bypass capacitors and diodes across the relay coils. SCORE: Murphy 1, KT2B 0.

No problem. I connected a 1N4004 rectifier and bypass capacitor across each relay contact and, after repairing the blown device, re-installed the preamp on the tower. So far, so good. This particular lashup lasted almost a week before Murphy discovered the rf-sensed keying line in my MMT 432/28S transverter. While demonstrating the station to a friend, the microphone gain was inadvertently set too high, and the TS-430 keyed, driving the transverter sufficiently so that the Mirage D1010N amplifier I was using fired a bolt of about 50 Watts up the feedline to the input of the preamp. Kaboom! SCORE: Murphy 2, KT2B 0.

Long hours of research and thought

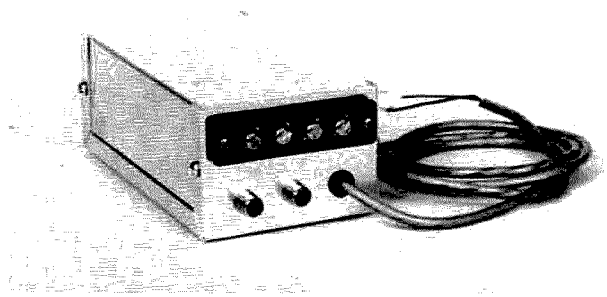


Photo A. The ARR sequencer. The two RCA jacks bring in the PTT line and key the bias for the amplifier. Additional closures are available through the terminal strip.

brought this revelation: Why not energize the relays on receive and have them drop-out on transmit! This would provide additional protection against lightning strikes and mysterious voltage transients floating about when the station was off the air. Additionally, should the preamp fail while in use, I had but to cut off the operating voltage and it would be permanently bypassed by the coax relays. A stroke of genius!

In addition, I would employ a system of cascading relays to ensure that everything was keyed in the proper sequence—preamp out, relays switched, amplifier bias set, and finally, transverter in standby. (Needless to say, I disconnected the rf-sensing feature to avoid problems in that area!)

A chassis was fabricated for the sequencer. Four relays were scrounged from the junk box, and a power supply and switching circuit were devised. Each relay was a DPST type, which allowed me to use the second set of contacts to key the next relay in line. In theory, it should provide enough delay for everything to key up in order and prevent another rf blast into the preamp. When the transmit line was released, the relays would release in sequence, or so I hoped.

It just didn't work out that way, however, when Murphy got through with it. After several weeks of serious 432 DXing, he payed another visit to the shack and somehow got the sequence all jumbled up. Sure, they all keyed in the right order, but dropped out in the wrong order, and eventually one relay got caught in the wrong position. SCORE: Murphy 3, KT2B 0.

Shortly after this, I happened to be at the Dayton Hamvention and came across Jay Rusgrove W1VD at Advanced Receiver Research. I suspect it was because of me that he had just introduced a new product: a mast-mounted amplifier sequencer, using linear circuits to achieve a consistent ramping effect so that all devices connected to it would key-up and drop-out at the same time, every time.

At $49.95 it seemed reasonable. (I had already spent almost that in GaAsFET repairs!) I purchased his last unit. The unit was installed in a box with all connections brought out to one end for easy access (see photo A). The unit employs four relays as it comes from ARR: one SPST normally-closed relay, and three SPST normally-open relays.

The first relay supplies the voltage to the preamp and antenna relay, while the next three key-up and set bias, set PTT lines, or put transverters into standby. The unit employs a 555 timer to ensure a solid closure no matter how short the PTT interval is. This in turn drives an LM3900 which functions as an integrator to provide a linear up and down ramp effect to drive the two dual comparators, types LM319.

Each has a threshold-voltage level on its input and each changes state on the up and down ramps according to that trigger voltage, keying the appropriate relay. The entire sequence takes about 30 milliseconds, which is enough to ensure that everything is settled before rf is applied.

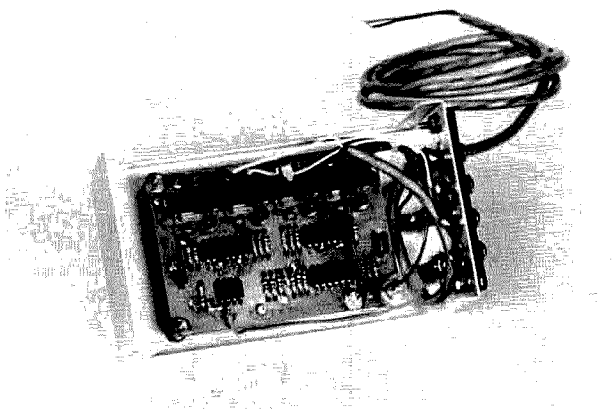

Photo B. The sequencer with cover removed. Two SPST NO-type relays are installed, upper left on the circuit board.

Although Jay recommends that the preamp and antenna relay be keyed at the same time through the first relay, which is the SPST NC type, I couldn't do this (because of problems with different supply voltages) until I used a voltage-dropping scheme at the tower head. The 432 VDG preamp uses a 5-volt regulator and 28 volts would have been too much to handle, so I dropped the voltage with a zener and resistor to about 15 volts. Unfortunately, I forgot to consult with Murphy after consulting with Jay, and he apparently got miffed. After about three weeks of moderately reliable operation, the zener either failed or the resistor opened. SCORE: Murphy 4, KT2B 0.

I called Jay again and advised him of the problem. After a short discussion (no, he didn't offer me stock in the company) I ordered a second SPST NC relay. My idea was first to remove the voltage from the preamp (13.8 V dc) and then release the voltage from the relays (26 V dc). The unit was modified accordingly, and Photo B shows a close-up of the sequencer with the new relay installed.

The Magnecraft type W171DIP relays on the upper-left portion of the board are both SPST NC types, and the W107DIP relays to the right are both SPST NO. The order of firing is left to right on transmit and right to left on receive. The power cord goes to a companion power supply which provides 13.8 and 26 volts for both the transverters and the mast-mounted preamp combination.

Believe it or not, this setup made it all the way through the September VHF Contest. I was able to work my weak signals—including WB4SLM from Grid EM85 in western North Carolina, over 500 miles away. Finally, I could reap the benefits of a mast-mounted GaAsFET without fear of accidentally blowing up the preamp.

Murphy was stumped! Had I actually thwarted him at last? Not exactly, as it turned out. Murphy had one more card to play.

You guessed it. I blew up the sequencer. Apparently, while I was testing a few 4CX250 power tubes at 432 MHz for output, one bad tube either shorted out or went into oscillation. Something got into the grid bias line, and the relay which keyed the operating bias of −135 volts shorted internally, arcing through the LM319 comparator and taking the LM3900 integrator with it. As an added bonus and at no additional charge for his services, Murphy made sure that the preamplifier got a blast from the tube. SCORE: Murphy 5½, KT2B 0. (The 1/2 point was for the sequencer!)

Which brings us to the present. A recent trade brought in about 50' of ⅞" Andrew heliax cable, and another trade brought the two N connectors required. It can handle lots of power, doesn't generate any noise, and will give me another 1 dB of gain just by its lower loss rating. Best of all, I don't have to sequence it. Murphy is fuming now and has packed his bags to head out to parts unknown.

Let me add that I haven't given up on the idea of a mast-mounted preamplifier, however. A second ARR sequencer is in the line keying the transverter and amplifier bias, so I can confirm that the previous problem is not likely to happen again before I install my sixth preamp on the tower. Besides, think of the weak signals I could work with a 16-dB preamp and ⅞" hardline from a 20-dB array at 50 feet...

From the mailbag this month comes a letter by way of the Philippines. Jose Antonio B. Conde of Cebu City writes to tell of the increased activity on 144-MHz FM. Most operators, he says, use the ICOM 27A and small yagis. Other operators employ Kenwood TR-7950 rigs, and with all the conversation and QRM it makes for a lively situation on 144 MHz.

He also suspects that there are a few bootleggers around (no surprise here, we've got plenty on 2-meter FM, Tony!) but most QRM is not really intentional; it's just the product of too many stations on a small band.

Tony also inquires as to what could be purchased in the $500–$600 range in US dollars to outfit a good VHF-multimode station.

Well, in this country, Tony, you could put together an ICOM 271 multimode and KLM or Cushcraft beam for about $600 and change. Or you could use an ICOM 290H and Mirage amplifier together with that same beam for about $675.00. Of course, there are lots of used pieces of equipment around. By far the cheapest way to get on 2m SSB is to use a 144-MHz transverter with a low-band radio; such a transverter, amplifier, and antenna in US dollars would run about $425, giving you 100 Watts to a good-sized yagi. Hope this answers your question.

Frank White W8OY from Mentor, Ohio, writes in to inquire where he can locate RG-17 or RG-18 coaxial cable. For those readers who are unfamiliar with this type, it's a 50-Ohm, ¾"-diameter, armor-jacketed transmission line that was quite popular with the armed services. It resembles garden hose, and the braid on the outside is quite strong and difficult to break through.

Frank, I don't know of any direct sources but here are some addresses you might try to locate this cable, or an acceptable substitute:

Madison Electronics Supply 3621 Fannin Street Houston TX 77004 (1-800-231-3057)	Nemal Electronics 12240 NE 14th Ave. Miami FL 33161 (1-305-893-3924)
Certified Communications 4138 South Ferris Fremont MI 49412 (1-616-924-4561)	Texas Towers 1108 Summit Ave. Suite 4 Plano TX 75074 (1-800-272-3467)

Frankly, for the cost of such cable you might be better advised to use either ½" hardline or Belden 9913 RG-8/U coax. Either is more plentiful and both can handle up to a kW on 144 MHz with minimal loss.

Addendum

The reading public can be quite unmerciful at times, but in this case it is justified. Yours truly made a few bonehead statements in the October, 1985, "Above and Beyond" column regarding stacking of beams for extra gain in VHF and UHF operation.

Perhaps the biggest mistake was to try and condense a complex topic into a few paragraphs. I'll try to address a few mistakes as quickly as I can: First of all, increasing the size of an array at VHF or UHF (or at *any* frequency, for that matter) *increases* rather than *decreases* the aperture of the array (much like using a lower F-stop number on a camera lense; as you "open up" the aperture, more light is transmitted). Secondly, the front-to-back ratio can remain the same or improve, depending on the construction of the array. Thirdly, in many cases optimal gain achieved in stacked arrays actually can increase the side-lobe pattern, not decrease it. Side lobes *can* be decreased by changing the spacing between different elements of the array, but at the cost of gain. Also, the pattern of the antenna will change with the above adjustments. About the only thing I will say with certainty is that stacking beams does offer increased forward gain, and the gain figure as well as the radiation angle will vary depending on the distance between each element of the array (such as between four identical 432-MHz yagis).

As was stated in the October column, the recommended minimum spacing between yagis in such an array is at least half the boom length. For some of the newer long-boom high-gain yagis, this figure changes considerably. Again, the spacing between yagis will determine not only gain but radiation angle as well, often increasing apparent gain over long paths to more than 3 dB. Your best bet is to read more about it; there are several articles by Joe Reisert W1JR that deal with the subject more scientifically in the April and May, 1985, issues of *Ham Radio*. I'll try to present a more detailed and technically accurate treatment of this subject in a future column.

HAM HELP

I'm looking for a schematic and service information for a CR1/43044 transmitter/receiver manufactured by the Colonial Radio Corporation.

Mickey Knight N4LVN
144 Del Ray Court
King NC 27021

I am looking for an owner's manual or service information for a Hammarlund HQ-170 receiver. Please let me know how much it will cost.

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73 Magazine, Pine Street, Peterborough NH 03458, USA, Attn: International Editor.

CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol, Cyprus

Radio activity in Cyprus during the last few months was rather restricted, mainly due to propagation. But the regular dozen or so 5B4s were active mainly on 20m. Also during this summer, many foreign hams who came on holiday were working /5B4. These were mostly British, German, and other European amateurs. They usually operated on 2m with small HTs, but some operated also on HF from the shacks of 5B4 stations.

A very pleasant visit to my QTH was that by Frank DJ@QZ, who operated from my shack on HF. Also, I had another visit from a very good friend with whom I had lots of QSOs, OM Ezzat SU1ER, who also was visiting Cyprus as a tourist. Ezzat also met other 5B4s in Nicosia, who entertained him at their local radio club. We do hope that visiting amateurs in Cyprus will contact 5B4s when they arrive. We are sure that they will find the friendship and brotherhood that comes out of our hobby.

An activity organized by CARS for the first time ever was a national VHF contest. This took place in the 2nd week of August, and the winner will receive the CARS president's cup. We do hope to have more contests in the future.

Some interest is shown currently in RTTY and satellite operation. On RTTY, regular operators 5B4OP in Nicosia, and 5B4JE in Limassol with his harmonic, George 5B4OV. There also are a few other RTTY operators, but they are not very active. On satellite work we have Akis 5B4OA working OSCAR 10. Other OSCAR users are 5B4HF and 5B4KP (when he is in Cyprus). Trying to get ready for OSCAR are 5B4NG, 5B4RU, and 5B4CV. 5B4JE hopes to operate OSCAR 10 from the shack of 5B4CV, and during the winter will have a go at RS satellites. I would like to thank, through this column, Giannis SV1DO, who sent me a program for OSCAR and gave me all the recent Keplerian elements. It gave me a few moments of excitement and pleasure when I heard OSCAR for the first time.

Official permission was given to Cyprus amateurs for the use of special prefix 5B25 by any station wishing to do so—from the 16th of August until the end of last year—to commemorate the 25th anniversary of the independence of the Republic of Cyprus. It seemed to be a popular prefix because when 5B4s appeared on the bands using it, terrific pileups were created.

ZC4 activity at the moment comes mostly from the base of Dhekelia. Stations at the Episkopi base are not active at the moment. ZC4AP was heard coming from the Akrotiri base, and my very good friend Andy ZC4AM told me that as of October he will be active as ZC4AM/P from the salt lake of Akrotiri within the base area.

ZC4MR, 5B25JE (5B4JE), and 5B25MF (5B4MF) are checking regularly with the W7PHO Family Hour net with the very good company of Len KB2HK, net controller. Let's hope that propagation during the winter will improve, and we will be very happy to meet new stations on this net.

CZECHOSLOVAKIA

Rudolf Karaba (OK3KFO ARC)
Komenského 1477/8
955 01 Topolcany
Czechoslovakia

The evaluation of the best Czech and Moravian radio amateurs takes place annually. One Friday in January, 1985, the best radio amateurs met in Tisnov to receive prizes for their many years of service. The placings were determined by a vote of the members of the Czechoslovak Central Council of radio amateurs. First place was won by a world champion in radio-orientation racing and a master of sports, Ing. Mojmir Sukenik, with 270 points. Pavel Sir OK1AIY received 183 points and second place for his work on UHF. Third place went to Ing. Karmasin OK2FD for his work on HF (166 points).

In the 1984 VK/ZL RTTY DX Contest, three Czech radio clubs acheived the top scores in the multi-multi category. They occupied the first 3 places in the world in this order: OK3KJF, OK3RJB, and OK3KXJ.

Besides that, OK2-21478 won first place in the world in the SWL category. OK1DRX improved his RTTY operation by means of a ZX-Spectrum computer, and by means of this computer made contact with OK1VAT in the 145-MHz band.

AMSAT-OSCAR 10

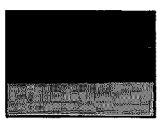
From the end of April till the beginning of October, 1984, Jenda OK2EH, operating CW, made 150 contacts with 56 DXCC countries. He has been using electronic equipment of a multiplier type with an REE3OB electron tube. The receiver is an MWEc with a converter. The antennas are a 12-element yagi for receiving and a 15-element yagi or a spiral antenna with 10 turns for transmission. All of them are adjustable in azimuth and elevation.

Radio club OK1KRA wrote that it had worked the following Czechoslovak stations: OK1AIY, OK1KHI/P, OK1DIG, OK1KTL/P, OK1DKS, OK1DTL, OK2AQK, OK3AU, and OK3RMW. OK1KRA is the first station from Czechoslovakia and the first from the socialist states that has worked 57 DXCC countries.

Some remarks made by an operator at OK1VPZ:

- It is necessary to listen closely. Our antennas are a 16-element F9FT yagi and a 2 x 9-element F9FT yagi crossed for a circular polarization with a preamplifier.
- For these antennas, is necessary to have an exact prediction of the position of the satellite. It would be best to use a computer.

In one and a half years, Ondrej OK3AU has made, in mode B, about 2500 contacts with 67 countries. He has worked under other callsigns as well: OK5MIR, OK5KWA, and OK@WCY. Ondrej confirmed the sad reality that unnecessary overloading of the converter in mode B has not been changing for the better at all—on the contrary, the number of stations using enormous erp without improving their receiver system has increased.



Vlasta OK2VPA from Opava has also been working through AO-10/B, where she has made 100 contacts. She is most proud of her contact with the VS6XLA in Hong Kong.

RS SATELLITES

At present, during the period of quiet sunspots, there are good conditions for working via the RS satellites. At the beginning of 1985, OK3AU, OK3FH, and OK3ZFA were working regularly on them. Also, stations from Bohemia and Moravia, OK1DJW, OK1BMW, and OK2AQK, appeared. From time to time, some unique stations with special prefixes (EU, EO, EW, EV), station UA@KAJ from Kamchatka, and the JW stations from Spicbergy can be heard.

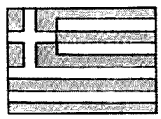
Michal OK2BXF from Brno made contacts with 28 countries through the RS satellites. He made some contacts with an erp of 5 Watts through RS5. He heard himself with 15 mW of erp through the now-nonfunctioning RS6.

According to unofficial information, new satellites RS9 and RS10 have been successfully examined in Kaluga near Moscow. They ought to be launched into space at the end of 1985. The satellites will be equipped with two converters each: 145/29 MHz and 21/29 MHz.

FEDERAL REPUBLIC OF GERMANY

Ralf Beyer DJ3NW
Opferkamp 14
3300 Braunschweig
Federal Republic of Germany

TRAINING FOR SPACELAB



On Saturday, August 17, 1985, a Cessna 207 aircraft took off from Cologne at 1105 hours local time with astronauts Ernst Messerschmid DG2KM and Reinhard Furrer DD6CF aboard, in preparation for their radio-amateur activity during Spacelab mission D1. The flight was oraganized by the German Aerospace Research Establishment (DFVLR) in cooperation with the MBB-ERNO company and the University of Bremen. The purpose of this flight was to test the 70-cm/2m transceiver that the astronauts would use aboard Spacelab and to get the astronauts familiar with the pileup to be expected during their space flight.

The flight took about 4 hours and 50 minutes and covered a large part of Germany. A route of 1100 kilometers was flown at an altitude of up to 11,000 feet. Practically everybody in Germany had a chance to get in contact with the aircraft, and even radio amateurs from Austria, Belgium, The Netherlands, and France were calling.

The astronauts used the call DF@LRK/air-mobile. This was the first radio-amateur activity from an aircraft to be authorized by the German FCC.

As usual, few radio amateurs were able to contact the astronauts directly. Many calls were taped, and it is hoped that the analysis of the 3-hour recordings will reveal about 300-400 callers. All stations identified will receive a QSL.

Messerschmid's comment, "They are calling faster than I can think!" showed that the astronauts really got a live demonstration of what may be expected during their space flight.

GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

The RAAG has a new address: Eleftherias Square 23-24, 105 53 Athens, Greece. Also there are two phone numbers: 3234527 and 3234624. Anyone who would like to be informed about reciprocal licensing, etc., is invited to write or phone.

Keep in mind that band allocations are not the same everywhere and information obtained from RAAG officials will prove to be very useful—especially when somebody wants to operate on the 2-meter band.

The annual meeting of IFATCA (air traffic controllers) was held last year in Athens from March 16-22. From the Royal Olympic Hotel (where the meeting took place), J4ATC was activated while the meeting was on, by W1BFA and PR@GJA. Although there was something missing in the call (should have been J41ATC), the station attracted a lot of DXers worldwide. I would like also to mention that Spyros Stefanou SV1IR was responsible for organizing this meeting; he did an excellent job.

A couple months ago, I was telling you about SV1JG, who took part in the *CQ* Worldwide WPX SSB contest. Today I feel proud to say that Greece, for the very first time in its radio history, has a continental winner in the single-operator allband category. Cliff, with his special call, J41JG, scored 1,667,576 and took first place in Europe. We hope next time Cliff will reach an even better position.

A new repeater will be active very soon from Enos Mountain on the Island of Kefalonia. The new repeater operates on repeater channel 2 (145.650/.050) and it is hoped that along with R8 it will cover all the Ionian sea area and the nearby mainland.

By the way, we are about to use up the string of two-letter callsign endings. If I am not mistaken, SV1ZZ has been issued already; we all expect to hear SV1ZZZ very soon.

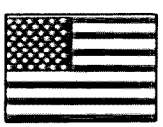
MT. ATHOS

I would like to discuss a situation which has given a lot of trouble to many SV DXers, including myself, and some RAAG officials, too. As most of you know, Greece supports four DXCC countries—Mainland (SV), Dodecanese (SV5), Crete Island (SV9), and Mt. Athos (SV/A). To really understand the story, you need to know that since Mt. Athos is a rare place

not only to operate from but even to visit, there is always big demand for a QSO with this DXCC country.

In order to go there, you need a proper license from the Greek PTT which is conditional and requires a written permission from the Holy Community to be valid. Because of a very complex situation, it is very difficult to get permission to operate from there (a signature is needed from every leader from the 20 monasteries). The last organized and valid operation was back in 1980, by SV1DC, SV1IW, and SV1JG.

Since then a lot of Greek and foreign amateurs have tried to get permission but with no luck. To be truthful, it looks like somebody told the Holy Community of Mt. Athos that the only purpose of expeditions is for green stamps and IRCs! Personally, I believe that this is the reason for no permits since then.



Despite this, in 1984, DJ5CQ went there without a written permit from the monks and operated for a while. In 1985, DL7FT did the same thing. He claimed that nobody had had a written permit for the last 10 years.

This was going too far. I sent the German league a letter of protest and a copy of the original license which I obtained in 1980 from the monks, along with translations in German and English.

A little after this, another presumptive DXer followed for another two-day show. (Remember him as KF1O/CE0X?) That was another suitor for Penelope's hand. (You will understand if you know Greek ancient history.)

The conclusion, after all these attempts, was to force the RAAG to write a letter to the Greek Ministry of Telecommunications and ask it not to issue a license for Mt. Athos anymore unless the applicant has a written permit from the monks in hand! Apart from that, I sent informative letters along with copies of my license and translations in English and German to all major DX Bulletins and magazines in an effort to prevent people from wasting their time and money.

Mt. Athos is a fine place to visit and a *real* fine spot to operate from. Will we ever be allowed back?

GUAM

Edward L. Campbell KB6DAW/KH2
300a Rendova
APO San Francisco 96334

HAFA ADAI FROM GUAM

Since propagation is poor and it looks like it is not going to get any better for a while, I thought it appropriate to bring up nets again—this time because there have been some good check-ins on them. And again, I will give times and frequencies that they are on.

To start off, I am a regular check-in for the 220 net with P29JS as net control. Lately, he has been on holiday and is back on Norfolk Island. His call now is VK9NS, but he will be returning soon. In his absence, VI2HD and I have been sharing the duties as net control.

Here are some of the check-ins that you will find on the net: VK9NL, FW8AF, 9M2MM, FT8XB, 3B8CA, YJ8RG, and 9V1TL, to name a few.

We have been blessed to have most of the DXpeditions check in with us, such as HC8E, 6Y5NR/KP1, and XF4—just to name a few. So if you hear of an expedition, you might look for it on the net.

Also, those that have propagation at 1100Z can look on 14.195 for RF@FWW every Wednesday, for his net. 5X5GK has tried to check in the last couple of weeks. Also 9N1RNK has been known to check in.

I have had a chat with XU1SS, and they are beginning to be up on the air a little more. You will find them around 1100Z at about 14.195. They do a lot of CW, so you might get a CW contact.

Have been trying to check in with the PHO net, but it is hard to get in with most of the antennas pointed into Europe. Now this is at 2100Z. I have had some luck turning my antenna over Europe and getting in that way. Now TZ6FE has been checking into the net quite often. So if you need that one, look for him at 2100Z. Maybe some day I will get to work him. So you might look into this part of the world from time to time—you might be surprised!

I did put out that I was trying to go to Johnston Island for a DXpedition, but it was turned down. I went on a DXpedition to KH9 Wake Island from October 22 until November 4. The calls were as follows:

- KB6DAW/KH9 for SSB contacts
- KA6DAW/NH9 for the *CQ* WW Contest only
- NY6M/AH9 for CW contacts

NY6M is now on KH2, and his name is Gary Dein. And he is a good CW man.

All QSLs should go to the address above.

Well, more next time. 73 and hafa adai from Guam Island, where America's day begins!

HONG KONG

P. J. Weaver VS6CT
10A Bonaventure House
91 Leighton Road
Hong Kong

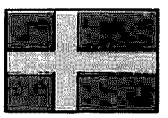
Sunday, June 2nd, dawned bright and clear with a 15-knot wind from the east. A Cessna 172 was airborne from Kaitak at 0830 to reconnoiter the course to a rock called Pedro Blanco, 50 miles to the east of Hong Kong. Hong Kong's first offshore power-boat race from a position south of Aberdeen out to Pedro Blanco Rock and return, a distance of 120 miles, was scheduled to start at noon.

There were ten power boats entered for the race, the largest being a Cigarette 27′ and the smallest a Fletcher 21′ with two 120-hp outboards. For safety purposes, mark boats were to be established every ten miles of the course. These boats were a real mixture: from the largest, a Techma 68′, down to a Bertram 38′. All were well-found boats, and on each would be a radio amateur to handle communications, ship to ship and ship to aircraft, operating on channel 10, 156.5 MHz; all the hams were to keep in touch through the repeater on 145.650 MHz.

At 0900, the first mark boat started eastward, and by 1030 hours, it reported seas of up to 6 feet at times. When the aircraft had made its run the tide and wind had been running together, but with the turn of the tide at 0900, the wind against the fast ebb produced a short steep sea which the mark boats found difficult to cope with. By 1100, it was apparent that the mark boats were not able to get to their assigned positions.

The committee put on their thinking caps, and at 1130, having recalled the mark boats through ham radio, changed the course to run inside Hong Kong waters: It would be three times around a triangle from Lamma Island, just south of Aberdeen, to the Soko Islands, and thence to Potoi Island to make up to the original 120 miles.

It was still very bumpy going upwind, and Ramesh Murjani, the organizer, in his Cigarette 27′ was the only finisher on a circuit shortened to two laps (80 miles).



Our thanks to Hong Kong hams VS6IC, VS6XPQ, VS6DK, VS6XPZ, VS6XPT, VS6DM, VS6GW, VS6CT, and Macau ham XX9WW, without whose assistance even the abbreviated race could not have been held.

In my last report I mentioned that Hong Kong was following the United Kingdom with a class B license for 30 MHz and above. At this time there are over 150 class B licensees.

A new club has been formed within the Hong Kong Telephone Company's Sports and Social Association due to the enthusiasm of one ham, Marvin Chan King Tung VS6XNR, to whom full credit must go, as without his drive and interest the club could never have started. They now have over 350 members, all employees of the Telephone Company, keen to pass the necessary examination and get their licenses. They will shortly establish a club station and be very active with their assigned callsign of VS6TS; they also have their own club repeater on two meters.

With the increase in local hams there is a need for more repeaters, and the current two could well be expanded to four by the end of this year.

Just a brief reminder if you intend to visit Hong Kong and would like to operate. A visitor's license is readily available, so bring a copy of your home license with you next time you visit. The callsign assigned is your home call /VS6. Call me at home on 5-772313, or Ed Nance VS6DX on 5-231358, for full details and information about what's happening in Hong Kong when you get here.

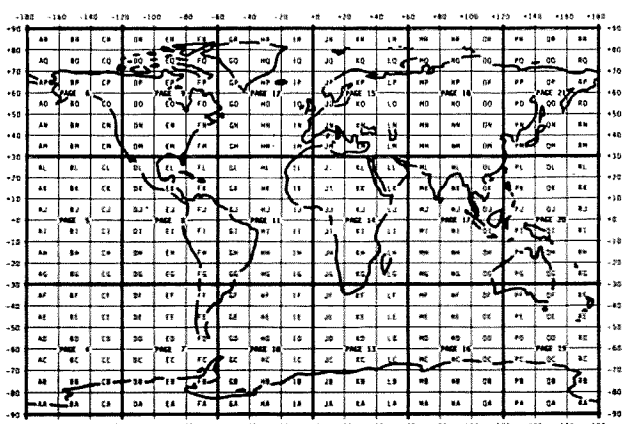
WORLDWIDE QTH LOCATOR

The origin for the QTH-locator (grid) system used by the European VHF/UHF enthusiasts was in the 1950s. For many VHFers, chasing QTH locators (such as IT50d, giving fairly good accuracy on the position of the QTH) has become an obsession comparable with the most avid HF-band chasers of new DXCC countries.



The original QTH-locator system had its drawbacks. It was designed for Europe, and if extended to cover worldwide, the system had to repeat itself, i.e., the same QTH-locator designation could mean quite different locations.

The increasing interest in using the QTH locators, not only as needed during VHF contests, but also because of the increased coverage of the world's surface that VHF/UHF operators have achieved, made it obvious in the mid 70s that a worldwide system should be designed.

Maidenhead Locator System

The European VHF managers held a meeting in Maidenhead, United Kingdom, in April, 1980, where Folke Rosvall SM5AGM presented the more than 20 proposals for a new locator system which had been received. The VHF managers found that the system proposed by G4ANB with the modification by SM5AGM should be put forward to IARU for adoption.

Folke SM5AGM started the work on an international scale for a worldwide locator system by presenting his ideas at the VHF-manager meeting held in Amsterdam, Netherlands, in 1976. In October of

World map of the fields.

Folke Rosvall SM5AGM.

AMATEUR TELEVISION

NEW 70 CM ATV TRANSCEIVER

ALL YOU NEED IN ONE BOX

$299 delivered
TC70-1

- **FULL COLOR, SOUND, & LIVE ACTION** just like broadcast TV. Get on this exciting amateur video mode at our affordable ready to go price.
- **WHAT IS REQUIRED FOR A COMPLETE OPERATING SYSTEM?** The TC70-1s downconverter outputs to any TV on ch 3 for receiving. Connect a good 70 cm antenna and low loss coax. Plug in any composite video source you want to transmit: Camera, VCR, computer, etc. Plug in any low Z dynamic mic or use color camera mic for Standard 4.5 mHz TV sound. Connect to 13.8 vdc for base, mobile, or portable. See chapt. 20 1985 ARRL Handbook. That's it!
- **WHAT CAN YOU DO WITH THE TC70-1 ATV TRANCEIVER?** Show the shack, projects, computer program listings, home video tapes, repeat Space Shuttle audio and video if you have a TVRO, repeat SSTV or RTTY, Weather Radar, do public service events such as parades, marathons, races, CAP searches and rescues . . . the list goes on. DX depends on antennas and terrain, typically 1 to 40 miles. We have video compensated RF linear amps for 20 ($119) or 50 ($189) watts pep for greater DX.
- **FEATURES:** Small 7x7x2.5". Push to Look (PTL) T/R switching. GaAsfet downconverter tunes whole 420-450 mHz band. Two switch selected video & audio inputs . . . RCA phone jacks and 10 pin color camera jack. Xmit video monitor output. Over 1 watt pep RF output on one or two (add $15) selected crystal controlled frequencies. 439.25, 434.0, or 426.25 mHz.

CALL OR WRITE FOR OUR CATALOG for more info or who is on in your area. We stock antennas, modules, and everything you need on ATV.

TERMS: Visa, MC, or cash only. UPS CODs by phone or mail. Checks must clear bank before shipment. Price includes UPS surface shipping in cont. USA; others add 3%. Transmitting equipment sold only to licensed Tech class or higher amateurs, verifiable in 1985 call book or copy of new license.

have to agree with them. After all, Chet's *Computer Trader Magazine* stands to increase its circulation due to the heightened (and free) publicity, and the equipment manufacturers also get to look good by donating prizes. In the end, the contest is just a way of using ham radio to increase sales.

An Answer?

You might have noticed that I applied a general rule of thumb in each of the four instances to decide whether it constituted commercialism or not. You can call this Donham's Law if you like: *If the action could eventually result in money exchanging hands, it is a definite no-no.* The solution to the problem of commercialism in our hobby is to place in the amateur rules this strict definition of business communications.

The new rule would not differentiate between commercial ventures and nonprofit organizations (note that TAPR is nonprofit). The sole criterion would be the exchange of funds. No exceptions. With such a definition in place, much of the junk that we hear on the bands would disappear—then maybe these bells would stop ringing in my head.

Perry Donham

HAM HELP

I am looking for automobile and motorcycle amateur-radio callsign license plates for my collection. I will pay postage. I also have a few plates to trade.

W. C. Spenn KD5AK
Box 33081
San Antonio TX 78265

I'm looking for a computer interface for a Commodore-64 like the MFJ-1226 or the MFJ-1228. Also, I need a manual for a Heathkit HW-7.

Edward Turner
4376 W. Coolidge Rd.
Coleman MI 48618

1979 Folke proposed a system with 20° x 10° units, 2° x 1° smaller units, and 5' x 3' smallest units. Quite independently, G5ANB had designed a similar system.

The locator consists of two letters (the field) followed by two numbers, the square in the field, and two letters giving the position within the small square in the field. This system gives the position of the QTH with an accuracy of better than four kilometers (2.5 miles). On the HF bands and for the Field Award, it is enough to know the large unit, the field, i.e., the two first letters.

Folke has been the driving force for this worldwide locator system. Without his persistent work and refusal to let the opposition kill this effort, a worldwide locator system would probably still be far in the future.

The Field Award—
A New Challenge

Now it is time to start collecting fields for the new Field Award issued by SSA, the Swedish National Amateur Radio Organization. The Maidenhead Locator System has been adopted by all three IARU Regions and has worldwide coverage.

Altogether there are 324 fields, and you surely will not work all of them in a year or two, if ever. 262 fields are covered by some kind of land, 8 fields are covered by permanent ice without land, and 54 fields are covered by open sea. Stations operating /MM and polar expeditions will be needed for working all fields!

What is my Locator or Field?

The *World Atlas* containing all 32,400 Maidenhead locator squares, produced by SM5AGM, will readily give you most fields by knowing the QTH of the station you have worked. If you want to have your own full locator, the booklet includes a computer program for the necessary calculations. You must find out your longitude and latitude in degrees and minutes.

If you have any questions on either the Field Award or the *World Atlas*, write to The Field Award Manager, SSA, Ostmarksgatan 43, S-123 42 Farsta, Sweden. Please include an SASE or SAE plus IRCs.

Any questions about the locator system, including a request for finding out your own locator (do not forget to include your longitude and latitude) can be sent to Folke Rosvall SM5AGM, VasterskarsrIngen 50, S-184 00 Akersberga, Sweden. Please include an SASE or SAE plus an appropriate number of IRCs to cover his expenses. Folke compiles a "Worked Locator Field List" on a quarterly basis. Why don't you send your score per band to Folke to be included in the list!

Whenever working a station on any band, always exchange Maidenhead locators or at least the two letters for the field.

SATELLITES

USING THE AO-10 APOGEE PREDICTIONS

Apogee predictions for the month of January are provided for three sections of the United States: Washington DC at 39N 77W, Kansas at 39N 95W, and California at 38N 122W. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

Atco NJ 08004

WORLD SSB CHAMPIONSHIPS

Announcing the January Classics—the 1986 running of the World SSB Championships! The first and only contests of their kind, these five (5) individual single-band events are world-renowned and amongst the most challenging events on the bands today. Winners of each contest determine the World Champion for 15-, 20-, 40-, 75-, and 160-meter single sideband:

January 11, 1986
0000-2400 UTC
5th 40-Meter World SSB Championship

January 12, 1986
0000-2400 UTC
5th 75-Meter World SSB Championship

0000 UTC January 18, 1986,
through 2400 UTC January 19, 1986
7th 160-Meter World SSB Championship

January 25, 1986
0000-2400 UTC
2nd 15-Meter World SSB Championship

January 26, 1986
0000-2400 UTC
2nd 20-Meter World SSB Championship

Stations may be worked only *once per event*. All contacts must be two-way SSB. All stations, regardless of operating class, may operate the entire contest period.

OPERATOR CLASS:

(a) single operator, single transmitter, SSB only; (b) multi-operator, single transmitter, SSB only.

EXCHANGE:

Stations within the 48 continental US states and 13 Canadian provinces or territories transmit RS report and state, province, or territory. All others, including Alaska and Hawaii, transmit RS report and ARRL DXCC country.

QSO POINTS:

5 QSO points for contacts *within* your own *continent*.

10 QSO points for contacts *outside* your own *continent*.

MULTIPLIERS:

1 multiplier point is earned for each continental US state (48 max.), Canadian province or territory (13 max.), or ARRL DXCC country (excluding the United States and Canada).

SUGGESTED FREQUENCIES:

21.250-21.350; 14.175-14.250; 7.050-7.080 (DX); 7.175-7.250 (W/VE); 3.760-3.790; 3.805-3.875; 1.830-1.850; 1.855-1.900 MHz.

DX WINDOW:

For the purpose of this event, DX window frequencies are reserved for *split-band operation only*. W/VE stations are *not* to transmit in the window at all. DX stations *may* transmit but *must* receive outside the window frequencies. DX windows include 7.080-7.090, 3.790-3.805, 1.825-1.830, 1.850-1.855, and 1.907-1.913 MHz.

FINAL SCORE:

Total QSO points × multiplier points = claimed score.

ENTRIES:

Entries *must* include (1) a contest log, (2) a dupe sheet for 100 or more contacts, (3) a list of multipliers, and (4) a summary sheet as outlined below. Be sure to *include* your soapbox comments and a black and white *photo* for possible publication.

SUMMARY SHEET:

Summary sheets must contain (1) contest callsign, (2) your state, province, territory, or ARRL DXCC country, (3) station owner's name and mailing address, (4) a list of station equipment and antenna(s), (5) the operator class, (6) total QSOs, (7) total QSO points earned, (8) total US states worked, (9) Canadian provinces and territories worked, (10) the total of ARRL DXCC countries worked, (11) total multiplier points, and (12) your claimed contest score.

ENTRY DEADLINE:

Entries should be mailed to the appropriate contest chairman listed below. Entries must be *POSTMARKED NO LATER THAN FEBRUARY 20, 1986*. Late entries will be registered as check logs.

DISQUALIFICATION:

Contestants may be disqualified if they run illegal power, cause deliberate interference, fail to comply with the rules for the DX window, attempt to achieve a scoring advantage, or if duplicate contacts not cancelled exceed more than 3% of the total contacts made. Decisions of the contest committee are final. Disqualified stations will be barred from these events for one year thereafter.

PENALTIES:

A penalty of 100 QSO points will be assessed for each duplicate contact counted in a contestant's claimed score.

AWARDS:

A minimum of 100 QSOs must be worked in an event to be eligible for a contest award. Plaques will be issued to the World Championship Stations. Awards will be issued in each operator class, in each continental US state, Canadian province and territory, and ARRL DXCC country represented.

RULES AND FORMS:

Contestants are encouraged to use official contest forms. To obtain your own copy of the rules and each contest form, send an *SASE* to: *Contest Rules and Forms, Billy Maddox KA6JJK/3, 1162 Bayview Vista Drive, Annapolis MD 21401.*

ARRL STRAIGHT KEY NIGHT
Starts: 0000 UTC January 1
Ends: 2400 UTC January 1

Sponsored by the ARRL, this is a friendly meeting on the air using straight keys. Suggested areas of operation on 80, 40, and 20 meters are 60 to 80 kHz from the lower band edges and 10 kHz from the lower Novice band edges. When participating, use "SKN" instead of RST preceding the three-digit report to clue in passersby. Following SKN, send a list of stations worked plus your vote for best fist heard during the period. Note, your vote does not have to be from the stations worked; it can be another station you've heard working SKN. This is not a contest, so quick contest-like exchanges are discouraged. Include a vote for the most interesting QSO besides your best-fist vote

BADGER STATE
Smoke Signals
Serving Amateur Radio in Wisconsin

NEWSLETTER OF THE MONTH

Imagine our surprise when we opened the latest *Badger State Smoke Signals*—and a pair of 3-D glasses fell out! The glasses, donated by a local television station, allowed us to see the Yellow Thunder (Wisconsin) ARC's Field Day operation *as if we were actually there!* To our knowledge this is the first time that 3-D pictures have appeared in a radio club newsletter.

But the flashy pictures are not the only reason that *Smoke Signals* is this month's winner. We've been consistently impressed by the quality and breadth of the coverage given amateur radio by Editor Ken Ebneter K9ZZ. *Smoke Signals* is a publication that serves all of the radio clubs in Wisconsin, so Ken obviously has a great deal of information to draw from. Each issue we've seen has been lively reading, and we'd like to congratulate Ken and his crew for putting out such a great publication.

To enter your club's newsletter in 73's Newsletter of the Month Contest, send it to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

and mail a report to ARRL Headquarters, Newington CT 06111 by January 10, 1986.

ARRL MIDNIGHT SPECIAL
Starts: 0400 UTC January 5
Ends: 0600 UTC January 5

During the first hour use 80 CW; during the second hour use 75 phone. Work stations once on each mode. Suggested frequencies are 3540-3570 and 3855-3895. Exchange 3-digit consecutive serial number beginning with 001 plus name. Final score equals total number of QSOs worked with no multiplier. Mail entries by February 3, 1986, to ARRL Headquarters, Newington CT 06111. Top scores will be listed in *QST*.

HUNTING LIONS IN THE AIR CONTEST
Starts: 0000 UTC January 11
Ends: 1200 UTC January 12

The contest is sponsored by Lions Clubs International and coordinated by Lions Club Rio de Janeiro Arpoador—Brazil. Participation in the contest is open to all duly-licensed radio operators, Lion and non-Lion. There are two modes: phone and CW. Participation in both modes is allowed but points are counted separately. All amateur stations participating must operate within their licensing regulation. Separate categories will exist for single-operator and radio clubs/societies. Multi-operators may participate as long as they do not operate simultaneously with the same prefix. However, each callsign used must be listed on the log.

Use 80, 40, 20, 15, and 10 meters. Associates of the Lions Club of Rio de Janeiro Arpoador will operate mainly within the first 50 kHz of each band and around 14.270, 21.270, and 28.550. Only one QSO with the same station on each band and each mode may be counted. Remember that phone and CW are counted separately!

EXCHANGE:

RS(T) and sequential QSO number. When contacts are made with Lions, Leos, or Lionesses, the name of the club contacted should be clearly identified.

SCORING:

QSOs within the same continent count 1 point, while those between different continents count 3 points. Score 10 extra bonus points for each QSO with a member of a Lion, Lioness, or Leo Club from a different country or 5 points within the same country. Score 20 bonus points for a QSO with a member of the Lions Club Rio de Janeiro Arpoador or for each QSO with a member of the Melvin Jones Memorial Radio Club of the United States. Score 25 extra points if contact is made with the Arpoador official station with callsign PY1LCA.

Contacts between Brazilian stations and members of the Arpoador club, as well as North American stations and Melvin Jones Memorial Radio Club, will count only 5 extra points. Contacts between Brazilian stations and the Arpoador official station (PY1LCA) will count ony 10 extra points. Contacts between members of the Arpoador club, as well as contacts between members of the Melvin Jones Memorial Radio Club, will not count any bonus points.

AWARDS:

For both categories, the Lions Club International will present trophies for first, second, and third place on both modes. For single operators, fourth through tenth places will receive plaques. In addition, each log sent by participants with a minimum of 15 contacts will receive a special certificate.

ENTRIES:

Keep a separate log for each mode and clearly indicate the operating category. Each particpant will note in the logs the callsign and information exchanged. Confirmation of contacts will be made by comparing the logs of participants. Participants should send their logs by air mail not later than February 15, 1986, to: Contest Committee, Rio de Janeiro Arpoador Lions Club, Rua Sao Francisco Xavier No. 246, Apt. 407, 20551, Rio de Janeiro, RJ, Brazil.

MICHIGAN QRP CLUB CW CONTEST
Starts: 1500 UTC January 11
Ends: 1500 UTC January 12

The contest is open to all amateurs and all are eligible for the awards. This is a CW-only, allband QRP contest. Use all bands from 160 to 10 meters, excluding WARC bands. Each station will be competing within his own state, province, or country in one of the following categories: (1) one Watt or less output power; (2) five Watts or less output power; (3) over five Watts output power.

EXCHANGE:

RST, state, province, or country, plus power output.

SCORING:

Each contest is worth one QSO point. Multiply by the number of states, provinces, and countries worked per band for total points. If operating 100%-natural or battery emergency power, use a bonus multiplier of 1.5 times total points.

AWARDS:

Certificates will be awarded to the highest-scoring station in each state, province, and country.

ENTRIES:

Log information must include: full log data with a separate log for each band, name and address, equipment used, and power output. Logs must be received no later than six weeks after the end of the contest. Please include an SASE or two IRCs for contest results if desired. Send all logs to: Chris Hethorn KM8X, 6818 Meese Dr., Lansing MI 48910.

ARRL VHF SWEEPSTAKES
Starts: 1900 UTC January 11
Ends: 0400 UTC January 13

Sponsored by the ARRL, this is the 39th annual running of this event. As usual, check *QST* for any last-minute rule changes. The object of this contest is to work as many amateurs in as many 2-by-1-degree grid squares as possible, using authorized amateur frequencies above 50 MHz. Foreign stations may only work W/VE amateurs.

Operating categories include: (A) single operator, single band; (B) single operator, allband; (C) multi-operator. Single-band entries may submit QSOs made on other bands for ARRL-affiliated club competition credit. Multi-operator stations must have all equipment and antennas located within a 300-meter-diameter circle.

Use of repeater frequencies or retransmission of either signal is not permitted. This also includes soliciting contacts via 2-meter repeaters or on repeater frequencies. Use of national simplex frequency, 146.52 MHz, or immediate adjacent guard frequencies is likewise prohibited. However, there are no restrictions on the use of 223.50 MHz.

Only recognized simplex frequencies may be used, such as 144.90 to 145.10; 146.49/.55/.58; 147.42/.45/.48/.51/.54/.57 MHz on 2-meters. Local-option simplex channels and frequencies adjacent to these frequencies that do not violate the intent of the above rules or the spirit and intent of the band plans may be used for contest purposes.

Stations may be worked only once per band from any given grid square for credit, regardless of mode. Stations changing grid squares must submit a separate entry for each grid square from which they operate. Crossband QSOs do not count.

Any transmitter used to contact one or more stations may not be used under any other call during the contest period, with the exception of family stations where more than one call is assigned to one location by FCC/DOC. Only one signal per band is permitted at any given time, regardless of mode. While no minimum distance is specified for contacts, equipment should be capable of real communications over at least 1 km. Above 300 GHz, contacts are permitted for contest credit only between licensed amateurs of Technician class or higher using coherent radiation (laser) and employing at least one stage of electronic detection on receive.

Multi-operator stations may not include QSOs with their own operators except on frequencies higher than 2.3 GHz. Even then, a completely different station must exist for each QSO made under these conditions.

EXCHANGE:

Grid-square locator (see the January, 1983, *QST*, page 49); signal reports are optional. Partial QSOs do not count. Both callsigns, the full exchange, and acknowledgement must be sent and received for credit. Any station located precisely on a dividing line between grid squares must select only one as the location for exchange purposes. A different grid square multiplier cannot be given out without moving the complete station at least 100 meters.

SCORING:

Count one point for complete two-way QSOs on 50 and 144 MHz, two points on 220 or 432 MHz, four points on 902 and 1296 MHz, and eight points on 2.3 GHz or higher. The multiplier is the total number of different grid squares worked per band. Final score is total QSO points times total number of multipliers.

AWARDS:

Suitable awards will be presented to the top-scoring single operator in each ARRL section and on each band in each section for single-band entries. The top multi-operator awards will be made for top scores in each ARRL section where significant effort or competition is evidenced. Multi-operator entries are not eligible for single-band awards.

ARRL-affiliated clubs can compete for gavels on three levels: unlimited, medium, and local. Details are listed in the January issue of *QST*.

ENTRIES:

Logs must indicate time in UTC, bands, calls, and complete exchanges. Multipliers should be numbered clearly the first time they are worked. Entries with more than 200 total QSOs must include cross-check sheets. All entries must be postmarked no later than 30 days after the contest and mailed to the ARRL, Newington CT 06111. Use ARRL VHF SS forms or a reasonable facsimile. Each entrant agrees to be bound by the provisions of the rules, the regulations of his or her licensing authority, and the decisions of the ARRL Awards Committee. Disqualifications will be made for excess duplicates and call-sign or exchange errors.

NORTH DAKOTA QSO PARTY
0000-0800 UTC January 18
1600-2400 UTC January 18
0800-1600 UTC January 19

Sponsored by the Red River Radio Association, contestants may work stations once per band and mode.

EXCHANGE:

Signal report and QTH (county for ND stations; state, province, or country for others).

SCORING:

10 points per phone contact, 20 points per CW contact, and 50 points per RTTY contact. ND stations add 250 bonus points for working 5 Novices. Multiplier for ND stations is number of states/provinces/countries worked. Multiplier for non-ND stations is the number of ND counties worked (53 maximum).

FREQUENCIES:

Phone—1.810, 3.905, 7.280, 14.295, 21.380, and 28.500; CW—1.810, 3.540, and 35 kHz up from the band edges; Novice—25 kHz up from the band edges.

ENTRIES:

Mail logs by February 28, 1986, to Mike Beaton KD0A, 2267 Flickertail Drive, Fargo ND 58103. Include a large SASE for results.

RATS NEST AND CROOKED STICK VI ANTENNA EXPERIMENTER'S CONTEST SPRINT
Starts: 2300 UTC January 18
Ends: 0400 UTC January 19

Sponsored by the Issaquah Amateur Radio Club, the object of this contest is to accumulate QSO points by making contacts using a home-brew wire antenna. The antenna may be in any configuration, as long as it includes the use of a crooked-stick support. Maximum transmitting power is 250 Watts dc input.

EXCHANGE:

Name, QTH, type of antenna, and indicate if IARC member.

FREQUENCIES:

CW—7.050 to 7.150; SSB—7.225 to 7.300.

SCORING:

CW QSOs count 5 points, phone 2 points. Each new state, province, or country counts as a multiplier of two. To encourage "Elmering" and participation of everyone interested in amateur radio, new individuals and old-timers alike, the following bonus has been established: Contacts made with an apprentice's assistance, add 2 points. Contacts made by an apprentice (minor coaching allowed) add 5 points.

AWARDS:

Best CW, SSB, Novice/Tech; best with Rats Nest antenna; best Elmer. There is also a personalized Rat Catcher certificate for contacting three or more IARC members.

ENTRIES:

Submit entries by February 1, 1986. Include summary sheet with points per mode, bonus points earned, total points

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, 80 Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

earned, name, call, address, complete description of antenna and equipment used, license class, and copy of log sheet. Logs to include time, call, frequency, mode, and exchange. Clearly mark three IARC member contacts to qualify for Rat Catcher Award. Send all correspondence and entries to the Issaquah Amateur Radio Club, c/o Steve Pack WB7VAS, 4609 158th Ave. SE, Bellevue WA 98006.

ARRL NOVICE ROUNDUP
Starts: 0001 UTC January 25
Ends: 2359 UTC February 2

The object of this ARRL-sponsored contest is for Novice and Technician operators in the US to exchange QSO information with as many stations as possible on the 80-, 40-, 15-, and 10-meter Novice/Technician bands. Others work Novices and Technicians only. All stations must operate no more than 30 hours during the contest period. Off periods must be at least 15 minutes; listening time counts as operating time. Times on and off must be indicated in your log.

Operating categories include: (A) single operator—one person performs all transmitting, receiving, and logging functions; (B) multi-operator, single transmitter only—those obtaining any form of assistance, such as relief operators or logging.

EXCHANGE:

Signal report and ARRL section or DX country. Novices should send /N and Technicians /T after their callsigns so others will know their license class.

SCORING:

Count one point for each complete two-way QSO. Work each station once, regardless of band. No crossband contacts are permitted. Multiplier is the number of ARRL sections plus VE8/VY1 and foreign countries. Additional points can be earned if you have qualified for an ARRL Code Proficiency certificate (not FCC). CP credit equals the speed in words per minute indicated on the latest certificate or sticker held by the entrant. Final score is computed by adding your Code Proficiency credit to your total number of QSO points. Then multiply that by your ARRL section/country total for your final score.

AWARDS:

Certificates will go to the top Novice and Technician in each ARRL section and each single-operator Novice or Technician who submits a valid entry with 200 or more QSOs. Multi-operator or General-class licensees and above are not eligible for awards.

ENTRIES:

Contest forms are available from the ARRL for an SASE. Official forms are recommended. Any entry making more than 200 QSOs must submit duplicate-checking sheets with alphabetical listings of stations worked. Incomplete or late entries will be classified as check logs. Logs should include dates, QSO times, on and off times, complete exchange sent and received, and band. Postmark entries within 30 days after the contest, addressed to the ARRL, Newington CT 06111. Each entrant agrees to be bound by the provisions as well as the intent of the rules, regulations of his/her licensing authority, and the decisions of the ARRL Awards Committee. Usual ARRL disqualification rules apply.

MICHIGAN YL QSO PARTY
Starts: 1800 UTC January 25
Ends: 1800 UTC January 26

Sponsored by The Auto State Young Ladies (TASYLs). No crossband, net, or repeater QSOs are allowed. Each station can be contacted only once.

EXCHANGE:

RS(T), QTH, and TASYL# (for members).

SCORING:

Score one point per QSO and multiply by 2 if on CW. Multiply again by 2 if TASYL member. Multiply QSO points by number of different ARRL sections and DX countries worked.

ENTRIES:

Send logs to TASYL President Verline Ferris KI8V, 308 E. Harry, Hazel Park MI 48030. Entries must be received by February 28, 1986.

The TASYL Certificate may also be earned during the QSO Party for working TASYL members. Charter Members 1 through 50 count 2 points, while all other members count 1 point. MI stations need 15 points, VE and other US stations need 10 points, and DX or VHF stations need 6 points. To apply for the award send a signed and dated log showing the date and time of contact, callsigns, frequency, RST, and TASYL number. Certification giving date and QTH must be on the original application and signed by one of the following: 2 licensed amateurs, General-class or higher (non-family), one official of a recognized club, or a notary public. Include $1.00 to cover mailing costs, etc., and submit applications to Elaine Matyjaszek KA8KAK, 1127 Hillcrest Dr., Boon MI 49618.

CLASSIC RADIO EXCHANGE
Starts: 2100 UTC January 26
Ends: 0400 UTC January 27

The purpose of this event is to restore, operate, and enjoy older equipment. A classic radio is one which was built since 1945 which is at least ten years old. The same station may be worked with different equipment combinations on each band on each mode. Non-contestants may be worked for credit.

EXCHANGE:

Name, RST, state/province/country, receiver and transmitter type (home-brew send PA tube, i.e., "807"), and any other points of interest.

FREQUENCIES:

CW—up 60 kHz from the low band edges; phone—3.910, 7.280, 14.280, 21.380, 28.580; Novice/Technician—3.720, 7.120, 28.120.

SCORING:

Multiply total QSOs (all bands and all equipment combinations used) by the total number of different receivers, transmitters, and states/provinces/countries worked on each band and mode. Multiply that total by your classic multiplier (total years old of all receivers and transmitters used—three QSOs minimum per unit; if equipment is a transceiver, multiply age by two).

ENTRIES:

Send logs, comments, anecdotes, etc., to Stu Stephens K8SJ, 1407 Hollyrood Road, Sandusky OH 44870. Include an SASE for the *Classic Radio Newsletter* (published twice each year).

VHF POWER AMP

AM-6154/GRT (ITT 3211) 116-149.95 MHz RF amp, 50 watt output from 4-10 W input using Amperex DX393 or Eimac X651Z/8930; has silver-plated cavity in removable drawer. PA tube checked prior to shipment, but not guaranteed for use in modified amps. Requires 115/230 VAC & 20 VDC; 7x19.5x17, 75 lbs sh (UPS in 2 pkgs.). Used, not tested-good condition **$209.50**

CU-872 HF ANTENNA COUPLER for up to eight 2-32 MHz receivers; 70 ohm output, N connections, test meter, and 20/6922 tubes. 7×9×16.5, 40 lbs sh. Used. **$49.50**

ZM-11 UNIVERSAL BRIDGE, measures 10 pf-1100 mf Capacitance, 0.1 mH-110 H Inductance, Insulation DC Resistance, Transformer Turns Ratio, DC Leakage, Dissipation, and Q Storage. 115 VAC 60 Hz; 5.8×9×9.8, 18 lbs sh. Used-checked. ..... **$115.00**; Manual partial repro. **$8.50**

Prices F.O.B. Lima, O. • VISA, MASTERCARD Accepted.

WHAT?

News from W1XU

As I write, Halley's Comet has recently made its once-in-a-lifetime reappearance in the night sky, and a lot of extra attention by astronomers, photographers, and even the man in the street is being focused on the heavens to catch a glimpse of this infrequent visitor to our solar system. It seems appropriate, therefore, to talk a little about the solar system and its relationship to amateur radio.

Hams aren't strangers to the space surrounding the sun and planets, for we've bounced signals off the moon, relayed messages by satellite, and propagated radio waves through Earth's ionosphere. For years we've known about the sunspot cycle and its effect on radio propagation at high frequencies, and we've been able to calculate seasonal and daily variations in the MUF which affect the likelihood of one band or another being open between two locations on Earth. Although necessary, such information is by no means sufficient, because it does not take into account the day-by-day condition of Earth's magnetic field which so drastically influences our ability to communicate.

The late John Nelson, who prepared propagation forecasts for *73* for so many years, was among the first to suspect (and finally utilize) the surprising influence of planetary positions on propagation to make his astonishingly 80%-accurate predictions. Because Earth is bathed by solar radiation and, in fact, can be considered to be within the solarsphere, ionospheric propagation on Earth is complicated by the extremely variable and often unpredictable nature of the sun, whose nuances of behavior have such a powerful effect on communications. Sunspots, solar flares, coronal holes, and other major events on the sun have long been associated with radio propagation and, in recent years, have been reported regularly by the Space Environment Services Center of Boulder, Colorado, in its weekly report, *Preliminary Report and Forecast of Solar Geophysical Data*. This magnificent and extremely valuable publication is available to anyone for the asking; it catalogs hourly solar events over a period of days. You can find such phenomena as 2800-MHz solar flux, sunspot count, A and K magnetic indexes, flares, and other information of vital interest to radio communicators.

For the past eight years I have kept almost daily records of solar events on a chart which also includes the planetary alignments. Not long after I began recording, I noticed that certain alignments seemed to have a marked effect on propagation. In particular, sharp fluctuations and sudden jumps in the magnetic-field index appeared to be associated with specific alignments, particularly quadratures and inferior/superior conjunctions between some of the planets and the sun. Of even greater interest because of its implications, there seemed to be a relationship between the position of the planets and major or catastrophic events on Earth such as volcanic eruptions, earthquakes, and even hurricanes. Now, I use charts prepared several months in advance to produce the monthly propagation forecasts in *73*.

I feel obliged, in all honesty, to remark that I have not proved anything, although I think I have found some interesting and potentially important correlations. There is no consensus among observers and scientists about planetary influences; in fact, most pooh-pooh them. Nevertheless, it seems possible to me that the planets may "modulate" the sun's electromagnetic field in a manner similar to the moon "modulating" Earth's gravitational field and affecting the tides.

Perhaps it would be of interest to follow an example of the charting process from which I make the predictions. Using *The Astronomical Almanac* (available from the US Government Printing Office), I make a simple graph which has degrees on its horizontal baseline and days of the month along its vertical left margin. The degrees run from 0-90, 90-180, 180-270, and 270-360, with each 90-degree range lying exactly underneath its neighbor. In this way I can obtain quadratures (90-degree relationships), inferior conjunctions (180-degree relationships), and superior conjunctions (0-degree relationships). I then read the position of each planet from the *Almanac* and plot its location in heliocentric degrees along the baseline for the first day of the month and along the top line for the last day of the month. It is then a simple matter to connect these locations with a straight line. Where planetary position lines cross one another, there is an alignment, and their angular relationship is obvious.

Next, I take the day of each alignment and place it on another (master) chart as a vertical line according to the day on which it will occur. The days run along the abscissa on this chart, with ordinates representing values of solar flux, magnetic-field index, and the like. The master chart is then filled in with the data as the information becomes available from WWV or from the previously-mentioned *Solar Geophysical Data*. I plot the dates of moon perigee and full moon as well. After several weeks of plotting the data points and connecting them with the various colored lines, one can see relationships between solar (and Earth) events as they coincide with the planetary alignments. I have to admit that much of this can be (and probably has been) computerized to reduce the amount of time required to prepare the charts.

The chart becomes a running record of events versus planetary positions, and it is fun to see the relationships develop with time. For example, the eruption of the volcano in Colombia on November 13th coincided with a 90-degree alignment of Earth and Jupiter, an inferior conjunction of Earth and Mercury, a 90-degree alignment of Mercury and Uranus, and a 90-degree alignment of Mars and Uranus. Interestingly, the sunspot count jumped from zero on the 3rd to 50 on the 13th and

New Sats

THIS MONTH should see the launch of two new Soviet amateur satellites, RS-9 and RS-10. Both will be in orbits similar to the current set of RS satellites, with a period of about 2 hours. RS-9 will carry only a Mode A transponder (2m up, 10m down). RS-10 will have three transponders: Mode A, Mode K (15m up, 10m down), and Mode T (15m up, 2m down). The 2m beacon will be at 145.557 MHz. Also expected is the ejection of ISKRA-4 from the space station Salyut-7; the satellite will carry a Mode K transponder and will circle the earth every 92 minutes for just a few months.

Ham Stats

THE LATEST FIGURES released by the International Amateur Radio Union (IARU) concerning the number of licensed amateurs in the world are very interesting. In order of ham population, the top ten countries are: Japan (no surprise there!), the United States, the USSR, Brazil, the United Kingdom, the Federal Republic of Germany, Italy, Spain, Argentina, and Canada. I was really *amazed* that Yugoslavia or Czechoslovakia wasn't right up there—seems like every time I tune across 20 meters the band is just *full* of OKs and YUs! When ranked by the number of hams who are members of their national society, the list looks like this: the Federal Republic of Germany on top with 77%, the United Kingdom in second place with 51%, Spain right on the UK's heels with 50%, Italy with 37%, and the United States in fifth place with only 27%. All told there are 1,511,000 amateur-radio operators in the world.

Waivers Waived

THE FCC HAS DENIED two requests for waivers of the rules covering volunteer examinations. **Jim Gustafson 5Z4JD** asked permission to conduct an exam session with one Advanced- and two Extra-class hams (the rules require three Extras). In denying the petition, the Commission said, "To establish such a precedent by waiving the requirement could easily lead to many similar requests, all of which would attempt to show a unique circumstance which would tend to make compliance with the three-VE requirement a hardship." (Ever notice how it takes the FCC a full paragraph to say, "No"?) **John Mulville KA0TNS** filed the other request. He asked for a waiver of the 13-wpm Morse test, citing a medical condition that would impair his ability to copy code. Said the Commission, "That requirement is so basic to the Amateur Service that waivers of it *are not granted*."

AL Together Now

COMPLAINING THAT, "Alabama has been made an island," repeater owners in that state have petitioned the **Carolina Virginia Repeater Association (CVRA)** for membership. Several months ago the Alabama Repeater Council directed all repeater owners to move immediately to a 20-kHz-spacing plan or lose their coordinated status ("QRX," June, 1985), even though surrounding states use a 15-kHz plan. Now the owners want to be coordinated on a regional rather than state basis, and are forming what will be the Alabama district of the CVRA. If the CVRA approves the petition, a thorough survey will be taken of all repeater operators in the state to determine whether or not a move back to 15-kHz spacing will be made. The CVRA coordinates repeaters in Georgia and Tennessee as well as the Carolinas and Virginia; Mississippi also is considering joining the organization.

Winner

INADVERTENTLY LEFT OUT of our 1985 75m World SSB Championship results was **Dr. Max de Henseler HB9RS**, president of the United Nations Amateur Radio Club. Max piloted **4U1UN** to a Class A Single-Op win with 520 QSO points and 22 multipliers for a total of 11,440 points. Max will receive a certificate for being the top scorer in his country (in fact, 4U1UN is the *only* station in that country. . .a guaranteed win!). By the way, if you contacted any two of the three UN "countries" last year, you are eligible for the **United Nations at 40 Award**. (The three calls are 4U1UN United Nations Headquarters, 4U1ITU Geneva, and 4U1VIC Vienna.) Drop a note to any of the three at its *Callbook* address.

The shack at 4U1UN.

DXCC + 1?

SPEAKING OF single-station countries, why not add the Council of European Headquarters in Strasbourg, France? Gus Browning, in his *DX'ers Magazine*, says that the station will have extraterritorial status, just like all of the United Nations buildings. Look for the prefix **TP21**—I'm sure the DXCC desk will be eager to add a "new one." Gus also mentions that VK3SX is looking for just a few more states to complete WAS on 40m: Arkansas, Delaware, Hawaii, Idaho, Nebraska, Nevada, New York(!), North Dakota, Oklahoma, Oregon, and West Virginia. Want to help him out? Drop a line to Bob Robinson VK3SX, 81 Bishop St., Yarraville 3013, Melbourne, Australia.

AM Appeal

THE US COURT OF APPEALS has upheld a decision by the FCC which sets the maximum amateur output power at 1500 Watts PEP. **Glenn Baxter K1MAN** fought the rule in court, claiming that it would adversely affect double-sideband operation by halving the maximum output (currently it is 3,000 Watts—the Commission has postponed the implementation of the 1500-Watt rule for DSB until 1990). Baxter can now appeal his case only to the US Supreme Court.

Opening

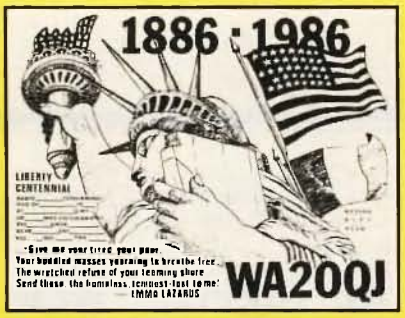
***73* MAGAZINE** has an opening on the editorial staff for a Technical Editor. If you are interested in living and working in the tax-free hills of New Hampshire, send your resume to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: Jack Burnett.

OSCAR Orbits

PROJECT OSCAR has prepared a complete set of orbital predictions for 1986. The tables list the time and longitude for all north-to-south equatorial crossings of RS-5, RS-7, and the two University of Surrey satellites (OSCAR 9 and OSCAR 11). Also, the time, sub-satellite latitude and longitude, and argument of perigee are given for the apogee of each orbit of AMSAT-OSCAR 10. Project OSCAR also has prepared *The AMSAT Phase III Satellite Operations Manual*, a 110-page book covering operating procedures and technical

details of the new series of OSCAR satellites. The orbital listings are available for a $10.00 donation and the manual for a $15.00 donation: Send your orders to Project OSCAR, Inc., PO Box 1136, Los Altos CA 94023.

QSL Liberty



THE FIRST ENTRANT I've seen in the Statue-of-Liberty-Centennial-QSL department is a really nice one from **Al La Vorgna WA2OQJ**. Al's card is 8" × 10", and you can get one by working WA2OQJ any time during 1986. Al says that he is RTTY-active on both 20m and 2m and also is on packet. Anyone else issuing a commemorative card this year? Let me know!

MetroSat

WHOEVER IT WAS that came up with the name "Amateur Radio" must be doing some double takes these days—our hobby is far from amateur! And just when you thought packet radio was the hottest item on the ham menu, along comes the **Metroplex Network**. The Network is a satellite-based news system designed expressly for amateur radio. Three programs, co-produced by Metroplex and Westlink Radio, are now being transmitted: a weekly news show, a weekly swap-and-shop service, and three North American Teleconference Radio Nets per year. Affiliated club stations can downlink the shows from a commercial satellite transponder for a fee, receive them via a UHF link, or connect to the network over the telephone. A new package is available every Monday night at 10:00 pm EST. Alex Magosci WB2MGB can give you more details about network affiliation—get in touch with him at the Metroplex Network, PO Box 237, Leonia NJ 07605, or call (201)-592-7614 for a taped message.

On The Table

YOUR CHANCE to get a real picture of Comet Halley taken from a real observatory by a real astronomer is coming up this month. **Jim Young WB6FNI**, resident astronomer at the Jet Propulsion Laboratory's Table Mountain Observatory, will commemorate the celebrated slushball by operating from Table Mountain during February and March, 1986. Jim says that this will be a forty-meter-only affair and will be done on a noninterference basis with normal observatory activities. Frequencies (in MHz), modes, and times (in UTC) are: 7.120 CW 0400-0500, 7.228/7.077 SSB (split for DX to Europe and Africa) 0500-0600, 7.249 SSB 0600-0700, 7.249 SSB (on the Triple-H Net) 0700-0800, 7.228 SSB (looking for South Pacific, Australian, and New Zealand stations) 0800-0900, and 7.228/7.084 SSB (split for DX to Asia and the Far East) 0900-1000. Jim will answer your QSL with a certificate and an original Halley's Comet photo taken from the Table Mountain Observatory. Send your card and a #10 SASE (with 40¢ postage) or 5 IRCs to Jim Young WB6FNI, PO Box 576, Wrightwood CA 92397.

Al WA2OQJ's commemorative QSL.

Pollish Hams

OUR 6TH ANNUAL "Fun!" poll is here! Conducted by columnist **John Edwards KI2U**, this year's survey probes the collective psyche of ham radio with questions such as, "Should hams be subject to periodic retesting?" and, "Do you think nets have a place in ham radio?" This is your chance to directly effect changes in *73*—we take the results of this poll very seriously and use them to determine just what it is that our readers want to see in the magazine. This year, you can send your answers to John electronically through CompuServe (70007,412) or The Source (CPA117). See you at the polls!

Write On!

HAVE YOU EVER read an article in *73* and said to yourself, "Gee, I could do that!"? You're right—you could. In fact, we're *asking* you to write an article for us! And, as a special bonus for "QRX" readers, I'll give you a few inside tips that will help sell your manuscript. First, pick a topic that hasn't been beaten to death already. For example, a logging program for your computer probably will not make the grade. Statistically, the most-accepted topics are antenna construction and modifications. Second, include plenty of photographs—a good picture can sometimes sell an otherwise dull article. Include captions for your shots on a separate sheet, and lightly, with a pencil, mark the back of each print with a letter or number. Third, be yourself. Just write down your ideas as you would say them to someone standing in the room with you—long words and complicated phrases just make a manuscript hard to understand. Finally, if you can't come up with an article, try writing a review. It doesn't have to be a component-by-component engineering analysis, just a summary of what you liked and disliked about the product. Again, take plenty of pictures. If you want a step-by-step guide to becoming a *73* author, send an SASE to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: How to Write.

Think Thinkers

THE COMPUTER MUSEUM in downtown Boston, in conjunction with Computer-Land and CW Communications, is searching for relics left over from the early days of computing. They are looking for just about anything that smells of mold: kits, cards, one-of-a-kinds, and memorabilia. If your item is selected to become part of the exhibit on computer evolution, you'll receive an invitation to the grand opening and a bound copy of the exhibit catalog. If yours is one of the "fantastic five" pieces, as determined by a distinguished panel of experts, the Museum will pay your way down to Beantown (and home again) for the big opening bash. Get in touch with the Museum for an official entry form, or just mail a picture and a description of your entry to The Computer Museum, Personal Computer Competition, 300 Congress Street, Museum Wharf, Boston MA 02110; (617)-426-2800.

Packet Paper

GWYN REEDY N1BEL dropped by the office recently to tell us about a new magazine for packet-radio enthusiasts, called (appropriately) ***Packet Radio Magazine***. The magazine is an extension of the Florida Amateur Digital Communications Association's *FADCA>Beacon* (a *73* Newsletter of the Month winner) and will be distributed nationwide. Space will be made available in each issue for local clubs to use; Gwyn says that this arrangement will let local groups use *Packet Radio* as their club "newsletter" and will also keep packet organizations around the US up-to-date on each other's progress. If you or your club is interested in *Packet Radio Magazine*, get in touch with Gwyn at FADCA, Inc., 812 Childers Loop, Brandon FL 33511.

Friends

"QRX" was brought to you this month with the help of the *W5YI Report, Amateur Satellite Report,* the *FADCA>Beacon,* Gus Browning's *DX'ers Magazine,* and *Westlink*. Don't forget to send your news items and photographs to *73* Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458.

Garden Grove CA 92641

Razor-Sharp CW

Here's a filter for fanatics—or is 80 Hz too wide?

The Kenwood TS-430S is without doubt one of the best of the smaller mobile-size HF transceivers on the market today. With its many modes and logical memory-control operation, it is truly excellent for mobile operation. *All* of my operation is mobile . . . and CW is my preferred mode. My work as a traveling salesman requires me to spend many hours behind the wheel of my car each week, and my mobile CW operations make those hours fun instead of boring!

With my primary interest being CW, I saw only one small deficiency in the operation of the TS-430S on CW: Kenwood did not make any provision for installation of an active audio filter for improved reception. I tried their 270-Hz i-f filter, and although it is nice as i-f filters go, it is no substitute for a good narrow active audio filter. (Having both is ideal!)

I have been building and using active audio filters for CW receivers for years and have long since recognized their performance advantages. I made the decision to modify my TS-430S even before I purchased the rig.

Squeezing In a Filter

When I unpacked my brand-new rig, I gave it only a quick check to ensure that its "stock" operation was without problems before I removed the cabinet covers and started searching for an area within the rig that would have the spare room to install a good CW filter. I found several good possibilities and, for my unit, decided on the area directly under the top cover and to the left, just in front of the filter unit (X51-1290-00—see instruction manual, page 27).

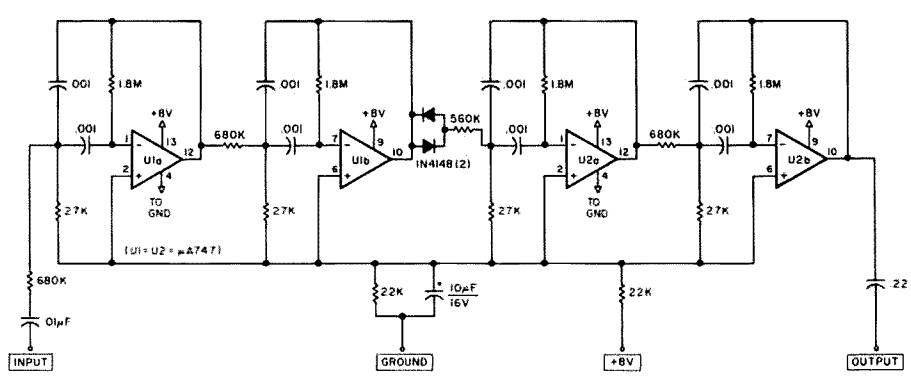
This is a fine location as long as you keep the CW filter board low profile (lay resistors and "long" components down on the board; don't stand them on end). Another good possible location would be the space allocated for the optional FM-430 (FM mode unit)—if you do not have the FM unit installed and do not plan to do so.

Circuit Details

The schematic diagram of the CW filter I developed for the TS-430S is shown in Fig. 1. The circuit consists of four stages of active bandpass filtering provided by two type-uA747 integrated-circuit dual op amps and includes a simple threshold detector (diodes D1 and D2) between stages 2 and 3 to reduce low-level background noise. Each of the four filter stages acts as a narrow bandpass filter with an audio bandpass centered at 750 Hz.

The four stages together result in an excellent and extremely narrow CW filter that will pass a 750-Hz CW note with no attenuation but will reject adjacent signals so well that an audio note below 600 or above 900 Hz can barely be heard. The actual measured 3-dB bandwidth is only 80 Hz wide . . . truly a "razor sharp" CW filter!

I strongly suggest using polycarbonate or other temperature-stable capacitors for each of the eight .001-uF capacitors, with a capacitance tolerance of ±5% or less, to ensure that each of the four stages of filtering will be correctly tuned to identical bandpass frequencies. If you are a real calibration fanatic, you can tweak the bandpass frequencies of each stage by adjusting the value of its 27k resistor. (In-



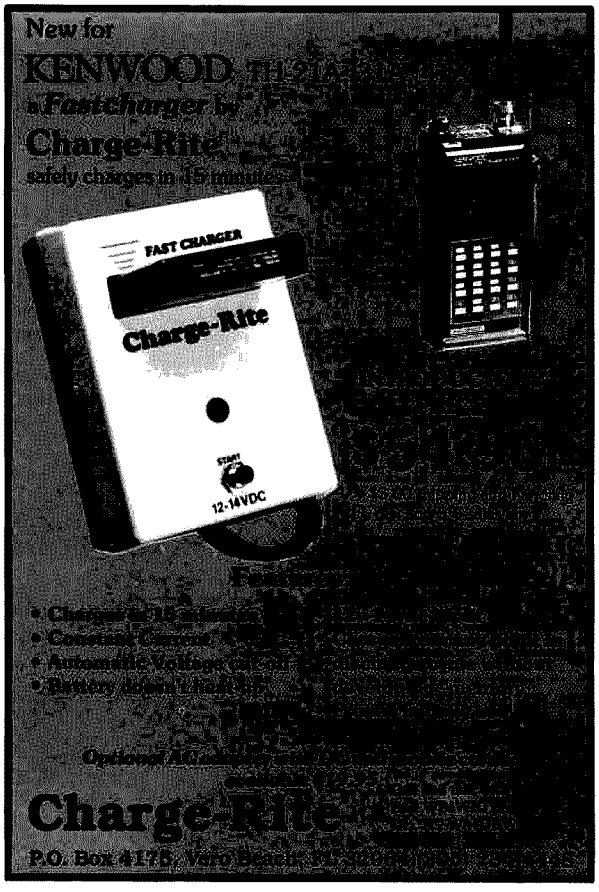


Fig. 1. Schematic diagram.

creasing the resistance will lower the bandpass frequency.) In actual practice, you will probably find that the four stages don't really have to be *perfect*. . . just close enough so that all four stages will pass the desired audio frequency of 750 Hz.

I constructed my filter on a small piece of perfboard, with components on one side of the board and small-gauge insulated wires forming all interconnections on the reverse side.

Initial Checkout

After completing the circuit construction, it would be a good idea to verify the circuit's operation before installation in your TS-430S. Using a 9-volt battery for power, connect the filter input to the rig's headphone output and listen to the filter output with high-impedance headphones, tuning across a carrier or CW signal to ensure that the filter passes a clean sounding signal at about 750 Hz but rejects it when you tune higher or lower. If all has gone well so far, you are undoubtedly very impressed with this filter and your handicraft by now, and you *may* elect to stop right there and use the filter board with the nine-volt battery. Feel free to quit here and build the filter into a small box to use as is with any rig and headphones, if you like.

Installation

Like me, you will probably prefer to build this filter right into the TS-430S since this saves having to carry an extra box with you and allows the great convenience of a feature which can be switched in and out as needed and will drive the TS-430S speaker as well as headphones.

The installation I will describe is simple and will end up with the filter operating as if Kenwood had designed it in yet will allow you to easily "un-modify" the rig at any time in the future if you want to sell it "stock" and keep your super little filter to install in a *new* rig.

The filter, as I installed it, will modify the operation of the front-panel ALC/IC meter switch so that it becomes your new audio filter in/out switch. I elected to use this switch (leaving the transmit meter permanently in the IC mode) because I never use the ALC position anyway. This is a very small price to pay to have the CW filter switch in the ideal position!

You may prefer to use something else, such as the noise blanker switch, or whatever, but using an existing switch means you won't have to drill any holes in that beautiful front panel to mount a new one.

For the actual circuit-board mounting, I took the easy way out. Rather than drilling holes, I just enclosed the circuit in a small plastic bag with the four interconnecting leads coming out one corner and let the whole assembly float in the left-rear corner of the rig. It is confined in its location by nearby components yet can't possibly short to anything through the plastic.

Here is the installation procedure for the TS-430S in 5 easy steps:

(1) Unplug connector 4 on the i-f board. Connect Ground from the filter board to pin 2 on connector 4. Remove pin 4 from connector 4 and connect *board pin* 4 to a long insulated wire *and* to Input on the filter circuit.

(2) Unplug connector 14 on the i-f board and connect:
- —connector 14 pin 1 to the long insulated wire you connected in step 1
- —connector 14 pin 2 to connector 4 pin 4
- —connector 14 pin 3 to Output of filter circuit

(3) Connect +8 volts from the filter circuit to pin 3 of connector 7 on the i-f board.

(4) Disconnect blue wire from the (+) side of the S-meter, tape over the wire end so it will not short to anything, and tuck into nearby wiring.

(5) Connect an insulated wire from the S-meter (+) connector to i-f board connector 14, board pins 2 and 3. This completes the installation.

Note: In the TS-430S instruction manual, i-f board connector 14, *in the i-f board schematic*, IC is shown incorrectly as being on pin 1. It should be pin 3—as is correctly shown on the *main schematic* in the manual.

Operation

If you are not now used to operating CW with a filter such as this one, you may find that you will need to change your operating style just a bit. This filter is so narrow that if you tune rapidly across the band with the filter switched in, you will completely miss some signals.

In my normal operating practice, I tune through the band with the filter switched out, then switch it in when I want to really focus in on a particular CW signal. Once that signal is in your filter, you can hit the frequency-lock button on your TS-430S and you really are locked on that station. As long as he does not have a frequency drift on his signal, you will not have to touch your rig again, and you will most likely never hear any other stations during your entire QSO unless you elect to switch the filter out to see what is happening around your frequency.

This modification has certainly increased my enjoyment of CW operating, and I'm sure you will find that having a filter like this in your TS-430S will encourage you to operate a lot more CW. If you also install the optional Kenwood narrow i-f filter (270 Hz), the winning combination will offer CW selectivity second to none! ■

New Bands for Old Rigs

Internal or external, converter or transverter, here's how to add three WARC bands to your favorite radio.

Charles Bryant GW3SB/G3SB
2 Penrhyn, Saint Michael's Road
Minehead, Somerset TA24 5JP
England

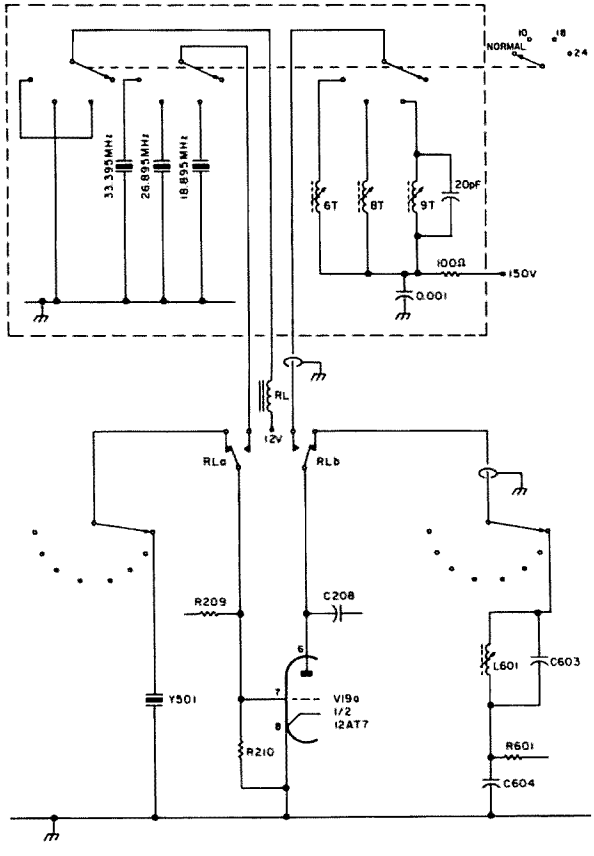

Fig. 1. Modified hfo circuit of the HW-101. Third-overtone crystals are used, inductances wound on 7mm formers with turns spaced the diameter of the wire.

With the 10-MHz band in worldwide use and more countries coming on 18 and 24 MHz each week, now is the time to think seriously about getting started on the WARC bands—if you haven't already done so!

The easiest way is to buy a new rig, and many amateurs are doing just this, with the result that there are some very good five-band rigs on the market at reasonable prices. However, it is not too difficult to find a way of modifying an existing five-band rig to cover eight bands. There are at least three methods of doing so, and this article reviews the advantages—and the snags.

Internal Modification

The most elegant method is to make an internal modification, but this is usually quite difficult. If your rig is a transceiver with provision for the reception of WWV on 10 MHz, it is not too hard to change the connections to allow transmission also. Many owners of popular rigs, such as the FT-101 series, have done so. However, some rigs provide for reception of WWV on another frequency, and these rigs are not so easily changed.

It may be thought that with the low sunspot count, the whole of the 28-MHz band is not required and some of these circuits can be changed. This looks attractive *provided* that the switching arrangements allow. I have found that most rigs use a single set of inductors in some circuits for the whole of the 28-MHz band. The alterations would therefore be extremely complicated, and a different approach would be much easier.

Although I have not tried it myself, the modification of the Heath HW-8 should be fairly simple. Because band changing is accom-

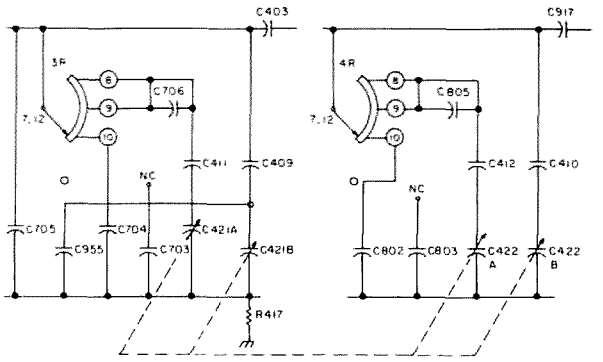

Fig. 2(a). Tuned circuits (inductors omitted) of driver input and output before modification.

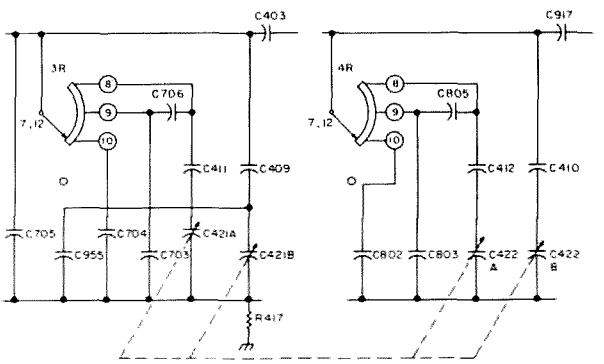
plished by push-button on/off switches combined with diodes, all circuits can be isolated effectively when all the bandswitches are in the off position. Three more complete circuits can be constructed and mounted on a board fixed about ½" below the existing PCB. Each separate circuit should be positioned as close as possible beneath the corresponding one on the PCB. It may be necessary to make the cabinet a little deeper and, of course, it will be necessary to add three new switches with their associated diodes. Incidentally, the same arrangement could be used to add the 1.8-MHz band to this popular QRP rig.

Converter—Transverter

If you use a separate receiver (or are prepared to use your existing transceiver in the receive mode only) the use of a converter in front of the rig is the obvious method. Circuits for converters are common. LA8AK (in *Radio Communication*, May, 1983, page 427) and DL1ZB (in *SPRAT*, Summer, 1983, pages 9-11) have suggested that by using a single 4-MHz crystal, the 10- and 18-MHz bands are covered with the main receiver tuned to 14 MHz, and the 24-MHz band can be found with the receiver tuned to 28 MHz.

At least for the CW operator, it may prove easier to build a simple CW transmitter for use with the main rig, plus a converter.

There is no reason why a transverter should not be used. For QRP operators this course is possible and circuits have been published. As transverters are really practicable only at low power, this method is likely to appeal only to the QRP fraternity (the circuits I have seen have all been designed for a power of 10 W or under).



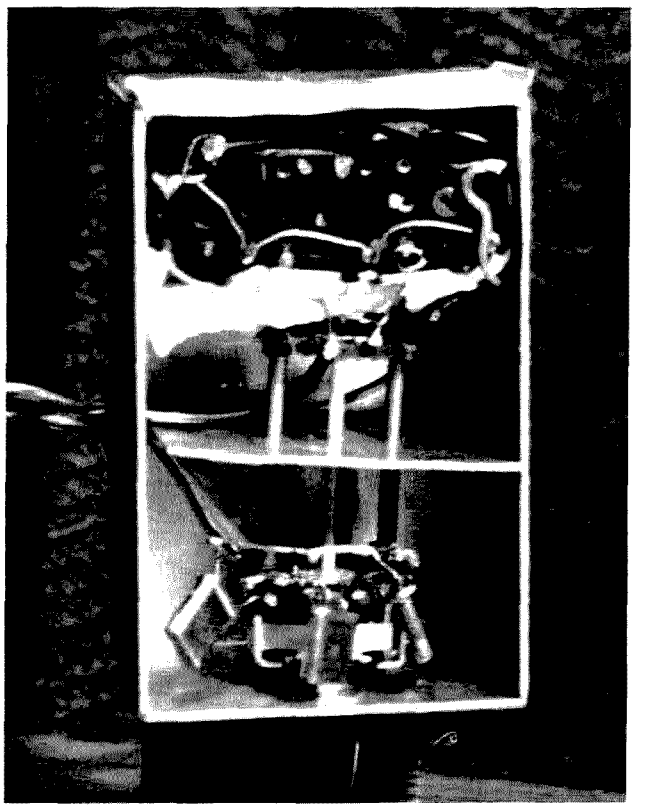


Fig. 2(b). Tuned circuits (inductors omitted) of driver input and output after modification to enable 7 and 10 MHz to be tuned with one inductor.

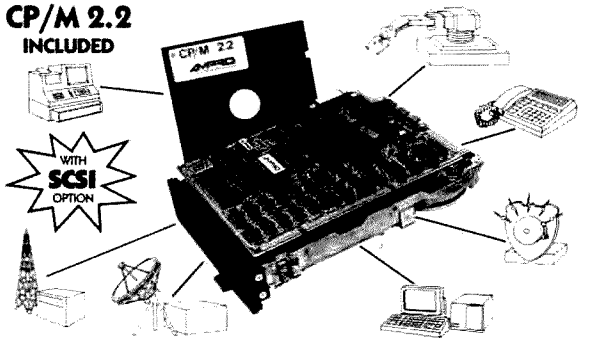
The new hfo circuits and switch are in the small box to the right of the HW-101.

External modification

This is the method I have used and which will, in most instances, prove to be the easiest approach. The modification consists of breaking the connections from the crystal and tuned-circuit switches of the hfo and inserting a small changeover relay to allow either the existing circuits or new ones, contained in a small external screened box, to be connected to the oscillator. If the rig has a source of 12 V dc, there is no difficulty in providing excitation for this



Inside the box containing the new hfo circuits and switch.

Little Board™ $249

The World's Least Expensive CP/M Engine

CP/M 2.2 INCLUDED

- 4 MHz Z80A CPU, 64K RAM, Z80A CTC, 4-32K EPROM
- Mini/Micro Floppy Controller (1-4 Drives, Single/Double Density, 1-2 sided 40/80 track)
- 2 RS232C Serial Ports (75-9600 baud & 75-38, 400 baud), 1 Centronics Printer Port
- Power Requirement: +5VDC at .75A, +12VDC at .05A / On board -12V converter
- Only 5.75 x 7.75 inches, mounts directly to a 5-1/4" disk drive
- Comprehensive Software Included:
  - Enhanced CP/M 2.2 operating system with ZCPR3
- Read/write/format dozens of floppy formats (IBM PC-DOS, KAYPRO, OSBORNE, MORROW...)

relay. In the case of older rigs, a couple of diodes and a 100-uF capacitor can be connected to the 12-V heater line to provide the necessary dc. It does not matter whether the positive or negative line is connected to ground.

In *Radio Communication* for April, 1982, on page 317, I described my modification of the Heath HW-101 to include the three new bands. This is an expanded version of my original proposals. One advantage of this modification is that it does not involve any mutilation of the equipment, which can, if necessary, be restored to its original form.

The new bandswitch, with associated components, is assembled in a small screened box with an internal screen between the wafers. The size of this box depends on the size of the switch. I used wire-ended crystals which were soldered directly onto the switch, but sockets and plug-in crystals could be used if desired. The components in the other compartment are all supported by their wiring. The simplicity of the circuit is shown in Fig. 1, where component values are placed against *new* components and the existing components are shown with the reference numbers given by Heath.

The leads from the screened box to the rig should be as short as possible. The lead to the tuned circuit must be of miniature coax, but the lead in the crystal circuit and the relay lead may both be unscreened. Originally, I used coax for the crystal lead, but the additional capacitance caused difficulties. To avoid drilling the cabinet of the HW-101, the leads may be fed through the ventilation holes in the bottom of the cabinet. In operation, the box is placed alongside the HW-101.

The relay is positioned as near to the underside of the socket of V19 as possible. The existing black lead passing through hole Z on the "bandpass circuit board" should be unsoldered and rerouted through hole TP so that it may be connected to the relay. All the connections to the relay are thus quite short, and there should be no appreciable change to the operating conditions on the old bands. However, some realignment is necessary before the new bands can be tuned.

By juggling with the slugs in both sets of driver coils (L705, L704, L703, L702, L805, L804, L803, and L802), it is possible to tune to 24 MHz with the "driver preselector" near maximum capacitance and 28 MHz with the capacitor near minimum. Similarly, 18 and 21 MHz can be covered together without any difficulty. A problem arises on 7 and 10 MHz because the capacitance swing is insufficient to cover both bands. The solution to this problem lies in disconnecting C703 from contact 9 of wafer 3R on the "driver grid switchboard" and joining contact 9 to contact 8. Similarly, C803 should be disconnected from contact 9 of wafer 4R on the "driver plate switchboard," and contact 9 should be joined to contact 8. Although this sounds very difficult, a glance at Figs. 2(a) and 2(b) will explain what is involved.

These modifications allow 7 MHz to be tuned near maximum capacitance and 10.1 MHz near minimum capacitance. However, a word of warning: *8.6 MHz also tunes at an intermediate position*. It is essential to make sure that the tuning is correct before transmitting, and a simple test is available. If changing the switch from "normal" to "10 MHz" does *not* affect the signal being received, then the "driver preselector" is wrongly tuned to 8.6 MHz.

I have had no difficulty since making the original modification in 1981, and the performance on the old bands (except the high part of 28 MHz) has not been affected. I should, however, point out that I work exclusively on CW; there may be difficulties on SSB if the output circuit is not optimum. There is also the additional point that the tuning of 24 MHz and 28 MHz in one circuit will result in a considerable reduction of drive on the higher parts of the 28-MHz band.

I have described this modification in some detail, and owners of HW-101s should have no difficulty in duplicating my modification. Owners of other equipment may well feel encouraged to attempt a similar approach.

Antennas

Having got your rig on the new bands, there is no need to erect a new antenna in order to try it out. Use your existing 3.5-MHz dipole (trap dipoles are not recommended) or G5RV antenna. This may not be the perfect answer, but it will get you out on the bands. ■

Parts List

1—Aluminum box, 10 x 5 x 5 cm with lid and internal screen
1—3-bank, 4-position rotary switch with knob
1—18.895-MHz third-overtone crystal
1—26.895-MHz third-overtone crystal
1—33.395-MHz third-overtone crystal
3—7mm coil formers with iron cores
1—0.001-uF capacitor
1—20-pF capacitor
1—100-Ohm resistor
1—12-V operating miniature double-pole changeover relay
Miniature coax and other connecting wire

Razzle-Dazzlin' Your Azden

Some sleight-of-hand with a fistful of parts will make your PCS-2000 a 2m star!

Are you tired of replacing the silver-oxide memory backup cells in your Azden? Have you discovered the hard way that the PCS-2000 draws nearly 20 milliamps from your automobile battery when the power switch is off? Do you sometimes find yourself wishing there was an easy way to quickly sample the repeater input frequency when receiving? How about some hang time when in the scan mode; wouldn't it be nice if the receiver would pause for a few seconds after the repeater dropped off, to allow for that slow-to-respond fellow? This article deals with all these problems and more, with some easy and reliable modifications.

Disassembling the Control Head

All the changes described in this article are made within the control head itself; no changes are made to the main radio chassis.

Separate the control head from the main chassis. Remove the top and bottom plates; there is a single screw on each side of each panel. (Page 17 of the Azden instruction manual shows this procedure.) Now remove the four screws on the back plate; also remove the single chrome-plated screw in the right rear corner of the control board. This will allow the rear plate to dangle on the speaker-jack leads. This jack must be removed to allow room for the addition of the battery pack as described in a later paragraph. Unscrew the speaker jack from the rear plate; set the three cover plates and all the screws aside.

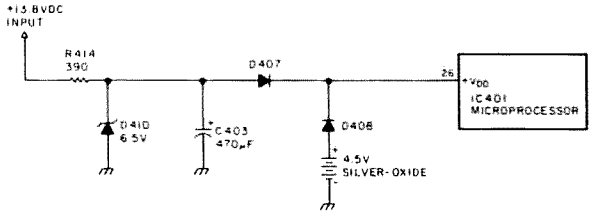

Fig. 1. Original memory-protection circuit uses three silver-oxide cells and charge-protection diode D408 to apply power to the microprocessor while the main power is off.

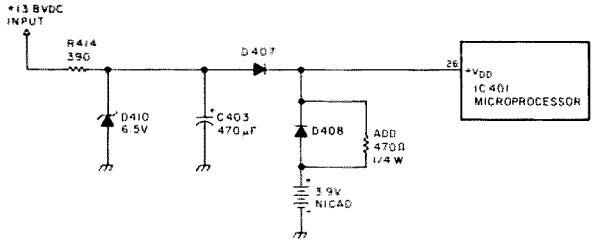

Fig. 2. Modified memory-protection circuit uses a three-cell nicad pack instead of the silver-oxide cells. Adding a 470-Ohm resistor across D408 allows the nicad pack to charge whenever the radio is operated.

Adding a Nicad Battery Pack

The first change we can make is to replace those expensive little silver-oxide cells with a nickel-cadmium battery pack which is recharged every time the transceiver is used. The original circuit (Fig. 1) has diode protection (D408) for a depleted or shorted cell, but this same diode also blocks any charging current to the memory battery (we wouldn't want to try to charge the silver-oxide cells). As shown in Fig. 2, the simple addition of a resistor across D408 will allow charging current to flow into the battery when the power switch is on.

The battery pack should be a three- or four-cell pack, readily available, and small enough to fit into the confines of the Azden control head. The available space is large enough to hold a cylindrical battery approximately 3/4 of an inch in diameter and up to 2-1/8 inches long. I chose a common pager battery made of three cells (nominally rated at 3.9 volts, 140 mA hours). The battery is Motorola part number 60D83009H02 and can be obtained at any authorized Motorola Service Center (they are numerous); they should also be available from any service shop that repairs pocket pagers. Since a very large number of these batteries is manufactured each year, the price is quite reasonable; they sell for less than ten dollars each. This is just slightly more than the price of one set of consumable silver-oxide cells.

After obtaining the battery pack, a set of leads must be attached. *Do not* try to solder the leads directly to the battery. Unfortunately, this battery is not equipped with solder tabs, but with a little effort and thought, a reliable connection can be made. One way of attaching leads is to solder a small

solder lug to the end of each of the two leads and then tape the lugs in place against the ends of the battery, forming a homemade battery holder. (I placed small pieces of foam rubber on top of the lugs and underneath the tape as a sort of spring to ensure a good, firm connection at all times.) The lugs should be plated rather than bare copper. This will ensure trouble-free contacts in the future. Wrap the whole assembly in tape or kraft paper to guard against short circuits; remember this pack must squeeze into a small space in close proximity to the foil side of a printed circuit board.

We must next modify the circuit of Fig. 1 to allow the battery to be charged. Locate D408; it is on the main control board just to the left of the old battery holder. Solder a 470-Ohm, ¼-Watt resistor across this diode. This should be done on the component side of the board if you plan to implement the other modifications in this article. If the leads are pre-tinned, it is quite easy to tack the resistor right onto the leads of the diode.

Finally, the battery pack must be soldered into the circuit. (If you plan to make more modifications, it will be easier if the battery is not yet attached to the control head.) Before the battery is installed in the head, it is a good idea to charge it; most nicad batteries are at least partially discharged when purchased due to their relatively short shelf life. Charge the battery by applying 12 to 14 volts through a 1000-Ohm, ¼-Watt resistor for at least ten hours. Now pre-tin the leads and the two clips on the old battery holder. Try to attach the wires slightly down the sides of the clips because there is very little clearance between the clips and the top plate when it is restored. The battery leads can be soldered to the back side of the board, but this area is best reserved for some of the following modifications. The battery fits vertically in the space directly behind the scan-mode switch.

Battery Capacity and Life

The 470-Ohm resistor in combination with the nominal 4-volt battery causes about 3.6 milliamps of charge current whenever the power switch is turned on. The memory-backup drain with the power switch off measured about 75 microamps on my radio. If we assume an average typical operating time of one hour per day (to and from work, for example), then the battery will be charged for one hour and discharged for 23 hours out of each day.

A typical nicad battery is only about sixty percent efficient when charging, so the total charge per day will be $3600 \times 0.6 \times 1 = 2160$, or about 2 milliamp/hours per day. The battery will discharge for 23 hours at about 75 microamps, thus the discharge will be $75 \times 23 = 1725$ or about 1.8 milliamp/hours per day. Thus our battery should stay charged if the radio is used an average of 45 minutes for every 24 hours that it is off. These are worst-case figures, and in reality the battery probably needs only about 30 minutes of charge per day. Also note that as the battery becomes discharged, the charge rate will increase slightly due to the increased battery terminal voltage.

With a discharge rate of 75 microamps and a battery rating of 140 mAh, we can predict how long the battery pack will protect the memory without ever being recharged (if, for example, the radio goes unused for several days). Most cylindrical nicad packs exhibit an increase in their Ampere/hour capacity when discharged at a very low rate (we qualify). This increase is in the order of thirty percent. Thus, $140{,}000 \times 1.3 = 182{,}000$ effective μAh. Dividing this by 75 microamps and 24 hours, we can predict that this battery should keep the memory happy for more than three months.

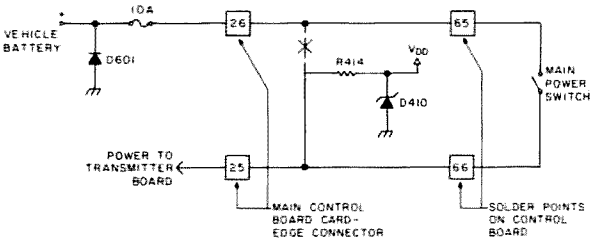

Fig. 3. Moving R414 to the cold side of the power switch eliminates current drain from the vehicle battery when powered off.

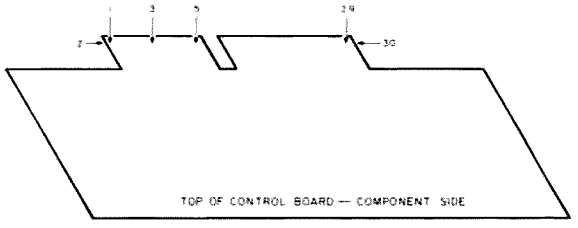

Fig. 4. Numbering sequence for control-board card-edge connector. Odd numbers are on top; even numbers are on the solder side.

The charge rate of 3.6 milliamps was chosen to be what is known as a minimum rate. This rate of charge is safe for continuous charging without harming the battery. If you wish to modify the charge rate, all that is necessary is to change the added resistor to a new value found by subtracting the battery float voltage from 5.9 volts and dividing the answer by the desired current. The 5.9 volts is the regulated Vdd found on the control board which we use to charge the battery. Be careful not to load this too heavily. A little experimenting will show quickly what is too much.

Reducing the Standby Current Drain

My Azden PCS-2000 came from the factory wired in such a way that it consumed 20 milliamperes from the primary power source even when the main power switch was off. The industry-accepted standard for mobile radios dictates a primary power connection directly to the vehicle battery. Under worst-case conditions—very cold weather, for example—it is possible that after an extended period of non-use this constant discharge could prevent a vehicle from starting. To eliminate this possibility, rewire the control processor board power as shown in Fig. 3.

This change is made very simply by moving one end of resistor R414 from main card-edge connector pin 26 to pin 25. Fig. 4 shows the proper numbering sequence of this connector. Trace pin 26 along the foil until you find R414. Lift this end of R414 from the board and tack it back down on a solder pad—about a quarter inch away—which comes from connector pin 25.

The result of this change is that standby current drain when the main power switch is off drops to an insignificant few tens of nanoamperes. This current comes from the reverse leakage in the power transistors in the rf PA module.

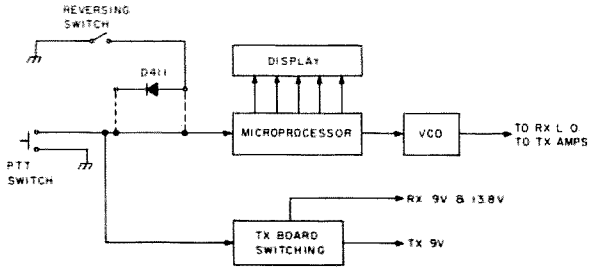

Fig. 5. Engaging the PTT switch causes the microprocessor to change the vco to the transmit frequency and causes the transmit switching to mute the receiver and turn on the transmitter. Adding diode D411 and the reversing switch allows the processor to be switched to the transmit frequency while staying in the receive mode.

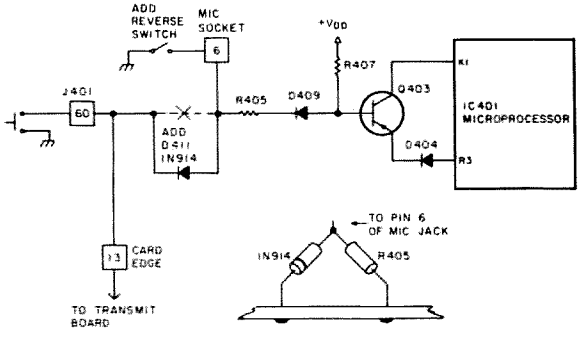

Fig. 6. Reversing switch is mounted in the microphone case. Lift one end of R405 and add D411 as shown.

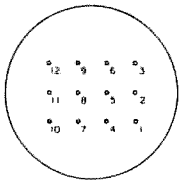

Fig. 7. Front view of the microphone jack showing the pin-numbering sequence.

Add a Reverse-Input Switch

Because of the way the microprocessor functions, it is very simple to fool the receiver into listening on the repeater's input instead of the output. Refer to Fig. 5. One of the things that happens when the microphone PTT switch is pressed is that the microprocessor reprograms the vco for transmitting on the offset frequency. This PTT signal also goes to the transmitter board to enable the transmitter and disable the receiver. The processor also changes the display to show the offset frequency. By telling the processor that we wish to transmit but at the same time witholding this information from the transmitter, the radio will receive on the transmit frequency!

With the addition of a single diode (shown in Fig. 6) and a slide switch in the microphone case, we have an instant reversing switch. I mounted my switch in the space vacated by the remote squelch control. The loss of this external squelch pot was not a problem since it was never used anyway.

Separate the microphone case by removing the four screws in the back piece. Remove the squelch knob and potentiometer from the microphone case. (For those of you who have purchased the old-style Azden DTMF tone microphone option, the knob will be missing already.) There are two red wires and one slate (gray) wire attached to the squelch pot. The reds are common (ground) and will be attached to one side of the new slide switch; the slate wire goes to the other side of the switch. The physical mounting of the switch is made simple by the use of quick-setting epoxy glue. Larger switches make necessary the removal of the mounting posts that held the squelch pot. Choose a switch whose slide arm doesn't stick through the case too far and whose action is stiff enough to preclude accidental operation when handling the microphone. Reassemble the microphone, being careful not to pinch any of the tiny wires.

At the control head, locate R405 (all the parts on this board are well labeled with white silkscreening). Find the end that connects to the cathode of D409. Unsolder *the other end* of R405 and lift it off the board. Insert the cathode end of a new diode, a 1N914, into the board where R405 was. Twist together the anode end of the new diode and the free end of R405. Connect to this junction a four-inch piece of insulated wire. Turn the control head onto its face and find the board holding all the potentiometers and switches.

Locate a large electrolytic and a 22-Ohm resistor. On the solder side of the board, about ¼ of an inch below the 22-Ohm resistor (towards the LEDs), there should be a pink wire coming from pin 6 of the microphone socket. Lift the board end of this wire and connect it to the four-inch length of wire coming from the new diode. Insulate the splice. See Fig. 7 for pin numbers of the microphone socket.

Refer to Fig. 6 for the following explanation. When the reverse switch is thrown, a ground is placed through the switch to the junction of the new diode (D411) and R405. This ground is reflected through R405 and D409 to the base of Q403 causing it to conduct, tying processor lines R3 and K1 together. This is the signal to the processor to change to the offset frequency. At the same time, the ground from the microphone is blocked by D411 from getting to the transmitter board. Thus the radio remains in the receive mode, but on the transmit (offset) frequency.

Note that this is a receiver-reversing, not a transmitter-reversing switch; if the PTT switch is pressed while in the reverse mode, the transmitter will come up at whichever frequency is stored as the offset. Saying it another way, the transmit frequency is not affected by either position of this new switch. Also note that the reversing switch relies upon the stored offset to function; if the radio is in the simplex mode, throwing the reverse switch will do absolutely nothing.

Scan Hang Time and Scan Sample Mode

The idea of scan hang time—the pausing of the scan for a few seconds before continuing after a channel becomes clear—is certainly not new. But it is indeed a most welcomed asset; without it, any pause in the carrier on a scanned channel will result in the loss of that channel until the scan comes around again. While driving through a marginal area, every time the receiver squelches due to flutter or "picket-fencing," the scan will resume and the channel will be momentarily lost. The addition of a few seconds of hang time will correct this aggravating situation.

Another mode of scanning is the sample mode. In this mode, scanning proceeds normally until an active channel is found; however, instead of staying locked to that channel until

it is cleared, the sample mode automatically forces a resume-scan trigger signal every few seconds. This allows a sampling of all active channels so that no one channel can lock out any other.

Under crowded band conditions this mode can become very confusing, but under the right conditions it can be very useful, giving a sort of priority channel function, ensuring that a certain channel will always be listened to at least once every few seconds. It seems that most hams have a favorite two or three repeaters they generally listen to, and if a "priority" repeater is programmed into every other memory location, then the listening duty cycle for that machine is very high and guaranteed by using the sample scan mode.

These last two additions are grouped together because the circuitry needed to implement them is centered around a single integrated circuit. Fig. 8 shows the circuitry involved with scanning. The important parts here are R406 and Q404. It is important to know that any time the SQ' line (control-board point 75) is pulled low, Q404 will conduct and scanning will stop. To resume scanning, all that is necessary is that the SQ' line be released to float high.

To begin a scan, something else happens, but once a scan is in progress, pulling line SQ' low will stop the scan and letting it go high will immediately start the scan again. This will continue until the scan is permanently stopped by pressing one of the stop keys or by keying the PTT button.

Another important bit of information we need to know is what happens to the line SQ SIG (control-board PC edge-connector pin 14) when a channel becomes active and inactive. This signal comes from the receiver board squelch circuits and goes high (positive) when a channel becomes active. Typical values are 7.5 volts high, 0.1 volts low.

Referring to Fig. 8, we will first examine the unmodified circuit. In the V or vacant mode, the receiver scans until it finds a vacant channel. A vacant channel will pull the SQ SIG low; this will be inverted to a high by Q401 and back to a low by Q402. This low will exit the control board via point 73, pass through the scan switch to the SQ' line, and stop the scan. In the B or busy mode, the receiver scans until it finds a busy channel. A busy channel will cause the SQ SIG line to go high. This is inverted to a low by Q401 and exits the board on point 74, passes through the scan switch to the SQ' line, and stops the scan. In either of these modes, as soon as the channel activity changes (for example, from active to squelched), the SQ SIG line toggles and the scan immediately resumes. In the F or free-scan mode, the scan switch simply opens the SQ' line and the receiver scans freely without ever stopping, regardless of channel activity.

It can now be seen that all that is needed to add some hang time to the B or busy mode is simply to add some delay to the SQ' line after the channel has squelched. If we add this delay in the form of an OR gate to the existing circuit, then the scan will be stopped by an active channel and held by the tail-end delay. The sample mode is much the same except that we remove the SQ SIG squelch input to the OR gate so that the only thing that stops the scan is a timer pulse triggered by the channel activity; when the timer runs out, the scan resumes.

Fig. 9 shows the added parts and how they interface with the existing circuitry. The V or vacant mode works the same as it always has. In the B or busy mode, diodes D412 and D413 make up an OR gate feeding the SQ' line through the scan switch. When a channel becomes busy, the SQ SIG line goes high and is inverted to a low by Q401. This low is fed through D412 to the SQ' line stopping the scan. As long as the channel is active, the scan will be stopped.

Now look at IC403-A and B; these gates, together with C411 and R418, form a pulse generator. The output pulse is a low-going pulse of about 2.5 seconds duration and is triggered by a low-going pulse at IC403 pin 2. While the channel is active, the high on SQ SIG is double-inverted by Q401 and Q402 and blocked by diode D414. When the channel clears, a

We Give You VHF Without VHC.*

(* - Very High Cost)

Presenting Microwave Modules, the low-cost way to full-featured multimode operation on 50 Mhz, 144 Mhz and 432 Mhz.

Expand your HF transceiver's capabilities for less than the cost of a VHF multimode radio.

All models feature:
- 25 Watts RF output
- Low Noise GaAsFET front end
- Transmit ALC circuit
- RF sensed VOX TR switching
- All-mode operation—SSB, CW, FM, AM
- Easy hook-up to your present HF transceiver

MICROWAVE MODULES

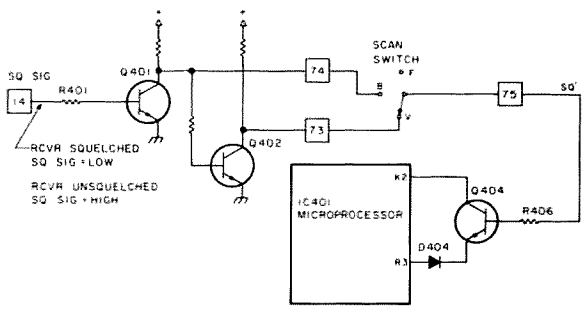

Fig. 8. Scan-control circuits before modification. Squelch activity enters board at pin 14 and arrives at scan-control switch Q404 either inverted or normal or not at all, depending upon the position of the scan switch. Scanning is stopped while Q404 is turned on; it resumes when turned off.

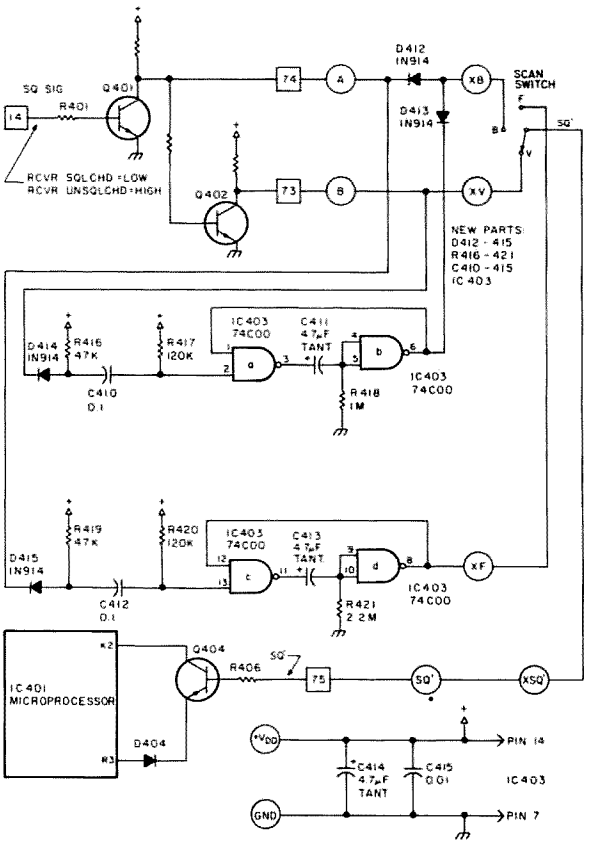

Fig. 9. Scan-control circuits after modification. Numbers in squares refer to existing control-board pin or pad numbers. Numbers in circles refer to inputs and outputs on the new board. IC403A and B and IC403C and D are wired as monostable multivibrators triggered by D414 and D415, respectively. Squelch activity enters through pin 14, upper left. Scanning is stopped while Q404 is turned on; it resumes when turned off, lower left.

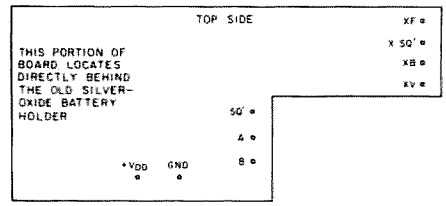

Fig. 10. Constructing the new scan-control circuits on a board this size and shape will allow them to fit neatly inside the control head between the control board and the potentiometer mounting board. The board is shown here as it would be viewed looking from the front of the Azden, down through the existing control board.

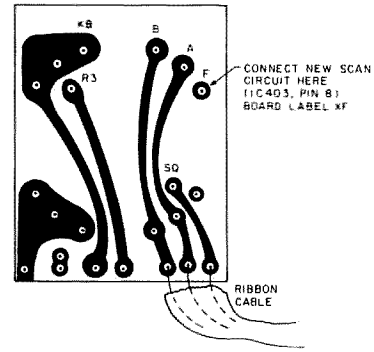

Fig. 11. Rear view of scan-mode switch showing point of connection from new scan circuit.

low is applied through D414 to the trigger-pulse generator made up of C410, R416, and R417. This trigger pulse is applied to pin 2 of the pulse generator, beginning a 2.5-second low pulse that keeps the scan stopped through D413. If the channel is still vacant when this pulse generator times out, the scan will begin again.

When the F or sample mode is chosen, an active channel again pulls the collector of Q401 low; this low is fed through diode D415 to the trigger-pulse generator composed of C412, R419, and R420. This triggers a 5-second low-going pulse which is fed through to the SQ' line and stops the scan. When this pulse times out, the scan begins again even though the channel is still busy. The reason for this is that the trigger-pulse generator, C412, has not reset and therefore cannot retrigger the holding pulse until the receiver restarts its scan.

With the parts values shown, the hang time is about 2.5 seconds and the sample time is about 5 seconds. These times can be altered by changing R418 (hang time) or R421 (sample time). Be sure to use tantalum capacitors for C411 and C413; other types may be too leaky to allow reliable operation. Do not substitute TTL NAND gates; the input impedance is substantially different and the timing will be completely wrong. Other CMOS NAND gates such as the CD4011 may be substituted, but be careful: The pinout will not necessarily be the same. The decoupling capacitors, C414 and C415, may not be necessary; they reflect my purist attitude in good circuit design.

The sample mode of scanning is implemented by using the old "free-scan" position of the scan switch. The output of the sample-mode pulse generator (IC403 pin 8) is fed to the unused switch terminal labeled F, as shown in Fig. 9.

Component layout is not particularly important for this circuit; the only real criterion is that the finished circuit fit within the confines of the control head. I used printed circuit techniques on an L-shaped board as shown in Fig. 10. This simple circuit can very easily be made by hand-painting the board using a small brush or resist pen. Vectorboard wiring is also a viable alternative. Even wire-wrap techniques could be used if the pins were limited to level-two height. After the circuit has been constructed, interconnect it to the control head as follows (see Fig. 10):

1) Connect a 3-inch twisted pair of wires to the new board at +Vdd and ground.

2) Connect a 3-inch twisted triplet of wires to the new board at SQ', A, and B.

3) Connect a 4-inch wire to the new board at XF.

4) Locate C403, a 470-μF electrolytic mounted on the foil side of the control board under the processor chip.

5) Solder leads +Vdd and ground across the leads of C403; observe polarity.

6) Locate the three-wire ribbon cable that comes from control-board points SQ', A, and B. Unsolder this cable from the control board and resolder it to the new board as follows: what was soldered to SQ', A, and B on the control board now connects to XSQ', XB, and XV on the new board, in that order.

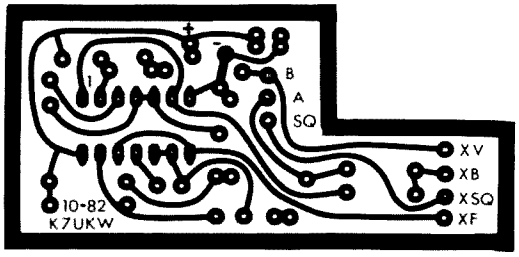

Fig. 12. PC board.

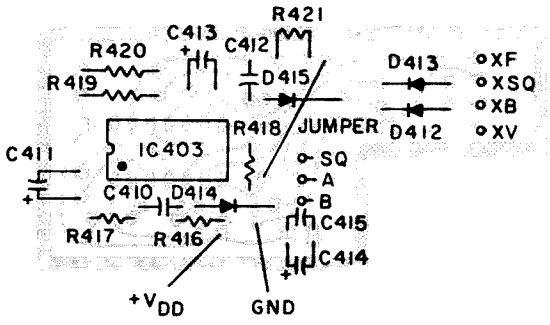

Fig. 13. Component layout.

7) Solder the triplet of wires to control board points SQ', A, and B from the identically-designated points on the new board.

8) Solder the wire coming from point XF on the new board to the unused point F on the scan-mode switch's printed circuit board, as shown in Fig. 11.

After all connections have been made, wrap the board completely with electrical tape or heavy kraft paper to eliminate any possibility of short circuits. Now gently guide the board into the space between the existing control board and the potentiometer mounting board, keeping it well to the left side, directly underneath the old silver-oxide battery holder. Fold the connecting wires neatly into place beside and underneath the new board. The stiffness of the connecting wires and the ribbon cable serve to hold it in place adequately; no special mounting is really necessary.

Now solder the nicad battery in place as discussed previously, making sure that it is wrapped sufficiently so that it will not become pierced when crammed into the confines of the control head. The battery fits vertically in the space directly behind the scan-mode rotary switch. Remember, the external speaker jack was removed to make room for this.

Before sliding the battery in place, try to smooth up the rear solder connections on the PC board for the scan switch by snipping the sharp lug ends flush, using semi-flush-type diagonal cutters, a sharp knife, or similar tool.

Caution— be very careful not to drop clippings, filings, or bits of solder into the control head; hold the unit upside down when smoothing up these connections!

Now slide the battery into the space provided and reassemble the control head. The top plate with the bit of foam rubber on the inside mounts so that the foam is pressing on the old battery holder. A piece of electrical tape over the battery leads on the old holder will eliminate any possibility of a short to the cover.

Testing Your Work

Plug the control head and the main chassis back together and hook up power and an antenna. Turn on the main power switch and write several of your local repeaters into the memory. If you don't have that many repeaters, write in anything; right now we just want to make sure the memory backup is working. Now turn off the power and go have a cup of coffee.

After five or ten minutes, turn on the power again. Check the memory; all should be as it was before the power was killed. Now move the scan switch to the right-hand V position. Press the MSCAN button on the front panel. The receiver should stop at the first vacant channel encountered and stay there until the channel becomes active. Now advance the scan switch to the B position. If the receiver is not scanning, press the MSCAN button again. The receiver should stop on the first busy channel and stay there until it clears. It should then remain there an additional 2.5 seconds (approximately) before scanning resumes. Now switch the scan mode to F. This is the sample-scan position. The receiver should scan for a busy channel as before; however, after it lands on an active channel, it will stay there for only about 5 seconds and then resume scan automatically.

Now place an offset into the memory—either plus or minus will do. Watch the display and throw the reverse switch on the microphone. The display should change to the offset and the receiver will follow the display.

If a sensitive current meter is available, the standby current drain can be measured; it should be less than one microampere with the power switch off and the power cable connected to a source of 12 volts. Typically, it will read less than 0.1 microampere.

Troubleshooting

No memory backup could be due to a discharged memory battery; a fully-charged battery will read about four volts with a typical VOM. Anything over three volts should still hold the memory. Recheck the battery polarity; the control board has a plus and minus silkscreened near the old holder.

Too much standby current drain could be due to several problems. The only reliable way of finding out which is to trace the wiring step by step and isolate each possible load until the bad one is found. Begin by verifying that every circuit except the rf PA board is connected to the cold side of the power switch. Next, disconnect the power from the rf PA board (pull plug P301). The PA is located on the bottom side of the main chassis at the rear and is connected to the hot side of the power switch.

If the reverse switch doesn't work, check that it really is switching a ground all the way back to the control board; check that the polarity and location of D411 are correct.

A problem with the scanning modification must be either in the new board or in the connections to it (assuming the scanning worked properly prior to the modification). The pulse generators can be checked with a VOM by watching their outputs and pulling the trigger inputs low; with a grounded clip lead, touch the anode side of the trigger diodes. Check the polarity of D412 and D413. Check the wiring between the boards and scan switch. Make sure the correct F point on the scan switch was used (there are two points labeled F on the scan-switch PC board; Fig. 11 shows the correct one).

These modifications should give you even more enjoyment from an already superb piece of communications equipment. ■

VIC RAMification: Part III

Thank W6LOB for the memories.

In my previous article, "VIC RAMification: Part II," which appeared in the January, 1985, issue of *73* Magazine, I mentioned an alternate procedure for VIC-20s using 2K-by-8 RAM chips. Later versions of the VIC-20 have a greatly reduced chip count. Where there had been eleven 2114 1K-by-4 RAM chips, there now are only three. Two of the remaining 2114s are used for the lowest 1K block of RAM (including page zero) and the third is for color memory. The eight missing 2114s have been replaced by two 2K-by-8 chips. I used HM6116s in this second procedure. I believe that TMM2016s will do as well.

I would also like to apologize for an error I committed in the first article. Wherever I made reference to pins 4, 5, and 6 of the 74LS133, it should have been to pins 5, 6, and 7. This error occurs in Table 1, twice in step 5, and once in step 7 of the procedure section.

The theory of operation remains the same as specified in the earlier article. The list of materials and tools is changed only by the substitution of two HM6116-4s for the 2114s. The 6116s can also be obtained from JDR Microdevices, 1224 S. Bascom Avenue, San Jose CA 95128, for $4.75 each. The major change is to the procedure section. The newer VIC-20 has a much different parts layout and a much narrower board. Despite this, its basic functions remain unchanged.

Procedure

1) Open up the VIC. There are three Phillips screws under the front edge of the VIC. Remove these and gently lift the front. The case is hinged at the back. Unplug the keyboard cable and the power-indicator lamp cord.

2) Locate the 6116s. (See the previous article if your VIC uses 2114s.) The 6116s are directly in front of the 6522s and are designated U15 and U14. They are 24-pin chips, and regardless of the number on the top of them, they are equivalent to HM6116s. You may ignore the three 2114s which are directly to the right of the 6116s.

3) Locate the chip-select gate, the 74LS138, which is second from the left in the row of chips directly below the expansion connector. Its designation is UC4. It is used as an address decoder providing chip-select signals (low) for each 1024-byte piece in the first 8192-byte block, which we could call BLK0. We are interested in the select lines for RAM1, RAM2, and RAM3. These signals travel to the expansion connector and also to the data-bus control chip, the 74LS133, designated as UD9.

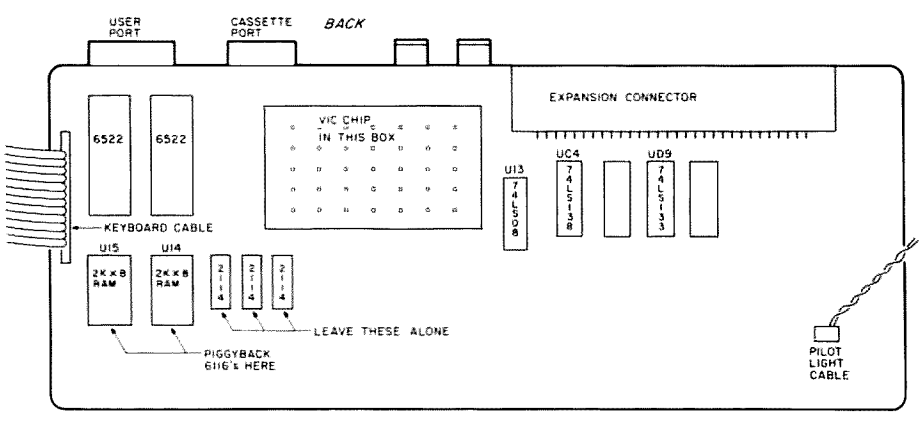

Fig. 1. Inside the VIC-20. Piggyback your new memory only where shown.

4) Locate data-bus controller UD9. This chip is located fourth from the left in the row below the expansion connector. Table 1 shows the connections of the chip-select signals. It would be wise to verify the specifications presented here with a VOM.

5) Cut traces. This step is taken to stop the VIC from shutting off the data-bus transceiver when RAM1, RAM2, or RAM3 are accessed. To cut the traces you must first remove the VIC board from the case bottom. It is attached to a metal carrier by three small machine screws and by solder tabs. Remove the metal carrier from the case bottom, and then remove the carrier from the VIC board by heating the solder tabs and prying them up.

Remove the three small machine screws, and the board is free. The traces to cut are at pins 2, 3, and 11 at UD9, at pins 12, 13, and 14 of UC4, and at pins 14, 15, and 16 at the expansion connector. Also cut the traces between pin 1 and pin 2 and between pin 2 and pin 7 of U13 (74LS08).

Use the X-acto® knife for this task. *Here are two warnings!* First: When you turned the board over, the relative position of the pins changed. What was once on the left is now on the right. Be extra careful that you are cutting the correct traces. Second: Make two cuts very close together and pry out the tiny chunk of copper, and don't let it get under any of the chips. Wet the end of

	(UC4) 74LS138	(UD9) 74LS133	Expansion Connector

RAM2	pin 13	pin 3	pin 15
RAM3	pin 12	pin 2	pin 16

Table 1.

your little finger and remove the scrap from the board.

Now, using a short piece of stripped wire-wrap wire, connect 74LS133 pins 2, 3, and 11 to 74LS133 pin 16. This will ensure that these three inputs will stay high, being tied to plus five volts. Connect pin 12 of UC4 (74LS138) to pin 1 of U13 (74LS08). Connect pin 13 of UC4 (74LS138) to pin 1 of U13 (74LS08). Verify these new connections (and disconnections) with the VOM.

6) Install 6116s. This step takes the most time. We are going to piggyback two new 6116 RAM chips on top of the on-board 2K-by-8 RAM chips. Make sure that all the pins on the new 6116s are parallel. Test-fit them on the on-board RAMs. The new chips should fit snugly without forcing.

Locate the chip select (pin 18) and the output enable (pin 20) on each of the new 6116s and bend them outward until they are ninety degrees to the other pins. Put each chip into the third-hand vise and lightly tin the inside of each of the pins. Place the two new 6116s piggyback on the on-board RAM chips.

Leave some breathing room between the on-board chip and its piggyback partner. Be sure you have oriented the new chips correctly. Pin 1 on these chips generally is indicated by a notch on one end. Pin 1 should be at the upper left-hand corner.

Tack-solder each chip to pins 1, 13, 12, and 24. These are the pins on each of the corners. After each chip has been tacked on, briefly touch each pin's junction with the soldering iron for all the rest of the pins. Check continuity of pin 1 of the new chip to pin 1 of an on-board chip without a piggyback partner. Do this for each pin with the exception of pins 18 and 20.

Note any pins showing an open circuit. Use the tip of the X-acto knife to gently push and hold the pin while applying the soldering iron. Retest the continuity with your VOM.

7) Prepare the chip-select lines which will connect each 6116 to the chip-select outputs. Connect pins 18 and 20 of one 6116 to pin 14 of UC4. These connections are made on the top of the board.

Connect pins 18 and 20 of the other 6116 to pin 3 of U13 (74LS08). Pin 14 of UD4 is the RAM1 select signal. We are using only half of the 6116 connected to RAM1. RAM2 and RAM3 are ORed by the 74LS08 to develop the chip select for the other 6116.

How can an AND gate perform an OR logic function? There is a theorem which states: A positive-logic AND is a negative-logic OR. Pin 3 will be high when RAM2 and RAM3 are high; that is, neither is active. Pin 3 will be low, selecting the 6116, if either RAM2 or RAM3 is low.

Check the continuity of these connections with the VOM. Now make a *non-continuity* check to ensure that the RAM1, RAM2, and RAM3 select lines are NOT connected to pins 11, 3, and 2, respectively, of the 74LS133.

8) This completes the hardware modifications. Before you put your VIC-20 back together and plug it in, here are some items you should check very carefully.

- First, are there any loose chunks of solder or bare wire lying around on the board?
- Second, are there any solder bridges between pins on the piggybacked RAM chips?

The third point may sound silly. It isn't. In the modification described in my previous article, I installed one of my 2114s backward. I found out during testing.

- Be sure your 6116s are all pointing north, as it were.

After your work passes this visual inspection, reinstall the board in the case bottom.

9) Button up the VIC. Screw the board to the shield carrier and bend the tabs over. After testing is complete, resolder the tabs to the board. Attach the carrier shield with the circuit board to the case bottom. Do not get the screws for mounting the board mixed up with those for fastening the case bottom to the case top (keyboard).

Hinge in the case top; connect the keyboard plug on the left and the power-on light plug on the right. For initial testing, you may want to leave the case top free or even off to the side a little. For final assembly, fasten the case top to the bottom with the three long screws.

Testing

Please refer to my January, 1985, article in *73* for the sections on testing and moving the screen. Basically, when you power up your VIC-20 after this modification, you should receive the message "6655 BYTES FREE." I had neglected to cut the trace connecting pin 14 of UC4 to pin 11 of UD9, thereby depriving myself of 1024 bytes of added memory. A couple of swipes with the trusty X-acto and all was well. ■

Yesterday's Circuits Today

Remember tubes? W6HDM does. He's resurrected a half dozen of his favorite circuits and updated them with semiconductors.

Irving M. Gottlieb W6HDM
931 Olive Street
Menlo Park CA 94025

Various circuits and techniques have had their day in the sun, only to be relegated into near oblivion by advancing technology, changing economic priorities, or by being somewhat less than practical; this has been true especially during times when the supporting technology was not that great. In electronics, as in other endeavors, the quest for better performance, higher efficiency, and reduced cost has evoked interesting schemes for squeezing more blood from the turnip. (Indeed, some innovators must have originally had perpetual-motion precepts on the mind.) It should, in any event, prove rewarding to review a few of these ideas and implementations. It is just possible that with modern devices and components, new life may be infused into an obsolete technique. Also, as is often the case, one thing leads to another and new concepts evolve from previous methods of problem solving.

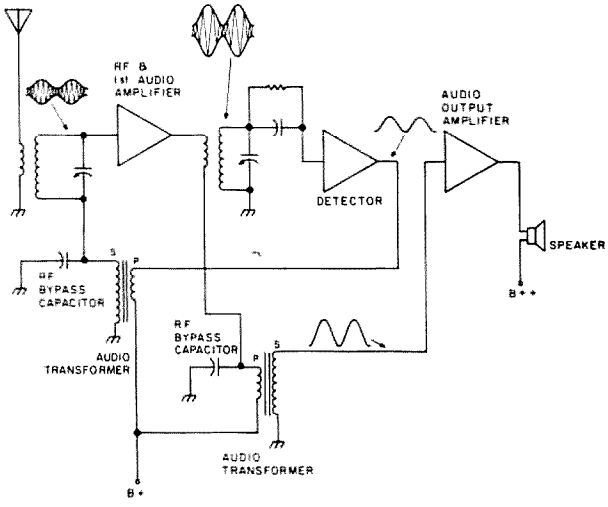

Fig. 1. Basic functional diagram of the reflex receiver. Although the stages were originally configured around tubes, it should be feasible to use solid-state devices such as transistors, FETs, or ICs.

The Reflex Receiver

A noteworthy example of yesteryear's pursuit of something for nothing was the reflex radio receiver. In its original and most prevalent form, a tuned rf receiver was so configured that an rf amplifier stage—usually the first—also served as the first audio-frequency stage. At first thought, such a concoction appears totally asinine. Common sense tells us that such a set would necessarily be plagued with all kinds of feedback problems and instabilities. Actually, how-

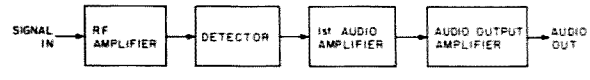

Fig. 2. Block diagram of equivalent receiver to the setup shown in Fig. 1. This is a conventional (unreflexed) system utilizing four amplifying devices instead of the three which sufficed for the reflex receiver. More complex reflexing arrangements can be used to eliminate additional stages.

ever, reflex radios were "hot" performers and there was generally nothing to distinguish their performance from more conventional circuits except that a three-tube reflex set would, indeed, exhibit four-tube capability. Even those reflex circuits which also included regeneration operated quite stably. Let us see why, our first intuitions notwithstanding, reflexing proved a feasible technique.

The schematic of a reflex set is shown in Fig. 1 and the block diagram of the equivalent receiver is shown in Fig. 2. It is easy enough to see that the rf stage also performs as an audio driver stage, but a little explaining is in order to illuminate how this is possible.

In order for an amplifier, be it tube, transistor, or IC, to process two different frequency bands without interaction between them, two requirements must be met. First, amplification must be *linear* so that no "mixing" or heterodyning occurs. This is readily complied with by ascertaining that the amplifier always operates in its class-A mode. Second, the frequency bands should be sufficiently different so that the outputs of the reflexed amplifier can be channelized easily to where they are supposed to go, and so that it is easy to get rid of frequencies that try to go into wrong places. This is accomplished easily in broadcast-band reflex radios because of the great difference between broadcast carrier frequencies and audio frequencies. Resonant tank circuits eliminate audio frequencies, and simple bypassing to ground eliminates straying radio frequencies.

The Regenerative Modulator

The regenerative modulator is a novel and unique circuit. Its mystique is enhanced by its very name—it is not a modulator with positive feedback unless you are prepared to stretch words a bit. A better name would be stimulated oscillator, or subharmonic generator, for that is what actually takes place: An input signal provokes an output at an integral submultiple of the input frequency. Granted, this is commonly accomplished with cascaded flip-flops. For example, a digital watch contains such a frequency divider for reducing the nominally-32-kHz crystal-oscillator frequency to one Hertz. And, of course, similar digital-divider systems are used in frequency counters, phase-locked loops, digital multimeters, and elsewhere.

The regenerative modulator is different in an interesting way. It is an "analog" circuit that operates from and produces a sine wave! It is capable of preserving either FM, SSB, or AM modulation. Regenerative modulators probably originated in the carrier-telephone industry, and it appears that the circuit was used more in England than in this country. At one time, hams used it and similar circuits to get crystal control on 160 meters (when only 80-meter crystals were available).

The basic principle of the regenerative modulator can be understood by referring to the block diagram in Fig. 3. It takes a little brain work to see what actually goes on. Once the theory of operation is mentally digested, you are certainly going to be heard exclaiming, "Now why didn't I dream that up?"

The circuit depends for its behavior on two nonlinear amplifiers and two bandpass filters. The first nonlinear amplifier is very similar to a mixer stage in a superhet: It samples two input frequencies and delivers a difference frequency. This difference frequency happens to be the *output frequency* of the circuit and is supported by the first bandpass filter or tank circuit.

The second nonlinear amplifier is very similar to the frequency multipliers commonly used in transmitters, although it usually is biased close to class-B rather than class-C operation. The harmonic output of this stage is supported by the bandpass filter or resonant tank in its output circuit. Finally, this harmonic frequency is *fed back* to the mixer stage. In order to visualize what happens, it should first be driven home that absolutely nothing transpires without input signal f_{IN}. Thus, despite the feedback loop and the apparent opportunity for interaction between the stages, the circuit remains inoperative with no input signal. Feedback notwithstanding, the tuned circuits are not appropriate for self-oscillation. Now, let's see what takes place when an input signal of the right frequency is applied to the regenerative modulator.

It is probably easiest to follow the operating sequence by referring to an actual circuit rather than to a block diagram. For this purpose, consider the tube version shown in Fig. 4. Inasmuch as original applications of regenerative modulators were implemented during the heyday of the

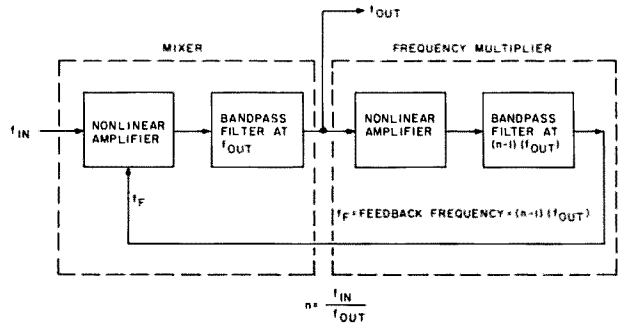

Fig. 3. Block diagram of the regenerative modulator. The amplifiers can be either tube or solid-state devices. The bandpass filters can be simple parallel-resonant circuits. The basic function of this arrangement is that of a frequency divider. Unless the proper frequency is applied to the input (f_{IN}), there is no output.

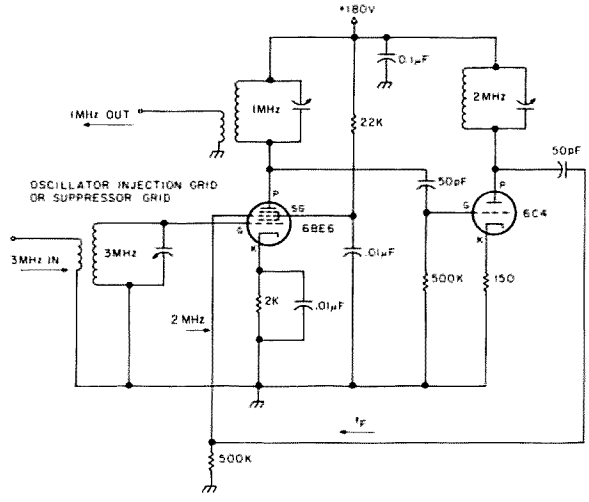

Fig. 4. An experimental tube version of a regenerative modulator. Strong drive is needed so that the tubes are operated in their nonlinear regions. The first tube can be any of a variety of multi-grid tubes such as converters, pentodes, etc.

vacuum tube, this tack has a natural relevancy. Once the tube circuitry is understood, no new concepts need be dealt with in grasping the performance of solid-state counterparts of the scheme.

With regard to the tubes used in Fig. 4, almost any other tubes can be made to work equally well. It is, however, particularly convenient to use one multi-grid tube, such as a converter or a pentode with external connection to the suppressor grid. The reason for this is that the first tube is required to output a difference frequency resulting from inputs impressed with *two* frequencies, the input frequency and a fed-back frequency.

Note in Fig. 4 that the input frequency is 3 MHz, which is applied to the control grid. Next, postponing explanation for the moment, it can be observed that the suppressor (or any other grid of a multi-grid tube) is impressed with a frequency of 2 MHz. That being the case, it follows that the 1-MHz tank circuit in the output of this stage serves to optimize the 1-MHz beat frequency produced by nonlinear interaction of the input frequencies within the tube. This, of course, is similar to the operation of mixers in superheterodyne receivers. In this particular application, however, we naturally ask what keeps the process going—in other words, why should the 2-MHz input obligingly appear?

The neat little trick that is used utilizes the second tube as a frequency multiplier. It is driven by the 1-MHz frequency we already *assumed* was generated by the first tube. The resonant tank in the output circuit of the frequency-multiplier tube supports the required 2-MHz feedback frequency.

But that is where we came in! Admittedly, a little trickery was indulged in this explanation because it was assumed that the circuit was *already* performing and then we proceeded to show *why* this could, indeed, be. It's simple enough, but experimentation with drive levels and biasing are in order for best results. Also, it should be appreciated that one cannot just throw in any old resonant circuits or apply any arbitrary input-signal frequency. These all have to be related according to the equations depicted in the block diagram. Once this relationship is obeyed, numerous frequency ranges and division ratios can be accommodated, however.

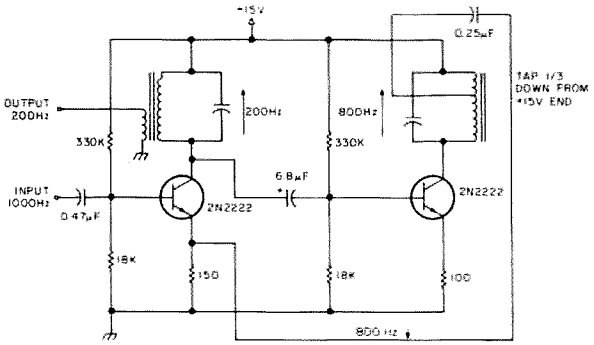

Fig. 5. An experimental transistor version of a regenerative modulator. Although this example circuit operates at low audio frequencies, the basic idea is applicable to radio frequencies as well.

The transistor version is shown in Fig. 5. In this instance, the regenerative modulator operates at audio frequencies. Essentially the same principles prevail as with the tube circuit.

The Synchronous Rectifier

Although the notion of synchronous rectification is as old as the hills, don't be too surprised to find its implementation in some of the most sophisticated modern power supplies. Its basic concept is simple enough—by applying the appropriate signal to the control element of an amplifying device such as a tube or transistor, you can make it conduct for the better part of just one polarity of an applied ac wave. In other words, you have accomplished rectification. It so happens that the enabling signal must be applied to the control element in *synchronism* with the wave you wish to rectify; therefrom stems the term "synchronous rectifier." The question before the house is *why* do it this way when we have no end of specialized diodes specifically designed for use as rectifiers?

The quick answer is that the synchronous rectifier is capable of developing appreciably less forward voltage drop than conventional silicon diodes when they were the last word in rectification efficiency. But the bottom line is that the synchronous rectifier can, in some cases, compete favorably with the modern Schottky diode in the matter of forward voltage drop. And, at least for low-frequency work, the synchronous rectifier tends to be more economical to use in production equipment.

In order to grasp the significance of the "resurrected" synchronous rectifier, it should be understood that, with bipolar transistors, its application is limited to low-voltage (say five volts), high-current power supplies. And it is frequency-limited to something in the mid-audio range, at best. No pretense is made that is usable for 20-kHz square waves. But for 60 Hz, its rectifying efficiency can be superb. It is feasible to rectify 25 or 50 Amperes and incur a forward voltage drop on the order of ¼ volt, or less.

Before we go any further, it must be explained that the synchronous rectifying element we have been talking about is none other than the germanium power transistor. If you thought this

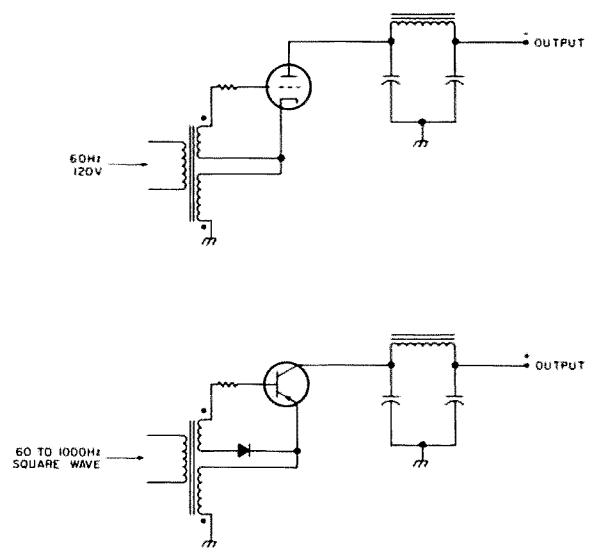

Fig. 6. Tube and transistor versions of the synchronous rectifier: Tube circuit (top) did not provide any noteworthy performance features; transistor version is capable of high-efficiency rectification for high currents and low voltages because internal voltage drop can be much less than for ordinary rectifier diodes.

device was extinct, think again—there remain several semiconductor manufacturers that still make germanium power transistors. And the *synchronous rectifier* is one of the applications they are pushing. This all comes about because $V_{CE\ (sat)}$ for these devices is only about 0.2 volts. Note that this is much less than the 0.65 volts or so for the silicon rectifying diode. For high currents, it is also less than the voltage drop produced by germanium rectifying diodes. If you are rectifying five volts at several tens of Amperes, a few tenths of a volt can be very significant in terms of dissipation and efficiency.

The synchronous rectifier has had its ups and downs. In its tube version, it never really had much to offer—there was no particular advantage in most cases in using it in lieu of conventional rectifier circuits. And in solid-state practice there have been myriads of dedicated junction rectifier diodes available for service in simple rectifier circuits. Nonetheless, we find that power-supply engineers have found a new virtue in this old technique.

Roughly analogous tube and transistor versions of half-wave synchronous rectifiers are shown in Fig. 6. The tube version is duck soup to implement because nothing bad happens when the plate polarity reverses. In the transistor version, precautions have to be taken to prevent reverse load current from finding a conductive path back to the emitter. Otherwise, the fact that the output polarities of the rectified current are different in the two circuits is not significant—it comes about because the tube is an NPN device and the power transistor shown is PNP.

Semiconductor firms are now developing special power-MOSFET devices for synchronous-rectifier service at higher voltages and higher frequencies.

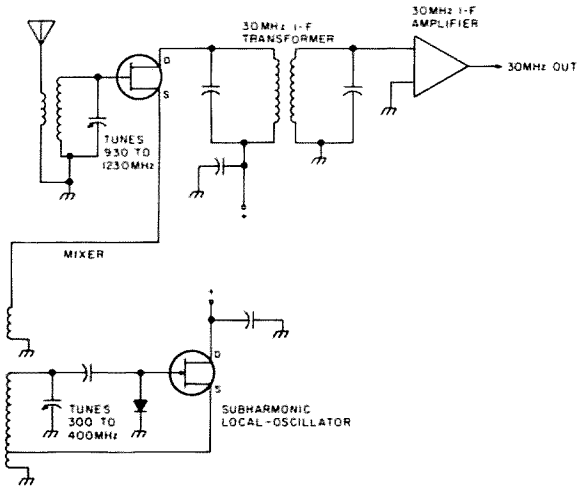

Fig. 7. Simplified circuit of the "business end" of a superhet, with subharmonic oscillator. Contrary to common assumption, the oscillator does not *provide harmonics of its fundamental frequency. Rather, the needed frequency multiplication takes place in the mixer.*

The Subharmonic Local Oscillator

An interesting circuit technique that has been in and out of fashion over the years is the submultiple or subharmonic local oscillator in a superheterodyne receiver. Basically, the scheme consists of using an oscillator with some fraction of the needed frequency in order to convert the incoming signal to the proper i-f band. This being the case, it often has been erroneously supposed that this is feasible by virtue of the harmonics generated by the oscillator. To see that this is not the *modus operandi*, one must appreciate the reason such an arrangement is used in the first place.

In UHF and microwave applications, it is not always easy to obtain the desired frequency stability from the local oscillator. If, however, the oscillator could operate at one-half or, say, one-third of the needed frequency, the stability problem tends to be greatly alleviated. However, it is also true that really stable oscillators produce nearly pure waveforms, i.e., sine waves without much harmonic energy. So for this reason the commonly assumed "harmonic output" from such oscillators is incorrect. But without harmonic generation, how can such an oscillator perform its intended frequency-translation function in the mixer stage of the receiver?

Here we must delve a bit into the mathematics of heterodyning. It turns out that with a certain proviso, an appropriate mixer or converter stage can produce beat frequencies according to the relationship: $f = w \pm nq$, where w is the incoming signal frequency (from the antenna), q is the local-oscillator frequency, and n is any whole number. This being the case it is a straightforward matter for selecting the desired i-f via resonance in the i-f transformer windings.

The proviso for this scheme to work is that the mixer or converter must have a transfer characteristic described by an exponent greater than 2. When this stipulation is met, that is, when the mixer is sufficiently nonlinear, the needed harmonics are generated *in the mixer*. Accordingly, a harmonic-rich oscillator is *not* needed.

The overall result is similar to what one might obtain from an oscillator with harmonics, but the design of the oscillator is facilitated because pure-wave oscillators tend to be more stable than those producing harmonic-rich waveforms. (Also, this technique circumvents troubles with "birdies" and spurious responses which would result from an oscillator rich in harmonics.)

Fig. 7 shows the simplified circuit of a superhet-receiver front end in which the local oscillator covers a frequency range which is only one-third as high as would be needed in the "conventional" approach. Despite the fact that the oscillator frequency is this low, the same range of signal frequencies is responded to as when conventional oscillator frequencies are used. It is as if a frequency multiplier (a tripler, in this case) were inserted between the oscillator and mixer. Indeed, such a frequency multiplier would accomplish about the same objective—permitting higher oscillator stability to be attained because of lower oscillator frequency. As pointed out, however, both frequency multiplying and heterodyning are readily accomplished within a sufficiently nonlinear mixer stage.

The FET mixer of Fig. 7 is only marginally nonlinear enough for the purpose and does not produce high conversion gain. A bipolar transistor would be better in this respect, but the FET circuit tends to be superior in signal-to-noise ratio. In either case, oscillator drive is critical for optimum performance because the requirements for harmonic generation and heterodyning are not quite the same. Although this circuit fell out of favor with the advent of high-frequency transistors, there has been renewed interest as experimentation is carried out for satellite communications equipment. Additionally, the technique is not uncommon in millimeter radar and communications technology.

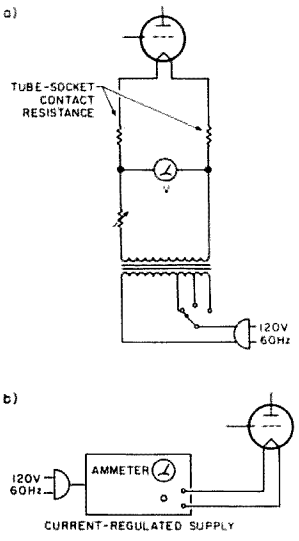

Fig. 8. Traditional and proposed methods of lighting up your transmitting-tube filaments: (a) the "good old way" and manually-adjusted voltage across tube socket may not have been so good after all; (b) proposed technique.

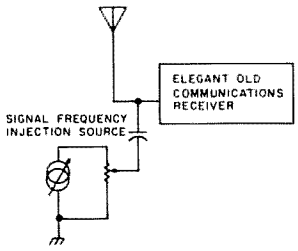

Fig. 9. Signal-frequency injection technique for SSB reception using an older receiver. The signal-frequency source is adjustable in frequency and in amplitude.

Transmitter-Tube Filaments and a Better Way to Fly

For many years the ham has been admonished by tube makers to maintain the filament *voltage* of his transmitting tubes within a prescribed range. For optimum performance and life span, this range is often cited as plus or minus five percent. This hasn't always been readily feasible for a number of reasons. The variations due to swings in the utility voltage and those accompanying key-up and key-down operation can easily fall outside of this narrow tolerance. And it goes without saying that the accuracy and readability of analog voltmeters have often contributed to an illusion of adherence to specified operation. There are also a couple of other matters pertaining to constant-voltage operation of tube filaments that, in this author's opinion, have not been accorded deserving discussion in the past.

First, the technique of measuring filament voltage by connecting the voltmeter across the tube-socket terminals can be responsible for errors of several percent even if one uses a modern high-precision digital meter. This pitfall stems from the contact resistance between the socket and the tube pins. Under best conditions (a low-current filament, a new high-quality socket, and a clean, dry atmosphere) there will be a negligible difference between the measured voltage and the voltage actually applied to the filament. But under average to worst conditions (a high-current filament, a not-so-wonderful socket that has seen a bit of service, and a polluted and/or moist atmosphere) the voltage indicated by the meter will be more than that actually getting to the filament leadwires within the tube.

The very worst situation is usually with high-current, low-voltage filaments in high-power tubes, for then the voltage drop due to contact resistance tends to be an appreciable percentage of the intended or specified voltage. Contact resistance unfortunately varies with spot temperature, contact pressure, and with surface conditions of the contacting metals. Corrosion may or may not be obvious.

The second matter has to do with the *basic notion* of maintaining a near-constant filament voltage. In perusing older literature on tube operation, I found that it appears that the true objective is to maintain a prescribed near-constant *current* through the filament. After all, thermionic emission is dependent upon filament temperature, which is more directly a function of current than of voltage. This may seem like splitting hairs, but it will be shown that better operating conditions and, very possibly, better tube life can accrue from this nontraditional approach. Indeed, one of the rewarding things about reviewing older circuit techniques is the realization that they can be either resurrected or improved using modern technology and practices.

If you are willing to buy the current-dependent concept of filament operation, the next step should almost suggest itself—the use of a current-regulated dc supply. One answer to why such a technique did not gain footing with yesteryear's hams is that a high-current regulated-power supply suitable for powering tube filaments was not an easy thing to build in pre-solid-state days. Its initial cost as well as its bulk and low efficiency would certainly have proved discouraging. Today, it is a trivial matter to construct inexpensive and compact regulated supplies. One also has the choice of using the series-pass "linear" approach, or for greater efficiency, the switching technique. Moreover, it is just as easy to make a constant-current supply as it is to make the more conventional constant-voltage supply.

One reason for going to constant-current operation has already been cited—the basic dependency of electron emission on heat-producing current. Another reason is the beautiful situation whereby the filament is caused to operate at the same temperature *despite* variations in the socket-contact resistance. That is the nice thing about a current-regulated supply—even though the overall load resistance may vary, load current remains constant! Although a voltage-regulated supply would gain us freedom from the effects of ac line voltage variation, tube-socket resistance variations would still affect the *true* filament voltage and its resulting current!

Summarizing our revamp of the traditional method of

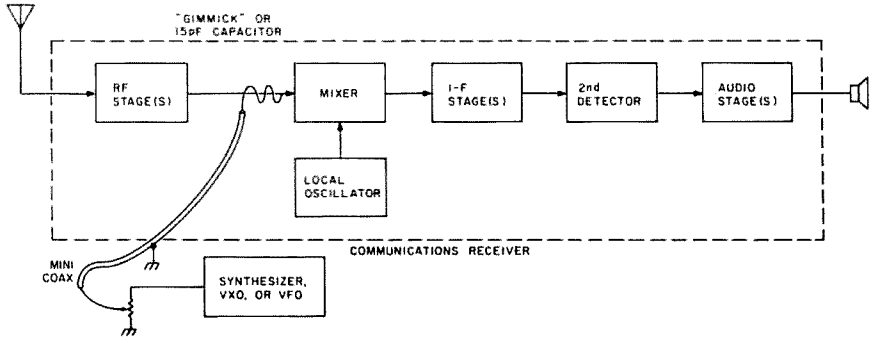

Fig. 10. A somewhat better arrangement for receiving SSB signals with an older set. In this setup, the signal-frequency injection takes place following one or more rf stages. Also, the use of a synthesizer is suggested.

powering transmitting-tube filaments, we have agreed (hopefully) to automatically regulate filament *current* and, although it has not been explicitly mentioned, we have agreed to the use of dc. Thus, a dc-current-regulated supply will be adjusted to provide a prescribed filament current and we will let filament voltage ("true" or otherwise) swing around to its heart's content. Fig. 8 compares the traditional and the proposed methods. In Fig. 8(b), tube-socket contact resistance is not shown because it is no longer a factor affecting thermionic emission.

A natural question with regard to this proposed practice is what do the tube manufacturers think about it? Not only have I been unable to extract strong opinions from them, but there has been little consistency in the meager information that has been forthcoming. For one thing, their feet are in concrete: You adjust for a voltage reading with a rheostat or autotransformer—that's simply the way it has always been done! I can't help wondering if it is subliminally suspected that the constant-current technique might lead to more widely-spaced tube replacements because of greater longevity! (Constant-current operation would do away with high-inrush current to cold filaments—a life-span-reducing phenomenon.)

Signal-Frequency Injection for SSB—An Update

An interesting circuitry technique stems from the 50s and 60s, when single-sideband communication was gaining a foothold in the ham bands. It was found that otherwise-superb receivers either could not respond to SSB signals or were very unstable when the i-f beat-frequency oscillator was used to demodulate that mode. Many hams found that a practical solution to this dilemma was signal-frequency injection. This technique simply made use of a stable oscillator to inject the missing carrier at the receiver's input along with the SSB signal itself. The scheme, in its simplest form, is depicted in Fig. 9.

An example of signal-frequency injection for the reception of SSB signals is a Hallicrafters model SX-25 receiver used in conjunction with a BC-221 signal generator, resulting in very satisfactory reception of 80-meter SSB stations. Initial tuning was done with the receiver. This served to locate the station; then the BC-221 signal generator was tuned to the missing carrier of the station, this being manifest by demodulation of the previously garbled audio which now became intelligible.

The significant aspect of this technique was that the SSB station remained intelligible for long periods of time—there was little tendency for it to slide into Donald Duck lingo. What this says, of course, is that the frequency stability of the BC-221 signal generator was exceedingly good—much better than the i-f bfo in the receiver. Interestingly, the BC-221 oscillator is self-excited. Think, then, how much better stability might be derived from a crystal oscillator.

We are rapidly homing in on an interesting design technique, resurrecting the use of signal-frequency injection. You can bet your boots that hams of that period also made use of the vxo for injecting the missing carrier of SSB signals. Of course, one of the shortcomings of the vxo is its inability to provide wide frequency coverage. This can be remedied via the use of multiple crystals and this, indeed, was also resorted to.

It so happens that many hams still have elegant old communications receivers that are capable of good SSB performance with signal-frequency injection. But today's ham has a new circuitry technique in his technical arsenal—the *frequency synthesizer*. I have not seen evidence of the use of the frequency synthesizer for such a purpose and would like to suggest it. It would appear that a very effective overall receiving system for SSB could now be implemented by the association of a frequency synthesizer with an older communications receiver. This would be yet another example where a nearly-forgotten circuit application could be profitably revived in today's ham shack.

The scheme depicted in Fig. 10 makes use of the suggested synthesizer and also incorporates a more desirable method of signal injection. Advantage is taken of the fact that many older communications receivers have one or more tuned rf stages ahead of the mixer or converter. By injecting the signal frequency at a point following one of these rf stages, radiation of interference is reduced to a negligible level. Note that the surgery required for the set remains minimal.

Of course, other refinements will suggest themselves such as optimization of time constants in the avc system and possibly the substitutions of a product detector for the one that sufficed for AM listening. But the bottom line of this discussion involves the suggested synthesizer, which either was not around or didn't fit ham budgets when signal injections were first experimented with. Although older receivers are often "boat anchors" with regard to size and weight, some are truly classic when one considers their performance. It would be a shame to relegate such a set to the scrap heap if a simple stratagem can be employed to remedy a shortcoming or two.■

Up, Down, and All Around

Fit your KDK 2016A with this ten-dollar Scan Can.

If you are the owner of a KDK 2016A, you know how frustrating it is to find those repeaters when you are on a trip. The *Repeater Directory* is of little help because I have found that a good number of the listed repeaters are no longer on the air. It takes a good amount of dexterity to manually switch through three thousand positions to find a repeater that is on the air—and even then you have no guarantee of finding one.

So why not end all that frustration and build one of these "Scan Cans"? The cost is low—less than ten dollars if you have a well-stocked junk box. The unique modular design lends itself to future expansion with other types of function modules. The circuit is simple and straightforward for ease of construction and troubleshooting.

Theory of Operation

See the schematic in Fig. 1. The clock circuit, U1, is an astable oscillator. Its frequency is determined by the combination of a 10k resistor, 100k variable resistor, and the 1-uF capacitor. The 100k variable resistor adjusts the frequency rate of the clock and the speed at which the Scan Can scans.

It is necessary to explain the terminology used for 8 volts and ground. A high (H) is +8 volts and a low (L) is ground.

The function of U2a pin 1 and U3c is to control the scan function. When U2a is high, the clock pulses on pin 2 are passed through to the input of U2c and inverted by U2c to the clock input of U4 pin 1. The function of U2c is to provide a two-phase clock for future development. When S1 is in position 1, the 100k resistor pulls U2a pin 1 to H and allows the unit to scan. When S1 is in position 3, at L, scanning stops.

In the same manner, the combination of U3c, U7b, and Q1 control the Receive Hold function of the Scan Can. Q1 serves as a buffer switch and interfaces with the receive LED of the KDK. A 2-volt potential on the base of Q1 forces the collector to go low. When U7b pins 5 and 6 are L, then pin 4 of U7b goes H. When U3b pin

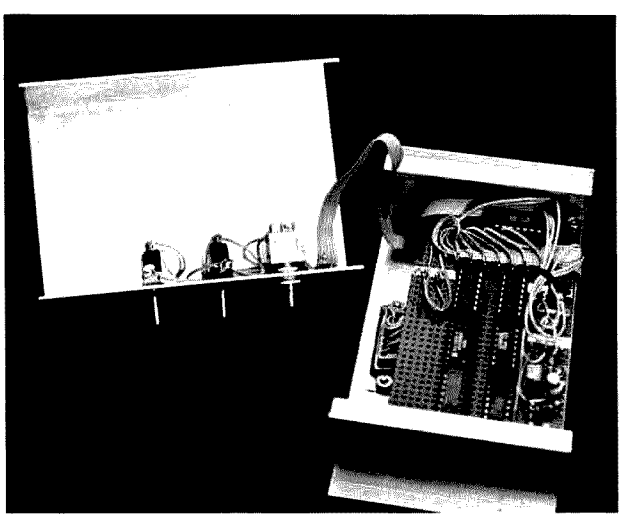

Photo A. The Scan Can showing the board layout.

Photo B. The Scan Can mounted in operating position on the KDK.

12 is H, then the counter U4 stops counting and holds. However, when zero volts is on the base of Q1, the counter resumes counting. When the scan function is in the Receive Hold condition and S2 pin 1 is placed to an L, the scan is resumed.

The BCD (Binary Coded Decimal) counter U4 has two separate 4-bit counters. One of the 4-bit counters (whose outputs are labeled A, B, C, and D) is the 10-kHz portion, and the other counter (with outputs labeled E, F, G, and H) is the 100-kHz portion. U3a and U3b are used as a decimal ten and a decimal one-thousand decoder, respectively. When both of the U3a's inputs are H, then pin 3 goes L, providing a clock pulse to the 100-kHz counter, and at the same time, U7a inverts the level and resets the 10-kHz counter to a count of zero. In the same manner, when both of the U3b's inputs are H, then pin 4 goes L and U2b pin 6 goes H, resetting the 100-kHz counter to a count of zero.

U5 and U6 are quad bilateral switches. They can best be described as eight independent single-pole single-throw (SPST) switches. When S3 is in position 3 and at H, then the switches are in the closed position, allowing the levels on the input pins to be present on the output pins labeled A^1 through H^1.

When S3 is in position 1, the outputs of U5 and U6 are switched open and the inputs will not appear on the outputs. This type of circuit is called tri-state logic. The three output-level states are high, low, and high Z.

Construction

The Scan Can shown in Photo A uses wire-wrap IC sockets and has flea clips as terminal pins. These parts are mounted on a perforated Vectorboard® that has the correct spacings for IC sockets. Other methods of interconnections may be employed because the layout of the circuit is not critical.

A 4¾"-wide by 3"-deep by 1¾"-high utility box was employed to keep the module as small as possible. D-type connectors are used because of their ruggedness and the fact that they can be used as surface-mount connectors. Five ¼" magnets are epoxied to the top of the unit to hold the Scan Can in place while connected to the KDK. This magnet attachment allows quick removal of the module when not in use or when another function module is to be used.

It is always a good idea to buzz out the wiring of the board before going any further in the construction. *Please note*: The CMOS chips used are diode-protected. However, static discharge will damage these ICs. It is recommended that you leave them wrapped in foil until you are ready to install them. After the board is completed, it is mounted in the chassis using ½" spacers. At this time the board is wired to the D connectors and the switches. I used flat ribbon cable to reduce the size of the wire bundle.

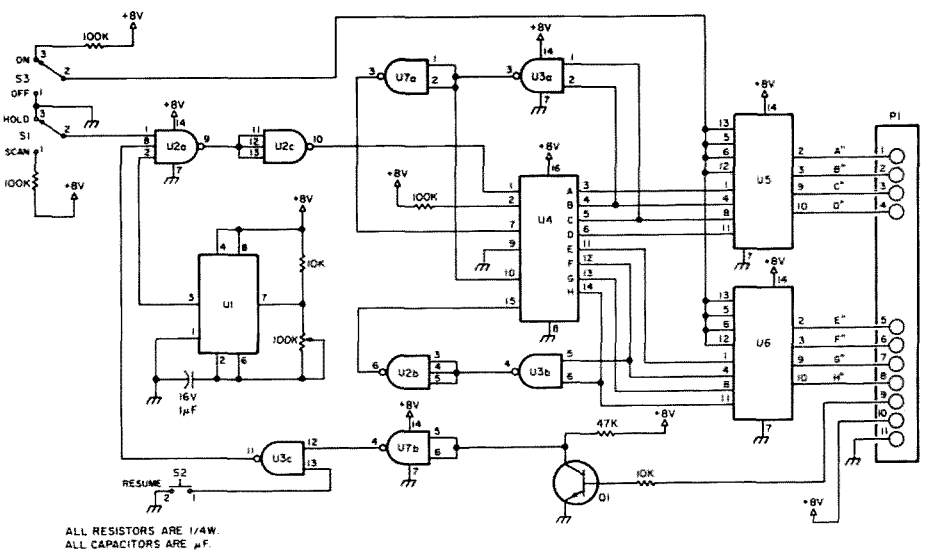

Fig. 1. Schematic of the Scan Can.

Interfacing to the KDK

Interfacing to the KDK is fairly simple and should not be too difficult for those who have worked inside the unit before. The steps taken to wire in the modification are as follows:

1) Remove both the top and bottom covers from the KDK.

2) Unsolder the speaker wires from the bottom cover.

3) With the female D connector as a guide, trace its outline on the front edge of the bottom cover. The connector should be centered ¼" from the edge. Drill holes and file to the shape of the connector. *Note:* leave the rubber pad in place and file through it.

4) Place the connector into the hole, center-punch connector mounting holes, and drill for #4 screws (a #33 drill).

5) Wire connector as per the schematic. *Note*: I used flat ribbon cable for this and the cable should be at least six inches long.

6) Mount the connector with #4-40 screws and feed the cable from the bottom close to the front panel through to the top.

7) Resolder the speaker leads and install the bottom cover.

8) Lift the synthesizer board. There are six screws holding this board down.

9) Locate IC-11 and IC-12 to determine the *location of* the proper pins that you will be soldering to (see Fig. 2).

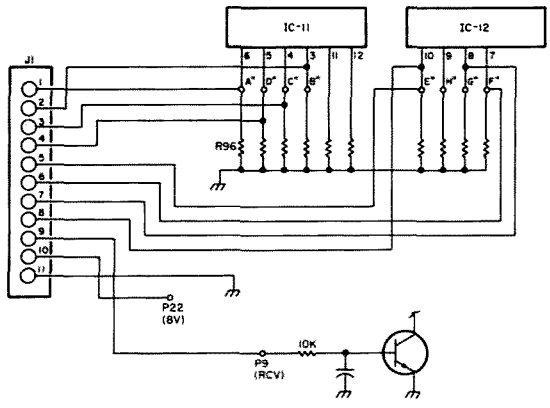

Fig. 2. The Scan-Can-to-KDK interface.

Photo C. View of the underside of the KDK. Note the positions of the connectors on the two units and the magnets.

The wires that go to these ICs are to be lap-soldered to the bottom of this board. Care should be taken that you do not overheat the pads when doing this operation. After you have lap-soldered these eight wires, inspect to see that there is no solder bridging of the adjacent pads.

10) Remount the board, being careful not to pinch the wires that you just connected.

11) Locate P9 (RCV), which is located at the rear of the board on the right-hand side. Snake the J1-9 wire through the harness to this location and solder to the pin.

12) Locate P22 (8 V), located at the lower left-hand corner of the top board. In the same manner as before, snake the J1-10 wire through the harness and solder to the pin.

13) The last wire to be connected is the ground wire. On the left-hand side of the chassis you will find a ground lug that has a capacitor connected to it. Snake the wire as before and solder it to this lug.

14) At this point in the interface wiring you should check that the wires are connected to the correct places, using an ohmmeter. After you have determined that the wiring is correct, remove the screws holding the bottom cover and install the top cover and button up. At this point you have finished the wiring required on the KDK.

Alignment

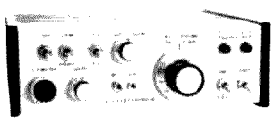
At this point you are ready to test the unit out. Care should be used when inserting the ICs. It is a good idea to ground yourself when inserting these CMOS chips. After you have inserted them and you are sure that the circuit is wired correctly, you are ready to test.

Connect the unit to the KDK and turn the KDK upside down. Have the cover removed from the module so that you can make some adjustments. On the KDK, set the memory switch to the off position. Set the main dial to zero zero zero on the LED readout. On the Scan Can, set the on-off switch to on and the hold-scan switch to scan. Turn on power to the KDK.

At this point you should see some activity on the KDK's LED readout. If you do not, turn off power and recheck your wiring. If you do have activity, adjust the 100k pot for a scan rate of approximately 100 kHz per second—or to a scan rate of your own liking. Observe that the 10 kHz is stepping from zero through nine and the 100-kHz position also is stepping from zero through nine. When these criteria are met, you are ready to go.

Tips for Operation

Operation of the Scan Can is fairly simple. However, there are tricks I have found that will help you when you operate the unit. I found that to stop on the correct channel every time I had to place the 10-kHz switch on the KDK to the 10s position. The scanner then stops on the right channel. Another thing to know is that your disc switch comes in handy when you are in doubt about the correct frequency. When you turn the on-off switch of the Scan Can to the off position, you can use the main dial as if the unit were disconnected from the KDK. When a signal locks the scanner on hold and you wish to operate on that frequency, set the hold-scan switch to hold. This allows you to transmit and receive on this channel. If you are locked to a frequency that is in use and you wish to resume scanning, press the resume button and the scanner will scan to the next frequency that is in use. ■



Parts List

U1	NE555	Timer
U4	CD4520	Dual binary up counter
U3, U7	CD4011	Quad 2-input NAND gate
U2	CD4023	Triple 3-input NAND gate
U5, U6	CD4016	Quad bilateral switch
Q1	2N2222	Transistor
P1	DA15P	D-type connector
J1	DA15S	D-type connector

AMATEUR TELEVISION

NEW 70 CM ATV TRANSCEIVER

ALL YOU NEED IN ONE BOX

$299 delivered
TC70-1

- **FULL COLOR, SOUND, & LIVE ACTION** just like broadcast TV. Get on this exciting amateur video mode at our affordable ready to go price.
- **WHAT IS REQUIRED FOR A COMPLETE OPERATING SYSTEM?** The TC70-1s downconverter outputs to any TV on ch 3 for receiving. Connect a good 70 cm antenna and low loss coax. Plug in any composite video source you want to transmit. Camera, VCR, computer, etc. Plug in any low Z dynamic mic or use color camera mic for Standard 4.5 mHz TV sound. Connect to 13.8 vdc for base, mobile, or portable. See chapt. 20 1985 ARRL Handbook. That's it!
- **WHAT CAN YOU DO WITH THE TC70-1 ATV TRANCEIVER?** Show the shack, projects, computer program listings, home video tapes, repeat Space Shuttle audio and video if you have a TVRO, repeat SSTV or RTTY, Weather Radar, do public service events such as parades, marathons, races, CAP searches and rescues. . . .the list goes on. DX depends on antennas and terrain, typically 1 to 40 miles. We have video compensated RF linear amps for 20 ($119) or 50 ($189) watts pep for greater DX.
- **FEATURES:** Small 7x7x2.5". Push to Look (PTL) T/R switching. GaAsfet downconverter tunes whole 420-450 mHz band. Two switch selected video & audio inputs. RCA phone jacks and 10 pin color camera jack. Xmit video monitor output. Over 1 watt pep RF output on one or two (add $15) selected crystal controlled frequencies. 439.25, 434.0, or 426.25 mHz.

CALL OR WRITE FOR OUR CATALOG for more info or who is on in your area. We stock antennas, modules, and everything you need on ATV.

TERMS: Visa, MC, or cash only. UPS CODs by phone or mail. Checks must clear bank before shipment. Price includes UPS surface shipping in cont. USA, others add 3%. Transmitting equipment sold only to licensed Tech class or higher amateurs, verifiable in 1985 call book or copy of new license.

Build a Dynamic Duo

Add a speaker/mike and a 12-V adapter to your HT.

Dave Marling VE1VQ
Box 53A, RR1, Tusket
Yarmouth County, Nova Scotia
Canada B0W 3M0

My Yaesu FT-208R synthesized two-meter hand-held was purchased with the idea of making it something of a universal rig. While waiting for the mailman to arrive, I had visions of using it in the car to and from work, from hotels and rental cars on business trips, and even once in a while from my home.

Actual operation from a vehicle for an hour or so each day quickly indicated a couple of things that needed correcting to make mobile life easier; NiCd batteries don't last nearly as long as one might want, and RG-58 coax doesn't make the most flexible of microphone cords (especially on a cold winter morning!).

Speaker/Microphone

The external speaker/microphone (Photos A and B) was the first of the accessories to be built. I must admit to looking long and hard at the factory unit before seriously getting down to the task of construction. The deciding factor, however, was the offer of a free microphone connector by a fellow ham.

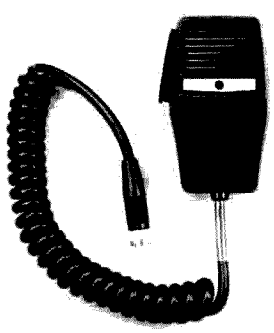

Photo A. Completed speaker/microphone. The mike cartridge is the dark circle in the white strip in the middle of the microphone.

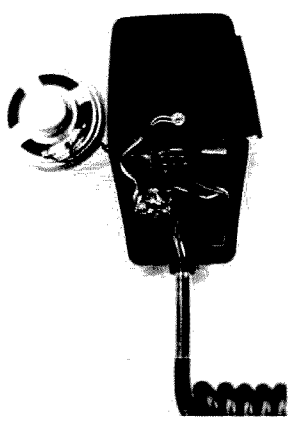

Photo B. Rear view of speaker/mike showing the microphone location. The grommet has been trimmed to allow the speaker to lie flat.

Digging through a box of discarded Citizens Band microphones produced an esthetically pleasing one with a defective cartridge. This same type of mike was used on the KDK FM-144-10SXR and quite a few 27-MHz rigs. A bit of measuring led me to the conclusion that a miniature speaker could, with some careful internal case trimming, produce a nice fit. The old cartridge was discarded and the case halves, screws, and coil cord were cleaned up with warm soapy water for a more presentable appearance.

The speaker was chosen to be close to the outside diameter of the plastic ring which held the original (discarded) cartridge (see Photo B). I used a Dremel-type hand tool with an edge-cutting disk to remove sufficient ring height to let the speaker fit with some looseness between the front and rear case pieces.

A hole of .203-inch (5.2-mm) diameter was drilled completely through the case front. Next, a drill of .234-inch diameter (5.9-mm) was used to partially enlarge the depth of the hole from the inside. Care should be taken not to let the bit pull itself all the way through. This enlarged hole was large enough to accept the new Yaesu mike element as a press fit.

If the drill wobbles and enlarges the hole, a drop of rubber cement, RTV, or other similar removable adhesive can be used to keep the mike in place. A small notch was cut in the case ring to allow the leads from the microphone to pass un-

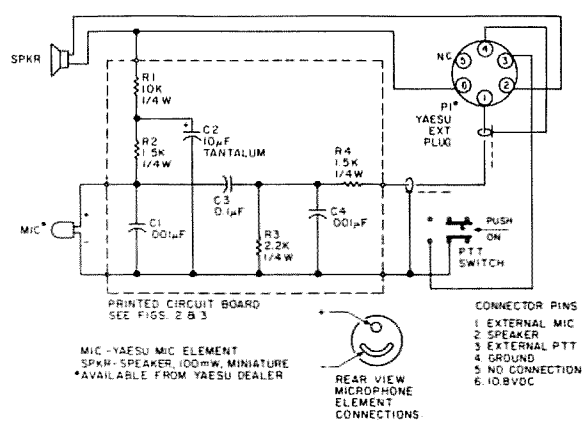

Fig. 1. Speaker/microphone.

der the speaker rim (via a small grommet).

The speaker leads were soldered to the correct coil-cord leads, and the junctions were covered with heat-shrink tubing. The leads from the mike cartridge as well as the necessary components were soldered directly to the copper areas on the small printed circuit board.

The board was cut and filed for a snug fit in the pocket provided in the front case half for the high/low power switch on the KDK. A scrap of carpet underlay glued to the rear case half keeps the speaker from rattling when the case halves are screwed together.

A small piece of aluminum strip with a .203-inch (5.2-mm) hole in the center is glued to the outside of the front, as shown in Photo A, to hide any drilling mistakes!

The parts are easily obtained. The speaker is a 1.75-inch (45-mm), 8-Ohm, 100-mW general replacement. The mike cartridge is a replacement element for the 207/208 series of hand-helds and is available along with the connector from your Yaesu dealer. Resistors are quarter-Watt, although eighth-Watt could be used. The capacitors (except for the 10 uF, which is tantalum because of the small size needed) are miniature ceramic.

Cigarette-Lighter Adapter

Now that I had an external microphone to make talking easier, I looked at the battery problem. Yaesu was kind enough to include the schematic of a solution in the FT-208R user's manual: a dc regulator circuit to power the unit from the cigarette-lighter receptacle.

My junk box didn't contain the same parts, so I made the necessary changes which are shown in Fig. 4. You will note that I left out the current-limiting resistor and plug that would allow me to charge the battery from the car, preferring instead a home-brew controlled-current charger kept in the shack.

A 15-volt, 1/2-Watt zener has been added to the input for two reasons. Any spikes over the zener voltage will be clipped before reaching the regulator section, and secondly, should the vehicle-battery voltage rise over the 15-volt point, the diode will short circuit and cause the fuse to blow, effectively letting you know that something is wrong and needs attention.

As can be seen from Photo C, the adapter circuit was built on a small piece of PC board 1.5 x 2 inches (38 x 51 mm). This board was mounted on standoffs (three 4-40 screws) in a plastic case that had previously housed a burnt-out ac-to-dc wall adapter.

No PC-board layout is given since the circuit is fairly easy to make by hand with a resist pen. Point-to-point wiring can be used just as well. The heat sink for the pass transistor (TIP42C) is made from a scrap of .062-inch (1.6-mm) aluminum.

Adjustment is simple. Insert the fused plug into a vehicle cigarette-lighter socket. With a VOM connected to monitor the voltage across the output plug, adjust the 1k-Ohm potentiometer for 10.8 volts.

My unit was tested for two hours on continuous one-Amp load. Output voltage dropped by less than 0.3 volts, and the heat sink was only comfortably warm to the touch.

Last Words

While the gadgets described were built for the Yaesu FT-208R, there is nothing to stop anyone from adapting them for many of the multitude of hand-helds out there in vacuum land. Changing the mike element, the connections, and the connector should suffice if your rig uses a similar electret cartridge. If yours takes a standard (non-electret) type, the PC board won't be necessary.

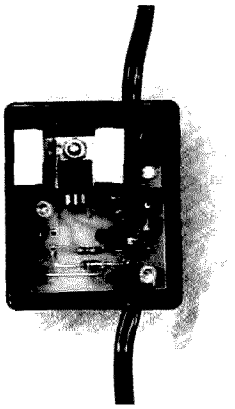

Photo C. Interior view of the dc regulator. The plastic case allowed me to use oversized heat sink for good heat dissipation.

As for the adapter, possibly only a simple adjustment of the potentiometer will be required. The adjustment range with the values shown is from 8.5 to 12.7 volts (with 13.8 volts input).

Synthesized two-meter hand-helds may not be the perfect rig—yet—but a few additional accessories can go a long way towards that goal. ■

Scanning the TR-2400

A simple mod for lazy hams—push the button and it scans!

My Kenwood TR-2400 handie-talkie has served me long and well. It is an especially nice companion at work, where I drive through the late-night hours. At these times the bands are inactive, and even scanning the ten memories I find my radio time quiet and disappointing. The TR-2400 can be scanned manually by keeping the scan-down button depressed. This can be tedious; it requires your constant attention. For this reason, I began looking longingly at the newer autoscan HTs.

The feature of band scanning would give me just what I wanted. The price of the new HT seemed reasonable, and my TR-2400 could be kept for my darling, almost-licensed wife. But stop and add up the total cost. The HT isn't what gets you—it's the price of the accessories. I might as well buy a full-size radio with all the other bells and whistles. The base charger, speaker mike, battery packs, etc., really boost the price!

I brought out the service manual, and after about a half-hour of tracing wires it appeared that by switching the scan button with a transistor, the TR-2400 could be scanned. All one would need for this project was a switching transistor (2N2222,

Photo by Joseph A. Cihy

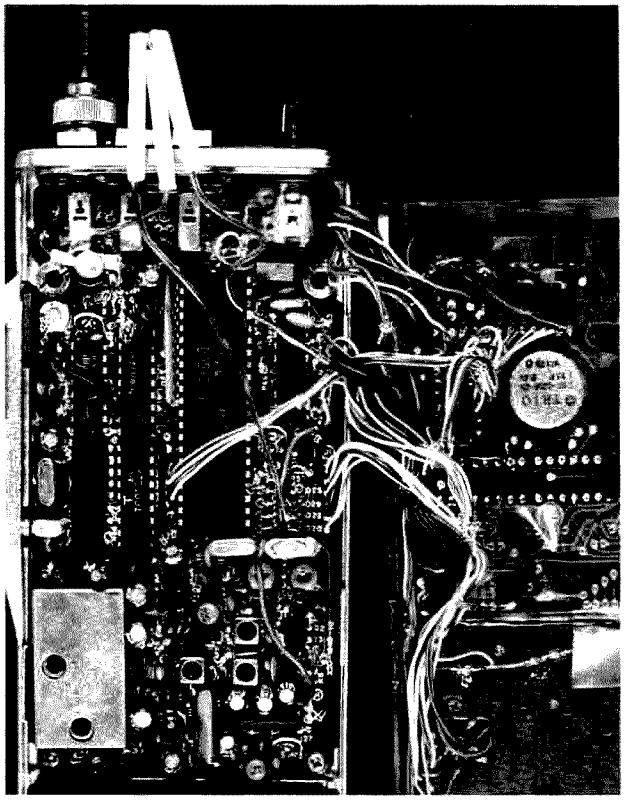

Photo A. Tape all of the leads to avoid a short circuit.

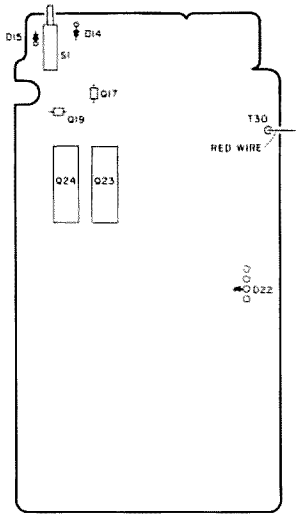

Fig. 1. The PLL board. S1 is the scan-busy switch which is to be modified. The bases of D14 and D15 must be hard-wired together. The collector of the scan transistor is spliced into the red wire at T30. The emitter is wired to the top of D22. The collector of Q17 is taken, through the switch and resistor, to the base of the scan transistor.

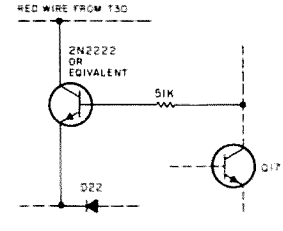

Fig. 2. The entire schematic.

or whatever), a resistor of about 50k, and some wire.

The preparation, however, is a little more complicated. If you have never worked on a synthesized, microprocessor-controlled HT before, read this carefully!

Preparation

1. The day you plan on working on the rig should be your day off.

2. The day before, do whatever it is you do to get all your frustrations out!

3. Reconcile all relations that were severed in the above step.

4. Get a good night's sleep. Don't start on the HT until after you have your coffee, read the paper, etc.

The Modification

This modification is for radios with serial numbers between 006XXXX and 010XXXX. I will describe the steps, and if you have another model you should be able to implement the change without too much trouble.

The front cover needs to be removed first. Remove the battery and take out the two screws in the battery compartment. Leave the two middle screws on the back cover in place. Take out the top two screws. The front cover can now be removed, *carefully*. There is a rat's nest of interconnecting wires, all of them easily broken. Pretend it's a bomb.

Remove the four screws holding the PLL board in place. Pull the board down toward the battery compartment. The board should now be free.

We are now going to work on the scan-down button. I chose this one (rather than the scan-up) because it is easily locatable. If your scanning radio locks on a channel you are not particularly fond of, you can reach over and touch the scan-down button again to bypass that channel. The radio will lower its frequency by 5 kHz each time. Once the squelch closes, the radio will begin scanning automatically.

The schematic showed that by connecting points Y4 and T30 I would have effectively pushed the scan-down button. Y4 can be picked up easily on top of diode D22. T30 is the connection point for the red wire, and I could not locate an easy way to pick up that point. Stripping some insulation back from the red wire provided that connection. Hard-wiring these wires gave me the scan-down for which I was looking.

Now I needed a scan voltage. I could say something brilliant about finding this, but to tell you the truth a VTVM and some poking around was all it took. Pin 36 on the microprocessor is the squelch-suppression input. This is controlled by Q17. The collector of that transistor gave me the low on signal, high on mute, that I needed.

The busy/open switch, a useless entity on my radio, was used to turn the scanner on and off. Take the switch off the board and bend the pins up. Attach two wires to the top two contacts. Remount the switch, being careful not to overheat the pads. Hard-wire the base of D14 to the base of D15 with a short piece of wire. This wire takes the place of the switch.

Take one of the wires from the switch and bend a very small hook in its end. With the radio off and the battery removed, hook this wire onto the collector pin of Q17. This is the *center* pin. Solder the wire very quickly with a low-wattage iron. Don't burn out the transistor.

Solder a piece of wire onto the red wire and another from the top of D22. Put a piece of heat-shrink tubing or spaghetti over these wires and hook them up to the transistor. The wire from the diode is attached to the collector and the wire from T30 is soldered to the emitter. Slide the spaghetti over the connections.

So far, so good. I had to experiment with the resistor in series with the base lead. I finally determined that 51k was the proper value and soldered one to the base lead. The second wire from the switch is then attached to the resistor. Wrap the transistor in tape and place it against Q23 and Q24. If you have been extremely careful, you're ready to button it up.

Very carefully see if you have broken any of the many interconnecting wires. If you have, I strongly suggest you take a nice long break. Have a cup of coffee, watch a program on TV, visit Hawaii. If any of the wires are broken, others will probably be in the way when you attempt to reattach the cover. Do your best.

Be especially careful about the power-supply wires and L101, the choke coming off the battery lead. It is very easy to smoke the radio by pinching one of these wires. I have done this twice now.

Operation

Operation of the scanner is easy. Push the button and it scans. It will stop on a channel if a signal is present. There is no delay; the radio will resume scanning when the signal is dropped.

I have found that the scanner will stop on the center frequency about ninety percent of the time. It rarely stops after the signal has been passed.

With a new Radio Shack transistor (276-2009) at 79 cents and a new 51k resistor at two for 19 cents, the total price comes to 98 cents. Charge yourself $30.00 per hour for labor (the going rate!). Now, take your profit and go out and buy that computer you have wanted. ■

"When You Buy, Say 73"

PACKET RADIO GOES PORTABLE

GLB ELECTRONICS
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement:
9 to 15 Volts DC @ 25 mA typical

Dimensions:
4.6 X 5.90 X 1.0 inches

Total Weight:
12 ozs.

The RIT Stuff

Clarify your FT-101E's reception with this five-component modification.

The DX bulletin indicated that the newest DXpedition was expected on 20-meter CW about 1300Z. Since working their island would put me one step closer to DXCC, I made a mental note of the frequency and time. When the twenty-four-hour clock turned over to 1300Z, my FT-101E was set and ready to join the pileup. A little tuning found them at 14.028, but the hordes of calling stations were up around 14.035.

Well, a spread of 7 kHz fell smartly beyond the ±5 kHz of the RIT (clarifier) circuitry in my transceiver. After several earlier attempts to move the vfo back and forth to catch a station working split frequency, I had learned it was pretty frustrating. Foiled again! Of course, similar tales of woe can be told about working European stations on 40 SSB, especially during contests. The Europeans cannot use sideband above 7100 kHz, while the American phone subband starts 50 kHz higher. That's really stretching an RIT control.

After a few of these situations, it was clear that an external vfo could be very helpful for the kinds of operating that I was doing. Earlier, though, Yaesu had put the FT-101E model out of print, so to speak. This apparently was because of projected problems obtaining the sweep tubes to support their production and replacement requirements. So, I started checking out the used equipment

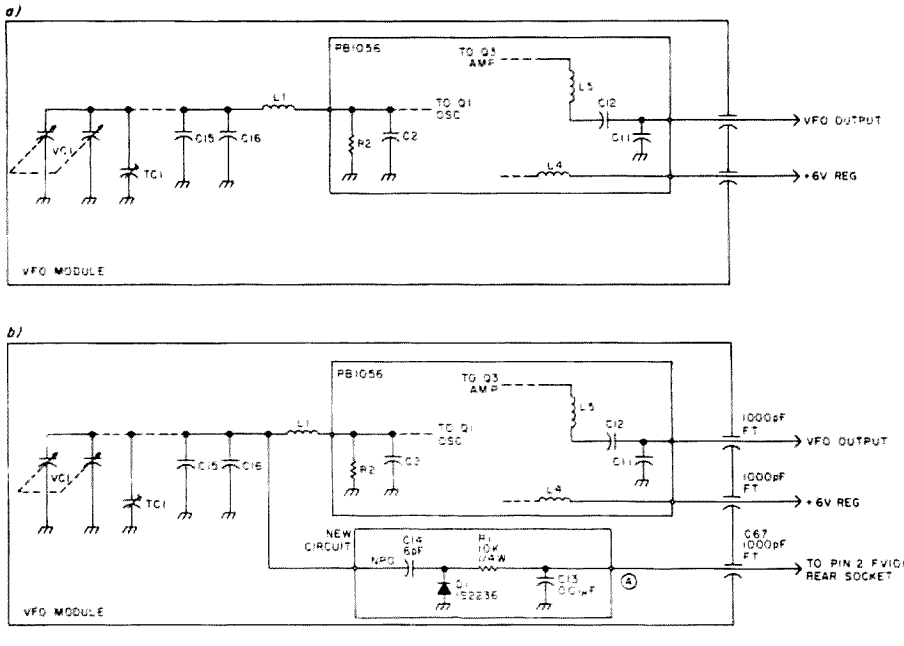

Fig. 1. Partial schematic drawings of FV-101 vfo before (a) and after (b) modification to include RIT circuitry. Components on the added board are indicated in (b).

market. I realized quickly that when an FV-101B external vfo did turn up, it inevitably was bought very quickly. In time, though, I managed to find an older version (FV-101) that was intended for the earlier FT-101s. The popularity of this accessory was indicated by the used price being above its original value.

After first checking the unit out, it appeared to work as it should. However, when I set the vfo selector switch to external transceive, I noticed that the RIT control on the FT-101's front panel didn't have any effect. Nor did the RIT circuitry work when the remote vfo was used to control only the receiving frequency. This seemed curious since it certainly is useful to have full RIT capability for both vfos.

Determined to correct the problem, I pulled out the two owner's manuals and studied the schematics for each vfo. This showed that nothing was wrong with my "previously-owned" FV-101. Yaesu simply had not put the RIT circuitry in it. If you examine Fig. 1, you will see that only five components need to be added to the FV-101. The remaining circuitry is contained within the transceiver. None of the components is difficult to get. For your reference, several suppliers are listed in the box. Undoubtedly, there are others as well. The total cost of the components should be around five dollars, assuming that your junk box is empty.

So this became the latest home-brew construction project for me. It seems that the way many of these work out is that what electrically looks like child's play often turns out to be rather involved mechanically. This principally is because the compactness of our modern rigs leaves little room for fingers and tools. Relax, though; much to Murphy's amazement, this modification is a breeze!

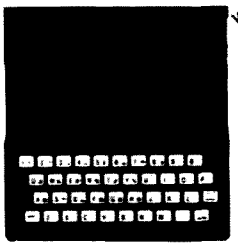
What is necessary, of course, is to add the varactor diode (D1) and its associated circuitry inside the remote vfo and connect it to the transceiver. The circuitry itself is not difficult to understand conceptually. A low dc voltage is applied at point A in Fig. 1 (b) by means of a connection to the RIT control on the FT-101E/EE/EX front panel. This voltage is applied to the varactor diode through a current-limiting resistor and this is varied by the setting of the RIT potentiometer on the transceiver's front panel.

A primary characteristic of varactor diodes is that the capacitance across the P-N depletion zone changes with the applied voltage. This capacitance is non-linear and is proportional to the square or cube root of the voltage. The actual capacitance range obtained in this manner is in the order of a few pF depending upon the diode's reverse breakdown voltage and its forward conduction. Those who want to experiment might try using a rectifier diode. If you are interested in reading further about these diodes, a more comprehensive discussion can be found in References 1 and 2. The varactor capacitance, acting together with temperature-compensated series capacitor C14, provides the incremental frequency change as the RIT pot is varied. A relay inside the transceiver is used to disable this circuitry during transmit.

The point that the RIT circuit functions at dc is important because this means that component placement, stray lead capacitance, etc., will not affect performance as they do in many rf circuits. The components that need to be added to the FV-101 (except for the feedthrough, C67) can be mounted on either perfboard or a small PC board. I prefer the latter since it generally allows a neater assembly and has another advantage that we'll get to in a minute.

Parts Suppliers

C13, R1—Radio Shack; Circuit Specialists, Box 3047, Scottsdale AZ 85257.
C67—Semiconductor Surplus, 2822 N. 32nd Street, Unit 1, Phoenix AZ 85018.
C14—Circuit Specialists.
D1—Electronic distributors, e.g., Hatry's, Ledyard Street, Hartford CT. RCA SK3126 & Workman WEP200 are equivalent to the 1S2236. Distributors will also carry many/all of the above components.



The RIT circuitry board is installed inside the vfo module. I found that mounting this board to the removable bottom cover of the vfo module was the most convenient. Access to this cover is gained by removing the cabinet and turning the unit upside down. I used a couple of machine screws and small (¼-inch) metal standoffs for the mounting hardware. The board was positioned near the rear of the cover plate (on the inside). At this point, the extra advantage of the PC board approach becomes apparent. This is simply that the ground connection between the vfo and RIT circuits is automatically established by the PC board's ground foil. Be sure to make this ground connection with a separate wire if you elect to use an unclad perfboard for your work.

A length of hookup wire connects from C14 on the board to the side of L1 that is connected to VC1, etc. Another wire is run from point A to a feedthrough capacitor mounted in the side of the vfo module adjacent to the two existing feedthroughs. In my FV-101, there already was a convenient hole at that point. You may find that it is easier and faster to use a screw-in feedthrough rather than the solder type. Finally, another length of hookup wire connects this new feedthrough to pin 2 on the FV-101 rear socket which was originally unused. This completes the FV-101 circuitry modification and all that was involved was a few components and some wire. Life would surely be easier if all equipment modifications were so straightforward.

The next step involves connecting the remote vfo to the RIT circuitry in the transceiver. Fortunately, this is equally simple. Remove the screw-on cover from both plugs on the remote vfo cable and install another piece of wire inside the cable jacket. This will be easy to do if you use a coathanger or such to pull the wire through the vinyl jacket. Then solder the new wire to pin 2 of each plug and put the plug covers back on. This provides a neat cable assembly without any loose wires cluttering your desktop.

Now remove the screws and two small nuts that attach the bottom cover to the transceiver. Solder a wire from pin 2 of the FT-101 external vfo socket to the RIT (clarifier) feedthrough capacitor located on the transceiver vfo module. Be careful, as there are three feedthroughs here. A VOM can be used to identify the correct one since it is the only feedthrough connected directly to the wiper arm (center contact) of the RIT potentiometer. The placement of this wire between the jack and vfo module is not critical.

Prior to putting the FV-101 back in its cabinet, it is necessary to take a moment to align its vfo to the main vfo in the FT-101. The extra added capacitance in the

circuitry will change the FV-101 frequency somewhat and the actual frequency will not agree with the dial calibration markings. All that is required is a screwdriver adjustment. Initially, both vfos should be checked against the calibrator reference signal in the FT-101.

With the RIT switch off, inject a signal from an rf generator into the radio's antenna connector and zero beat it with the transceiver vfo. Note the frequency on the transceiver's dial and tune the external vfo to the same frequency. The vfo selector switch should be turned to either the External or RX Ext position so that the FV-101 is controlling the receive frequency. Now adjust TC1 with an alignment screwdriver to zero beat the rf generator's signal. There are two alignment capacitors (TC1, TC2) and an access hole for each is provided in the top cover of the FV-101. TC1 is located on the left when viewing down from the front panel of the unit. If a signal generator isn't available, a steady on-the-air carrier signal will suffice.

Well, that completes the entire modification, and the transceiver bottom cover and the FV-101 cabinet can now be replaced. You should find that the RIT control works regardless of which vfo is being used to select the receive frequency. If this is not the case, go back and check your wiring (remember Murphy). Again, be sure that the new RIT circuitry has a common ground with the FV-101 itself. I hope that you will find this modification to be as useful as I have. Good luck in the pileups! ■

Rebirth of the Eico 221

Turn this flea-market regular into a super-sensitive voltmeter. Then count the money you saved.

Dick Dreher W5VTJ
12645 E. 31st Court
Tulsa OK 74145

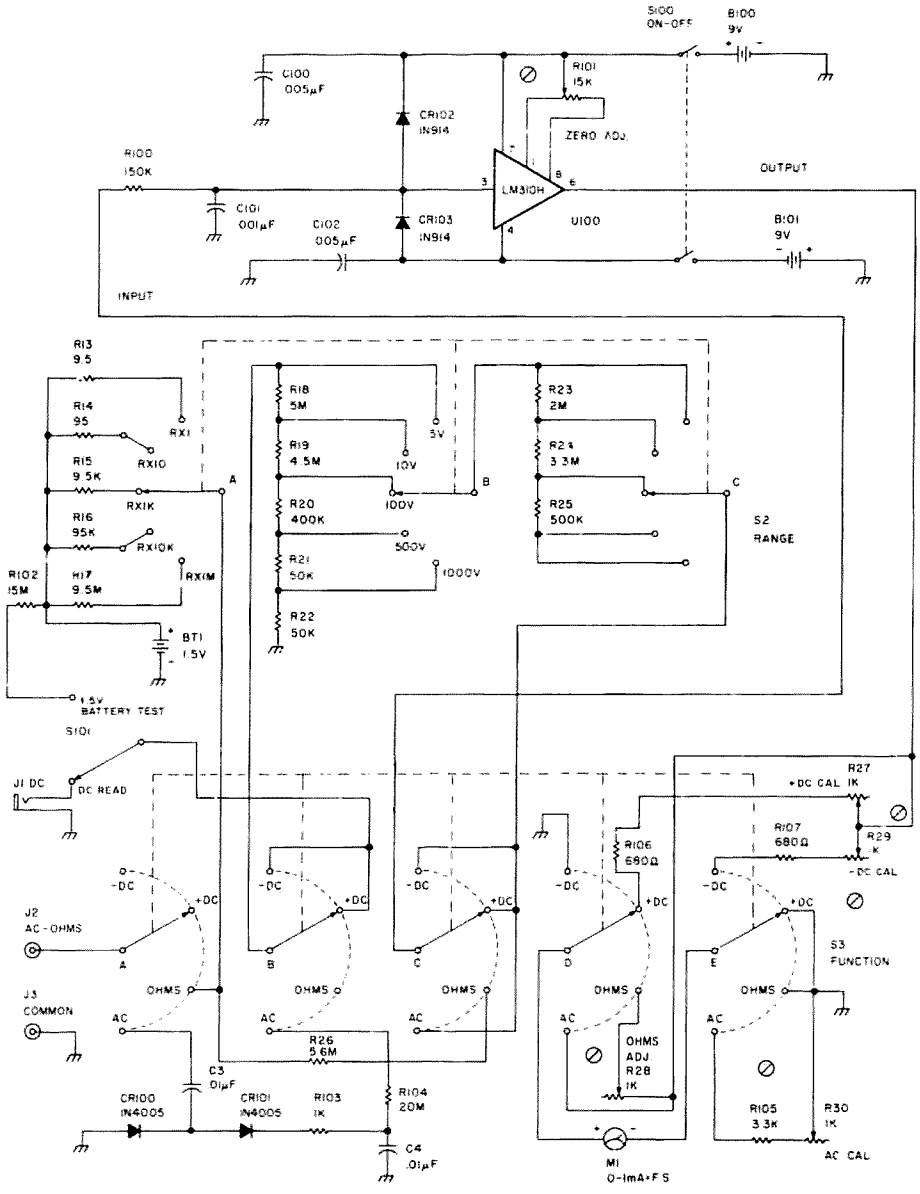

Fig. 1. Meter after conversion.

If you have scanned the meter pages of electronics catalogs lately looking for a meter with high sensitivity, you quickly become "sensitive" to high prices. Most ham auctions and sales usually will yield an Eico 221 for about five bucks. Mine cost low, as the transformer was scorched.

This conversion permits very sensitive measurements at 10 megohms per volt in solid-state circuitry and applications where ac power for a VTVM is not readily available (such as mobile gear, etc.). Though unable to measure current as some VOMAs and DVMs, its cost and sensitivity offset this shortcoming.

Mike Kaufman K6VCI did a good job on his article in *Ham Radio Magazine*, December, 1974 ("How to Convert Your VTVM to an IC Voltmeter"). He shows you how to convert the Heath IM-11. In comparing his arti-

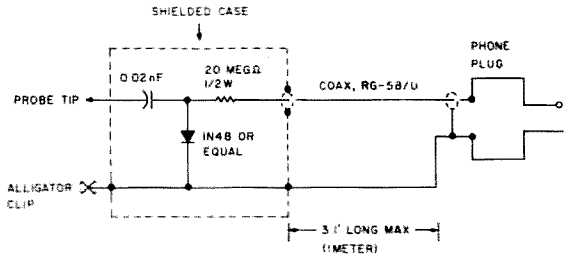

Fig. 2. Rf probe circuit.

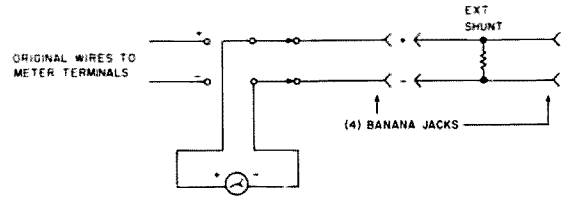

Fig. 3. Milliammeter circuit.

cle with converting the Eico 221, I noticed some differences.

This article will show you how to enjoy the original features of the Eico 221, yet have a meter that is totally battery-operated. Conversion is relatively simple for the average builder-hobbyist.

Fig. 1 shows the meter after conversion. It would be helpful to have the original construction manual when doing the modifications. I didn't enclose photos of the conversion as the text is fairly descriptive.

Note the parts in Fig. 1 designated "100" as "U100". These are new parts you add. Most are available from Radio Shack, Poly Paks, etc. See the parts list for descriptions.

This conversion is begun by removing unnecessary components. See your Eico 221 book for parts locations if they are not clear. Parts with an asterisk (*) are on the Function switch, S3. Remove (and put in your junk box): The ac line cord, On-Off switch (S1), power transformer (T1), pilot lamp (B1) and holder, all tubes (V1-V3), resistors R1 (10k, 2 W), R2 (33k, 2 W), R3 (20k), R4 and R6 (1.5 megohms), R7 (5 megohms), R8* (1 megohm), R9 (5 megohms), R10 and R11* (1k), capacitors C1 and C5* (0.002 μF), C2 (filter), and C4* (0.01 μF). Save C4* for conversion. Also remove potentiometers R5 (2 megohms, Ac Zero Adjust) and R12 (2k, Zero Adjust).

Install R101 (15k) in the front panel hole where R12 was. If you strip the chassis clean, except for adjustment pots and their wiring, you removed all of the above parts. Do not disturb the wires on or to Function or Range switches at this time. Cut any of the wires from these switches at the chassis end and tag them as to original connections. If you use the tube sockets for the new circuit, leave them as is. Enlarge the hole in the panel where the pilot lamp holder was to 1/2-inch (12.7mm) diameter and

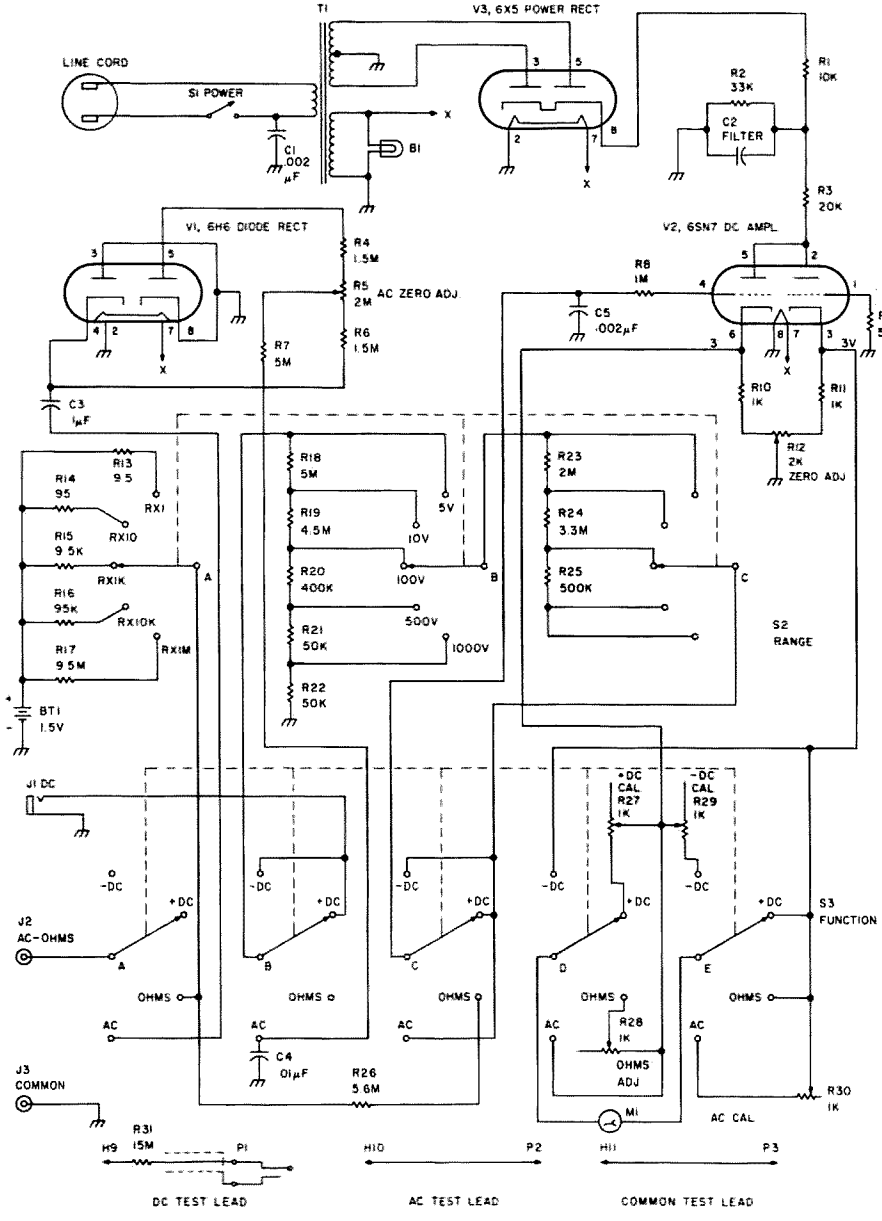

Fig. 4. Meter before conversion.

Parts List	
B100, B101	9.0-volt transistor battery with connectors (battery holders optional)
C100, C102	0.005-μF, 50-volt mica
C101	0.001-μF,50-volt mica
CR100, CR101	1N4005 or equivalent 600-plv,1-Amp diode
R100	150k, 1/4 W, 10%
R101	Pot. 15k, 1/2 Watt, panel-mount type
R102	15 meg, 1/4 Watt, 10%
R103	1k, 1/4 Watt, 10% (can use old R10 or R11)
R104	20 meg, 1/4 Watt, 10% or (2) 10 meg, 1/4 Watt, 10% in series
R105	3.3k, 1/4 Watt, 10%
R106, 107	680 Ohms, 1/4 Watt, 10%
S100	toggle switch, DPST
S101	toggle switch, SPDT
U100	IC, National Semiconductor LM-310H voltage follower

mount switch S101 (1.5-V Battery Test switch). This switch does two things—it fills a vacant hole, but more important, it allows you to test the ohmmeter 1.5-volt battery. Break the wire from the Function switch to J1 (dc jack) and wire in this switch. R102, the 15-megohm resistor, can be mounted on Range switch S2.

Mount switch S100 in the hole where the original On-Off switch (S1) was located. Batteries B100 and B101 may be mounted in special clips available for them or mounted to the chassis with cable ties or strapping tape. Use connectors that mate them or make your own from discarded 9.0-volt batteries. Batteries need replacing periodically, so soldering them is not advisable. U100 can be soldered into one of the existing tube sockets or push out one of the transformer grommets and insert a round nylon 8-pin IC socket in the hole and wire to the socket.

All remaining parts may be wired to the two remaining sockets or mount to some 3-lug solder strips mounted on the chassis. A perforated Vectorboard® could also be used. This part of the conversion is mostly left up to the hobbyist's ingenuity. C4 was on the Function switch and is relocated on the chassis. Use insulated hookup wire for all wiring. Lead dress is not critical, but capacitors C100, C101, and C102 should be wired close to U100. R106 and R107 can be mounted on Function switch S3. Break the wiring to R27 and R29 and insert them in series. R105 is inserted from R30 to S3, deck E. Break wiring to R30 and put in series. Be sure to ground the wire which went to pin 3 on the V2 (6SN7) socket and decks D and E on the Function switch.

Theory of Operation

Capacitors C100 and C102 bypass the battery power supply. Diodes CR102 and CR103 prevent an overvoltage condition if you are probing a large voltage while the meter is switched to a low-voltage range. They limit voltage on U100, pin 3 to ±9.0 volts dc. Resistor R100 limits current into CR102 and CR103 and forms part of the protective circuitry. Capacitor C101 keeps any ac out of U100's input. Its value is not critical except increasing its value will increase the measuring time. Potentiometer R101 is the new Zero Adjust pot.

Diodes CR100 and CR101 replace the original 6H6 diode circuit. They should be at least 600-piv, 1-Amp types. CR100 clips the negative half of the cycle to ground after coupling through capacitor C3. CR101, R104, and R103 "steer" the positive half of the cycle to the Function switch and Range switch circuit as dc input does. C4 bypasses any stray ac to ground.

Calibration

With unit power off and the S101 1.5-V Battery Test switch set to Dc Read, adjust the mechanical zero screw on the meter until the needle points to zero. Turn the S100 meter power switch on and adjust the Zero Adjust control (R101) until little or no change occurs when the Function switch goes from +dc to −dc with no probe input. Probe a known dc voltage and adjust the Dc Cal control for the correct meter reading. Position the 1.5-V Battery Test switch to read the ohmmeter battery on the 5-V scale. You should read about 1.5 volts on a new battery. Position it back to Dc Read. Next, switch the Function switch to the Ohms position and set the Ohms Adjust control on the front panel so the meter reads infinity resistance (on left side of scale) with the resistance probe open-circuited (not shorted to the ground probe). Touching these probes together will bring the needle to read zero Ohms on the right side of the meter scale.

Never leave the meter in the Ohms position or S101 in the 1.5-V Battery Test position as the latter disables the meter from reading dc and the first is normal procedure. The battery could drain over a few months. Finally, put the Function switch in the Ac position and adjust the Ac Cal pot until a known ac voltage reads correctly on the meter. Caution: Do not use the ac line to calibrate this meter as one side of the line will always be on the panel and chassis and a serious shock could result. A suggested method is to use a 6.3-V-ac transformer and calibrate the meter on the 10-V-ac range, comparing the reading with a known good meter.

Always turn this meter off when not using it, as the LM-310H draws about 4 mA and will consume the batteries in a period of time. An LED Power On indicator would consume 20 mA from the power supply, so it was not part of this conversion.

Another useful application in ham radio for this conversion is to use an rf probe into the ac input and measure relative power output and antenna field strength. A short piece of wire or a clip lead on the end of an rf probe will pick up enough rf energy to give a good reading. Eico had a model PRF-25 probe available for this VTVM, or a simple probe may be made with a 1N48 diode, a 0.02-μF, 600-V capacitor, and a 20-megohm, 1/2-Watt resistor in a shielded tube or enclosure. See Fig. 2.

If you still need a milliammeter, the basic movement here is 0-1 mA dc full scale. Mount a DPDT switch on the front panel and wire the meter terminals to the common contacts. Wire two banana jacks to the normally-closed contacts and connect the two original meter wires to the normally-open contacts (see Fig. 3). The banana jacks could be mounted on the back of the cabinet. Of course, the main on-off switch stays off to use the 1-mA function. By experimenting with resistor shunts across the banana jacks, this 1-mA range can be extended to several Amps. Start with about 90 Ohms and go as low as 0.1 Ohms and compare the reading with another milliammeter in series with this meter between a dc power source and a load. With the proper shunt, this meter should track the known meter. ■

Super-Selectable Bandpass Filters

PAØSE uses extraordinary methods to craft the ultimate i-f filter.

It is very convenient when the bandwidth of a ham receiver can be adapted for different circumstances. That is to say, to the kind of signal to be received—telephony, telegraphy, RTTY, FAX, etc., and to the interference caused by other stations which, especially on the HF bands, is practically unavoidable.

Commercial receivers and transceivers sometimes offer the possibility of selectable bandwidth. That is realized by providing several i-f filters with different passbands that can be selected by a switch. In order to keep the initial price low, often a single filter is built in as standard and the extra filters can be ordered separately for a considerable amount of money. The price of i-f filters is the reason that even the "deluxe" transceivers and receivers usually provide only limited choice of bandwidth.

For the home-brewer who constructs a modern receiver with a high intermediate frequency, say over 4 MHz, the possibilities are no different than those for the professional designer. He, too, must buy a separate, expensive bandpass filter for every value of bandwidth desired. It is in principle possible for the amateur to make his own crystal filters, but this remains a tricky business and it is difficult, if not impossible, to realize a predictable bandwidth.

But there is a different way. We can construct a multi-resonator bandpass filter using coils and capacitors on a relatively low i-f—50 kHz for instance. It is not difficult to make the passband width of such a filter switchable to as many different values as we desire. Such a low i-f dictates the use of double- or triple-frequency conversion in a superheterodyne receiver for the HF bands in order to retain a reasonable attenuation of image responses. That may seem a bit outdated, but when the receiver is carefully designed, this should not pose insurmountable problems. Even in some famous commercial receivers, like the Drake, this system is used.

For my own ham-shack receiver, which I constructed some seventeen years ago, I followed this approach using a final intermediate frequency of 50 kHz. This receiver still copes fully with conditions on the amateur bands of today. The original filter was made with seven capacitively-coupled resonant circuits, and the passband was 2.7 kHz wide.

That was OK for single sideband, but for other modes, like CW and teleprinting with the "hell" system (see Hans Evers PAØCX (DJØSA), "The Hellschreiber, A Rediscovery," *Ham Radio*, December, 1979), I began to feel the need for some smaller bandwidths. That was the reason I replaced the seven-circuit bandpass filter with fixed passband by an eight-circuit one having selectable bandwidth. Together with passband shift, this gives me the capability to match the receiver bandwidth to the actual receiving conditions in an optimum way. This filter is the subject of this article.

It may be of interest that I use a similar filter in my homemade single-sideband transmitter for the bands 10 to 160 meters. That filter employs six tuned circuits on about 20 kHz. Sideband and

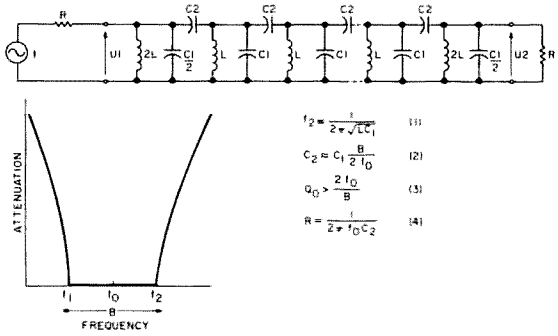

Fig. 1. Basic circuit of a capacitively-coupled bandpass filter.

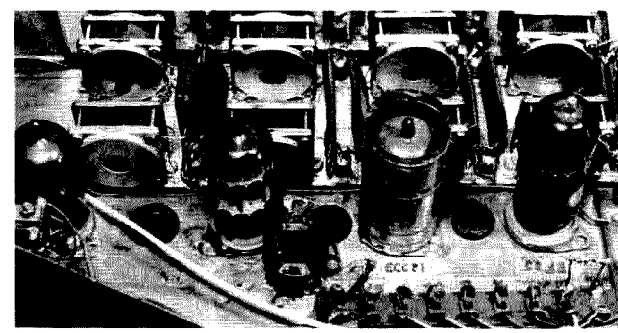

Photo A. The filter mounted in PAØSE's homemade hamband receiver.

carrier suppression are extremely good and stable and the quality of the SSB signal can successfully compete with any modern conception.

Principle and Design—A Switchable I-f Filter

The principle of an LC filter with capacitive top coupling is indicated in Fig. 1. At the left is shown how the passband is defined as the frequency difference between the upper limit, f_2, and the lower limit, f_1. f_0 is the so-called central frequency. The band between f_1 and f_2 is called the passband with width B.

Modern filter theory permits one to design a bandpass filter using this configuration with predictably exact characteristics. That is to say, we can prescribe f_1 and f_2 and also the slope of the transitions between the passband and the stopbands below f_1 and above f_2.

The values for coils and capacitors can be found by computation and also in recipe books for filters. But the awkward thing about it is that all coils and capacitors usually end up with different and odd values for self-inductance and capacitance—37.21 pF and 9.82 mH or so, for instance. When the passband width should be switchable, the situation becomes even more embarrassing because the values of all coils and capacitors have to be changed.

It is easier, therefore, for the amateur constructor to design the filter according to the classical "image-parameter" method. The disadvantage of this approach is that the filter characteristics cannot be predicted exactly when using non-ideal components and filter terminations. Also, the transitions between pass- and stopbands will be less steep than for an optimal filter designed using modern filter theory. But the pleasant aspect of an image-parameter filter is that all filter sections except the first and the last are similar.

Fig. 1 is applicable, too, for a filter designed by classical filter theory. All coils have the same self-inductance value, L, except the first and the last coil; these have 2L. Also, all parallel capacitors are similar with value C_1, except again for the ones in the end section which are of value $C_1/2$. Coupling capacitors C_2 are all similar, and they determine the width of the passband.

Let us now take a look at the formulas in Fig. 1. The first shows that upper limit f_2 of the passband is determined by the resonant frequency of the parallel tuned circuits on their own. That is, L in parallel with C_1 for the intermediate sections and 2L in parallel with $C_1/2$ for the end sections.

At lower passband limit f_2 each coil resonates with the total capacitance connected to it: for the intermediate circuits, L in parallel with $C_1 + 2C_2$, and for the first and last section, 2L in parallel with $(C_1/2) + C_2$.

With some approximations, the second formula can be derived from this, allowing us to compute C_2 for a desired bandwidth, B. As already stated, this is an approximation: The actual bandwidth obtained can deviate considerably from the computed one. It is useful as a starting point, however, and the actual value for C_2 necessary for a certain bandwidth, B, can be found quickly enough by experiment.

The third formula is an important one. It indicates the minimum circuit Q_0 required in order to obtain a certain bandwidth. The narrower the passband desired, the higher Q_0 has to be. This shows why we cannot construct the filter for a high intermediate frequency. Say that we want B to be 2.5 kHz and $f_0 = 9$ MHz. The minimum circuit quality, Q_0, in this case has to be $(2 \times 9000)/2.5 = 7200$. No coil will ever be that good, but quartz-crystal resonators are, and these indeed are used in such i-f filters.

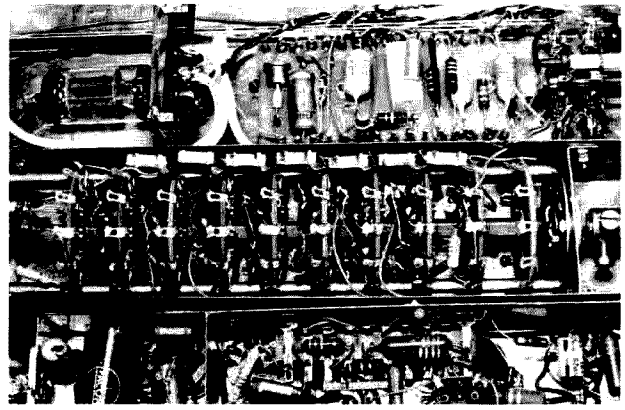

Photo B. View of the filter from the bottom of the receiver. Coupling capacitors and loading resistors are mounted directly on the switch decks.

So we should start by making the best coils we can at the chosen intermediate frequency, f_0. (The Q of the capacitors is usually so much higher than that of the coils that Q_0 of the circuit is set by Q_0 of the coils alone.) For the frequencies concerned, we have to make use of ferrite pot cores and Litz wire. The ferrite should be suitable for the frequency we want to use. The bigger the pot core, the higher Q_0 becomes. Also, we should try to fill the space inside the pot core completely with the winding. How the Q of the circuit can be measured will be shown later.

For my own filter, with f_0 about 50 kHz, I used 1-inch ferrite pot cores of Philips manufacture. It is a now-obsolete type, designated as K300063. The coil has a slug for fine-tuning. No doubt suitable ferrite pot cores of other manufacture can be obtained outside my country.

I tried several types of Litz wire from my junk box, even home-brew, made by twisting two insulated 0.25-mm (30 AWG) wires. But the highest Q was obtained by using 28 × 0.05 Litz wire (28 strands of 0.05-mm diameter) that was kindly provided by PA0LQ from his personal store. Q_0 varies a bit from coil to coil but is of the order of about 370.

We now know the minimum passband width we can obtain, because from the third formula comes $B_{min} = 2f_0/Q_0$, and $2 \times 50000/370 = 270$ Hz. We can get even narrower passbands, but the insertion loss in the passband then increases quickly. The tuned circuits become undercoupled—something you may remember from the theory of double-tuned circuits.

Finally we have the fourth formula. That one states that the end sections of the filter shouuld be loaded by a resistor the value of which is equal to the reactance of the coupling capacitors, C_2. This is not very critical. We may use a somewhat greater value for R than the formula prescribes, but if we go too high, ripples in the passband appear. We should also realize that the loading resistor, R, assumes theoretical, that is, lossless, coils. In the real world coils do have losses, and the losses in the first and the final coil already provide some of the loading. This implies that at the narrowest bandwidth the external loading resistors can be omitted, as all loading is already provided by the "loss

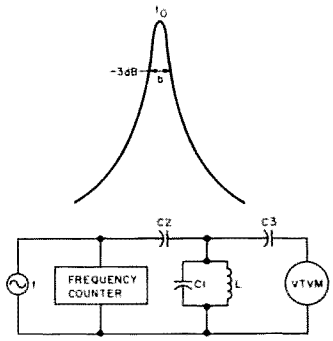

Fig. 2. How unloaded quality factor Q_0 is measured.

resistance" of the coils themselves.

Making the Filter

How do we make the actual filter we would like to possess? That is largely dictated by what your junk box provides in the way of capacitors of equal values. I assume you already possess or can obtain suitable ferrite pot cores. When we start by fixing C_1, then L is set as well, according to formula one. We now try to obtain the correct L with wire that fills the coil form as much as possible. (Note that the end coils have double the self-inductance!) If the choice of Litz wire is limited, we can also start by making the coils, filling the coil forms completely. The self-inductance, L, is then measured, and from this follows C_1.

Capacitors C_1 should be of good quality, mica or polystyrene. A small tolerance of capacitance value is nice to have but is not a must. We have to tailor the number of turns for each individual coil, anyway. Differences of up to 10% between the individual coils and capacitors do no harm as long as each parallel circuit can be tuned exactly to f_0.

I had a small batch of 2.5-nF mica capacitors for the intermediate sections. For the end sections, the capacitors should therefore be 2.5/2 or 1.25 nF, but those were not available. The junk box did provide capacitors of 1.35 nF, however, so these were used. The self-inductance of coils 1 and 8 had to be corrected for this, of course. The coils for intermediate sections 2 through 7 worked out at a self-inductance of 3.74 mH. That is a value I calculated after completion of the filter because, as stated already, the coils are individually tailored to the capacitors they are used with.

We start by putting in more turns than are necessary (according to the formula provided by the maker of the pot cores for obtaining a certain value of self-inductance). The coil is now temporarily assembled without the tuning slug. We now rig up the circuit of Fig. 2. C_1 is the capacitor that will be used with the coil under construction. C_2 and C_3 are as small as possible consistent with a reliable indication on the VTVM (a scope can also be used).

We now tune for resonance, as indicated by a maximum of the voltage over the circuit. This is very sharp! The frequency of resonance will usually be lower than f_2 as defined in Fig. 1. We now remove one or two turns of the coil and measure again. (That sounds worse than it is: The wire removed is simply left in the circuit; it has negligible influence on the frequency of resonance.) During the measurement, I simply press the two halves of the pot core together by hand.

We go on taking off turns until the resonance frequency is just slightly higher, say 2%, than f_2. We now can finally assemble the coil and insert the slug. If all is well we can now tune neatly around f_2.

It all sounds a bit complicated, but is the only method that guarantees tuning the circuits properly to the correct frequency. Only when you are lucky enough to have very small tolerance capacitors available (1% or better) can you wind all coils with the same number of turns, as calculated for your particular pots to reach the required self-inductance. The reason is that the slug permits only a small variation of the coil's self-inductance—some 2% or so.

In this way we proceed for all the tuned circuits, eight in my case. When the tuned circuits are ready, we can mount them on some suitable support. How you do this is not so important. But try to do it in such a way that input and output of the filter are well separated; otherwise some signal may bypass the filter in the stopbands. I used a kind of channel made of tin-plate—as can be seen in the photographs. The coils and the parallel capacitors are mounted on top; the switch and the coupling capacitors are inside the channel.

The complete circuit diagram of the filter is shown in Fig. 3. The number of different passband widths that you put in is up to you. It will probably be determined by the kind of switch you have available and the number of equal-valued capacitors in your junk box. I had a 12-position switch of which 10 positions are used.

As you can see in Fig. 3, there is a small capacitor, 3.3 pF in my filter, always in circuit. This was provided for alignment purposes. It is convenient when all circuits can simply be tuned to maximum on a test signal.

We can find a suitable value for the small coupling capacitor as follows. From the measured Q_0 of the coils, find the minimum passband width possible using the third formula. Entering this bandwidth, B, into the second formula then gives you the corresponding C_2. If you now take half of this value for the capacitor that is always in circuit, you will be OK. When the small coupling capacitors have been put in, we can start aligning the filter.

We need some indicator, like a VTVM or a scope, and we couple it lightly to the last circuit, number 8 in my case. Coupling can be done via a small capacitor. We also need some generator that is tuned to upper frequency limit f_2 of the filter passband. The generator is connected in parallel with circuit 7. It does not matter if this circuit is heavily damped by the generator. We now tune circuit 8 for maximum voltage.

Next, the generator is moved to circuit 6 and number 7 is tuned for maximum voltage. Then the generator is moved on to circuit 5 and circuit 6 is tuned for maximum voltage, and so on. If the signal on the last circuit becomes too weak for a reliable indication, we move the indicator to number 7 or 6. So we finally come to circuit 1.

The generator is now lightly coupled to 1 via a small capacitor in order not to detune it under the influence of the generator. When circuit 1 is also peaked, alignment is completed for circuits 2 to 7. We can fix the slugs with wax to make them stay put. Circuits 1 and 8 will get a final touch-up once the filter is mounted in the receiver to compensate for the capacitance of the stages preceding and following the filter.

Now you can start putting in the coupling capacitors for the switch positions you are going to use. It is simply a matter of soldering them

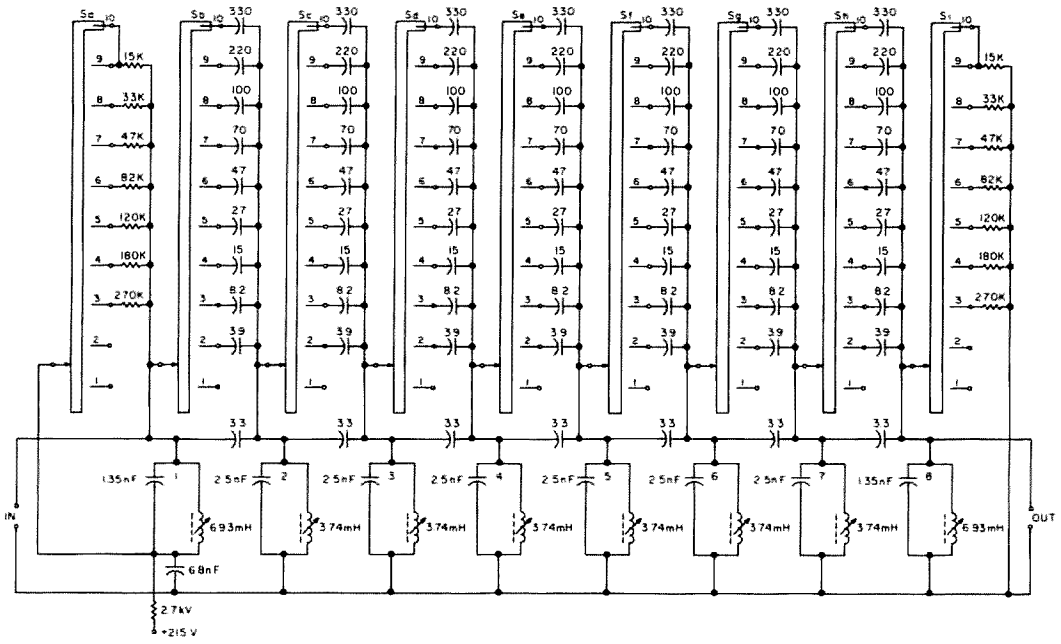

Fig. 3. The actual circuit diagram of the filter with selectable bandwidth. Capacitor values in picofarads unless designated nF (nanofarads). Sa through Si are the decks of the bandwidth-selector switch.

directly to the switch contacts and seeing what you get in the way of passband. No further alignment is necessary. In Fig. 3 you can see what I used, and Table 1 gives you the results I obtained. Position 1 gives the smallest bandwidth, 132 Hz, and this is with only the 3.3-pF capacitors in place. As stated, this switch position is intended for alignment only, but in practice it turned out to be useful as an operational position as well.

Switch decks Sa and Si are used to connect the proper loading resistors in parallel with the first and the last circuit. The values of these resistors can be found easily; they are equal to the reactance of the total coupling capacitance, C_2, in effect at each switch position. For positions 2 and 1, no resistor is required as the loss resistance of the coils themselves provides the loading.

You see that the resistors become smaller as the bandwidth increases. This means that the input resistance of the filter, as "seen" by the stage driving it, also decreases. And since the amplification of the stage feeding the filter is equal to the mutual conductance of the tube or transistor multiplied by the input resistance of the filter, this amplification also decreases as the filter bandwidth becomes wider. This effect is slightly compensated for by the fact that the insertion loss of the filter goes down as the circuits become more tightly coupled, but this compensation is only small because this filter loss is only of the order of one dB for the wider bandwidths.

This effect is also shown in Table 1. The total amplification between the input of the stage preceding the filter and the output of the filter was measured for the different switch positions. The amplification in switch position 2 was put at 0 dB as a reference. The table shows what happens in the other positions. Actually, the value in position 10 should be more than −21 dB, but I chose to use the same loading resistance, 15k Ohms, for positions 9 and 10 in order to keep the total amplification from going down too much. The underloading in position 10 is noticeable as a slight ripple in the passband that does no harm.

I first intended to make the total amplification the same for all switch positions by switching in suitable resistive attenuation networks on the output side, and I reserved a switch deck for that purpose. It is the one nearest the front panel of the receiver in Photo B. But I finally rejected that refinement. The difference in receiver gain is hardly noticeable under the compensating influence of the automatic gain control. Only if you would like to have the S-meter calibration hold for all switch positions should you include the loss equalization. My S-meter is used only as an uncalibrated indicator.

Table 1 gives the measured bandwidth at −6 and −60 dB with respect to the maximum in the passband. From that, the shape factor is computed and it approaches 1.7 when the bandwidth is 2.70 kHz or wider. A very good figure, I think.

The shape of the filter attenuation characteristic was also measured. Fig. 4 shows two of the curves, for switch positions 5 (1.11 kHz) and 9 (7 kHz). It is shown clearly that the upper limit of the passband remains at about 52 kHz and the lower limit moves down as the bandwidth increases.

Position of the switch	1	2	3	4	5	6	7	8	9	10
Bandwidth at −6 dB (passband)	132 Hz	177 Hz	361 Hz	638 Hz	1.11 kHz	1.91 kHz	2.70 kHz	3.64 kHz	7.03 kHz	9.36 kHz
Bandwidth at −60 dB	580 Hz	715 Hz	1.04 kHz	1.50 kHz	2.20 kHz	3.41 kHz	4.71 kHz	6.32 kHz	12.2 kHz	16.0 kHz
Shape factor B_{60} dB/B_6 dB	4.4	4.0	2.9	2.3	2.0	1.8	1.7	1.7	1.7	1.7
Attenuation at f_0 with att. in pos. 2 as reference	−7.0 dB	0 dB	−6.5 dB	−5.5 dB	−6.5 dB	−8.5 dB	−12 dB	−15 dB	−21.5 dB	−21 dB

Table 1.

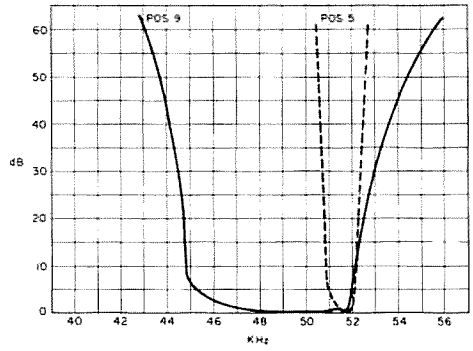

Fig. 4. Measured filter response in switch positions 5 and 9. Response continues beyond −60 dB, but this could not be measured with the simple test equipment at PAØSE.

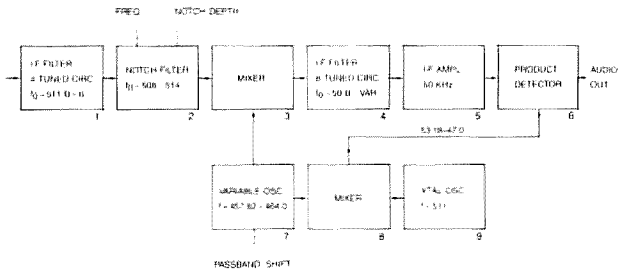

Fig. 5. Block diagram of second and third i-f sections in PAØSE's receiver, incorporating passband shift. Frequencies in kHz.

The attenuation extends beyond 60 dB but I was unable to measure deeper down with the unsophisticated test equipment in my home lab. You can see in Fig. 3 that the "cold end" of circuit 1 is not grounded but connected to +215 V. It is decoupled by a 68-nF capacitor. This was done because the filter is fed from a pentode tube and it receives its anode voltage via the first circuit.

Finding Q_0

The unloaded quality factor, Q_0, of the parallel tuned circuits is also measured using the setup in Fig. 2. C_1L is the circuit under test. First find frequency f_0 of maximum response. Now detune the generator slowly to the frequencies at which the voltage is −3 dB (0.707 times) with respect to the maximum voltage. The frequency difference between those two points is designated b.

We now find Q_0 from $Q_0 = f_0/b$. A frequency counter is almost a must since the frequency differences we deal with are very small. The coils I used have a Q of about 370, as mentioned earlier. That means that at 50 kHz the frequency difference between the −3-dB points is 50,000/370 = 135 Hz.

We do not want to load the circuit by the internal resistances of generator and indicator. This is done by keeping C_2 and C_3 small. To make sure the extra loading by generator and indicator does not influence our result, we can repeat the measurement using the next bigger or smaller value for C_2 and C_3. If the value of Q_0 is the same in this case, we know we have a good result.

Passband Shift

The receiver in which the filter is used also features passband shift, or passband tuning as it was called earlier. This means that the passband can be shifted up or down over the signal without affecting the tuning of the receiver. In conjunction with the passband width selection, this offers unique possibilities for getting rid of QRM. With one hand we move the bandwidth switch to progressively smaller passbands and with the other we adjust the passband shift to put the passband in the optimum position over the received signal.

In my receiver I even have an adjustable notch filter in the 511-kHz i-f preceding the final 50-kHz i-f. This was put in when I had the fixed 2.7-kHz filter at the final i-f. The notch could be used to remove an interfering heterodyne on the wanted signal. Since I replaced the 2.7-kHz filter with the one described here, there is no need to touch the notch filter any more.

How the passband shift is effected will not be described here in detail. Only the principle will be shown, with the help of the block diagram, Fig. 5.

The receiver has a first tunable i-f of 3.5 to 4.5 MHz. The second i-f is 511 kHz. Selectivity on this frequency is provided by a bandpass filter with four tuned circuits. Bandwidth is about 6 kHz. This filter is indicated as 1 in Fig. 5. It is followed by a notch filter (2) with adjustable rejection frequency and notch depth. (As mentioned, this is more or less superfluous with the variable i-f filter now used.) The second i-f at 511 kHz is converted to 50 kHz in the mixer (3). This frequency is the difference between the 511-kHz signal and the oscillator signal from the variable-frequency oscillator (7). This oscillator affects the passband shift, and its frequency can be varied between 457.82 and 464.0 kHz.

This means that a signal at the center of the second i-f at 511 kHz can be shifted between 511−457.82 = 53.18 kHz and 511−464.0 = 47.0 kHz. That is to say, the spectrum of input signals offered to the third i-f filter at 50 kHz can be shifted upwards and downwards.

The output signal from the switchable bandpass filter (4) is amplified (5) and presented to the product detector for conversion to audio. In order to keep the tuned frequency the same when shifting the passband, the oscillator signal for 6 (bfo signal) should be shifted the same amount up or down as the shift of the input signal for the filter (4).

This is realized by mixing the signal from oscillator 7 also with that from a crystal oscillator at 511 kHz (9) in the mixer (8). The output signal of 8 is filtered and it has a frequency between 47.0 and 53.18 kHz, just the same as the signal at the filter input that resulted from a 511-kHz signal at the second i-f.

So although it looks as if the passband of the filter is moved back and forth over the signal, in reality the signal is moved up and down at the filter input and the bfo frequency is moved with it.

There are a few things to be watched with this system. One is that the crystal oscillator (9) and mixer (8) have to be well screened because the 511-kHz signal is in the middle of the second i-f and even a small leakage signal means a standing signal in the receiver. It is always zero beat with the bfo frequency signal so it won't be heard, but it deflects the S-meter.

Also, the output signal of the mixer (8) must be well filtered; otherwise birdies will be heard when the passband shift control is operated.

Helpful in this respect also is keeping the signal from the oscillator (7) in the mixer as small as possible. I managed to get rid of birdies completely after I installed a single-section low-pass filter with a cutoff frequency of about 55 kHz between the mixer and the product detector. ■

Curious About Code?

Learn (or improve) Morse from your TRS-80! You'll never find a more patient teacher.

This interactive program will teach or improve Morse-code skills. The program, written in Basic and Z-80 assembly language, puts out Morse code as a sequence of audible dots and dashes via the computer's cassette port. By attaching a small amplifier and speaker or simply a pair of earphones to the cassette port (see Fig. 1), one can listen to the code. The program will work with either Model I, III, or 4 Radio Shack TRS-80 computers and could be modified to work with other computers as well.

The program user is presented with several self-explanatory menus. The principal menu gives a choice of six options:

1. Setting the code speed (defaults to 10 words per minute)
2. Setting the audio pitch (defaults to 1000 Hz)
3. Typing arbitrary characters and listening to the corresponding code, which is also displayed as dots and dashes on the monitor screen
4. Listening to a sequence of ten randomly-generated five-character words
5. Listening to the code of randomly-generated characters one by one and then typing a guess (after each guess the program indicates whether the guess was correct and if not, what it should have been; after generating 20 characters the computer gives you a score of how many characters were correctly guessed and what the average delay of your response was)
6. Listening to the code of a previously-stored sentence

Options 4 and 5 allow selection of a subset of characters (e.g., A, B, F, Z, and 7) from which the random choice is made by the program. After listening to the randomly-generated sequence of ten 5-character words (menu option 4), you have the choice of repeating the same sequence, displaying the words on the monitor, or generating a new sequence.

The Basic program shown in Program listing 1 displays the menus and prompts the user. It also sets the time relations between dots, dashes, and pauses between characters and words. The program sets the length of a dash as three times the length of a dot, space between words as seven dot lengths, etc. These and other time relations can be changed by modifying program lines 350–390.

The assembly-language portion of the program shown in Program listing 2 accepts the ASCII value of a character and translates it into a Morse-code sequence of dots and dashes by accessing the code table stored in memory by the Basic section of the program (lines 1140–1260). Two bytes describe each character. The first byte gives the number of dots and dashes—n (if n is larger than 8, then the character will be ignored); the n bits of the second byte from the most to the least significant bit correspond to dots (0s) and dashes (1s). For example, the two bytes de-

Program listing 2.

scribing the code for the letter Y (- . - -) would be 04 and B0 (hex) = 10110000 (binary). The four least significant bits do not matter in this case and can be set to 0s or 1s because Y contains only three dashes and one dot for a total of four symbols. The dots and dashes are "peeled" off by left shifting the second byte and checking the carry register after each shift.

The program as listed here will run on the Radio Shack Model I or Model III computer (also Model 4 in Model III mode) with one disk drive and 48K of RAM. The machine-language part of the program should be assembled and loaded into memory, where it will be accessed by the Basic program. Both parts of the program can easily be modified to other configurations (cassette, 16K RAM, etc.).

For information about availability of derived programs on disk or cassette for such configurations, and also for 6502-based computers (e.g., KIM 1), send an SASE to the author. A ready-to-run, single-density disk with the machine-language program stored as DATA statements for Model I, 48K, is available from C & R Electronics, PO Box 217, Holmdel NJ 07733, for $10.95 ppd. (New Jersey residents add 6% sales tax.) You can convert the disk to the TRS-80 Model III or Model 4 double-density format by means of the Radio Shack CONVERT utility.■

WARC, Rest, and Play

Adding 10-MHz capability to your Yaesu FT-101Z is a simple step-by-step process. In just a few hours, you can join the fun on our newest amateur band.

The Yaesu FT-101Z/ZD can be modified to add coverage of the 30-meter band, allowing operation in the newly-authorized amateur segment as well as reception of WWV at 10.0 MHz. Frequency coverage following this modification ranges from 10.0 to 10.5 MHz.

When I started looking into modifying this rig, it appeared at first that adding 30 meters would not be an easy task. As most of the bandswitch lugs in the JJY/WWV position are not provided in the transmitter PA section, it is not possible simply to convert WWV operation to 10 MHz and enable the transmitter. Additionally, local oscillator and mixer components are not provided for the AUX position, although all switch lugs are in place. Therefore, a combination of WWV and AUX was used for this modification.

The WWV section was modified to receive 10.0 to 10.5 MHz rather than 5.0 to 5.5 MHz as is normally the case. Next, the bandswitch lugs for WWV and AUX were jumpered to duplicate receive operation in both bandswitch positions. Finally, the transmitter section was enabled in the AUX switch position. The result was reception of the first 500 kHz of the 10-MHz band in both WWV and AUX switch positions, with transmit operation possible only in the AUX position. This technique prohibits the addition of any future bands, unfortunately, as all switch positions are taken; however, it was the only way to add a new band to the FT-101Z/ZD.

In the FT-101Z/ZD, the 5.0-to-5.5-MHz vfo signal is mixed with a signal generated on the premix local board from a crystal oscillator. By replacing the crystal with a 24.4875-MHz crystal, the output of the mixer after modification will range from 18.9875 to 19.4875. This output signal will then be passed through a bandpass filter on the premix board to allow selection of the difference frequencies only. Following the bandpass filter, this signal is mixed with the incoming rf to produce an i-f frequency of 8.9875 MHz. This modification consists of changing the local oscillator frequency to 24.4875 MHz by replacing a crystal and a capacitor in the oscillator circuit.

Photo A. The FT-101Z.

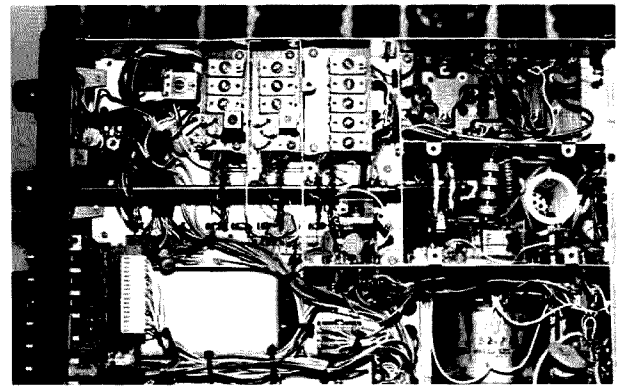

Photo B. Underside of rig showing the two new trimmers installed.

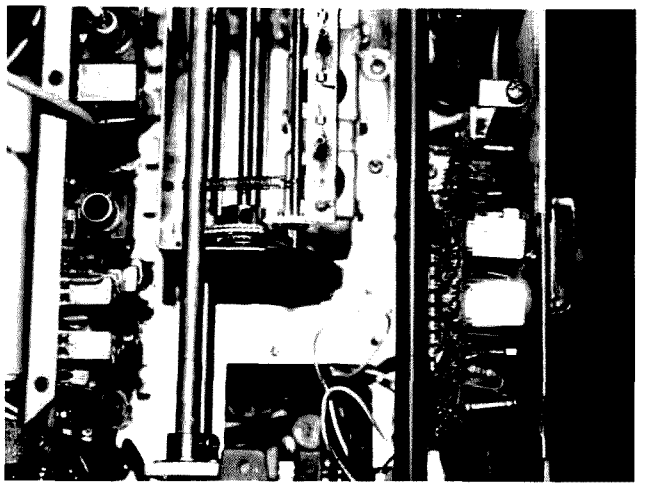

Photo C. The local board on the right and the premix board on the left, near the front of the FT-101Z.

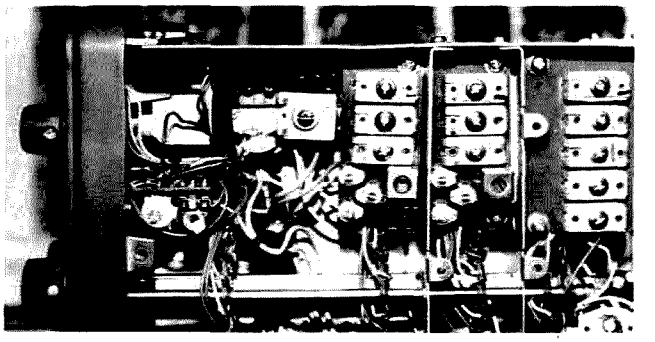

Photo D. The new trimmer capacitor may be soldered directly to the trimmer unit A circuit board.

Next, the bandpass filter frequency is shifted up to approximately 19 MHz by changing a capacitor. Additionally, trimmer capacitors must be added to the rf-input section of the receiver and the driver section of the transmitter; this is necessary because the 40-meter trimmer was simply borrowed for WWV operation in the receiver section before modification, and no trimmer was provided for the driver section. Finally, changes must be made to the final amplifier stage to allow the tank circuit to resonate at 10.0 to 10.5 MHz.

To modify the FT-101Z/ZD, proceed as follows:

1) Remove the top cover and locate the local board (PB-1965). This board is mounted vertically on the right side near the front (Photo C). Remove the board and replace X10 with the new crystal and C40 with a 160-pF silver mica capacitor. Jumper pins 12 and 13 of the edge connector, being careful to keep all solder and jumper wire away from the pins so as not to restrict plugging the board back into its socket. Replace the local board.

2) Locate the premix board (PB-1962), mounted vertically to the left of the local board. Remove the premix board and replace C27 with a 100-pF silver mica capacitor. Preset transformers T13 and T14 by first backing their slugs out all the way in a counterclockwise direction and then turning them one turn in a clockwise direction. Replace the premix board.

3) Turn the rig over and remove the bottom cover. Carefully remove the shields covering trimmer units B and C and the final amplifier compartment. Note that the bandswitch runs from S1A to S1E and S2A to S2D, with S1A closest to the front of the rig. On section S1B, first remove any jumper that may be connected between lug 11 (AUX) and the wiper arm, and then remove the jumper between lug 3 (40 meter) and lug 10 (WWV). Now add a jumper between lugs 10 and 11. Add an 80-pF trimmer in parallel with a 300-pF silver mica between lug 10 and the common side of trimmer A unit. The trimmer can be mounted by soldering its lug directly to the underside of the circuit board (Photo D).

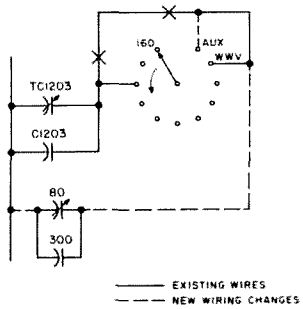

Fig. 1. Trimmer A unit.

4) On S1C, remove any jumper that may be connected to lug 11 and tie lugs 3 (40 meter) and 11 (AUX) together (Fig. 2). The trimmer B unit will have to be removed temporarily to get at the switch lugs. Simply remove the screws that hold the circuit board in place and carefully move trimmer unit B out of the way; there is no need to disconnect any wires.

5) On S1D, remove any jumper that may be connected to lug 11. Then add an 80-pF trimmer in parallel with a 270-pF silver mica between lug 11 (AUX) and the common side of trimmer unit C. The common side can be traced to an unused lug on S1E. The trimmer may be mounted by soldering directly to this unused lug (Fig. 3).

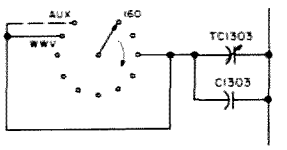

Fig. 2. S1C.

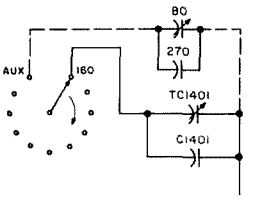

Fig. 3. Trimmer C unit.

6) S2A through D are located in the final compartment. Sections A and B are on opposite sides of the switch wafer located nearest the front, while sections C and D are on the last wafer, closest to the rear. Add a 560-pF capacitor between the AUX lug on S2A and ground. (See Figs. 4 and 5.)

7) On L1, the plate PA coil, connect a new tap 3 turns from the 40-meter tap (towards the 20-meter tap). Connect this tap to the AUX lug of S2D with #18 wire or larger. The connection to L1 can be made by carefully pushing in the turns adjacent to the desired tap point and then soldering to that point; a much easier alternative is to parallel the 40-

THE SMART WAY TO SAVE YOUR *73*

You'll find all your favorite issues of **73 for Radio Amateurs** in minutes—and in great condition—with smart-looking binders or file cases from Jesse Jones.

Sturdy, protective file cases make for easy access to each issue, while rugged binders allow magazines to lay flat for easy reference. Both hold 12 issues, are custom-designed in green with gold spine lettering, and are **unconditionally guaranteed.**

Order today!
File Cases: $6.95 ea.; 3/$20; 6/$36.
Binders: $8.50 ea.; 3/$24.75; 6/$48.

YES! Please send me protection for my 73:

meter tap, but this results in the plate and loading controls operating near the limit of their ranges.

This completes the modification of the rig with the exception of alignment at the new frequency. To peak the various coils on the local and premix boards, a means of sensing rf up to about 25 MHz will be necessary. If a wideband oscilloscope is not available, an rf probe can easily be constructed for use with either an inexpensive scope or high-impedance meter such as a VTVM or FET voltmeter (Fig. 6).

To align the rig following modification, place the bandswitch in the AUX position and adjust T10 on the local board for maximum output at pin 1 on that board. Now tune the vfo to 10.1 MHz and peak T13 and T14 on the premix board for maximum output from that board; J301 may be used as an output port. This is a very difficult adjustment to get at as the local board is located close and must remain plugged in. Use a small screwdriver and be patient!

Following adjustment of T13 and T14, the output level from the premix board should remain fairly constant throughout the vfo's range as this is a bandpass filter. I found this adjustment to be not very critical, however, with merely peaking T13 and T14 being sufficient. If the receiver's calibrator marker signal can be heard at 10.1, the S-meter may be used to make this adjustment (the preselect control should peak somewhere in the 10-meter range).

Once T13 and T14 have been adjusted, you should be able to hear the receiver's marker at 10.1 MHz although the preselect control probably will have a broad peak or two peaks. You need to tune the preselector to that peak which increases when you adjust newly-added trimmer A (connected to S1B). If the signal goes down when you adjust the new trimmer, you have the preselect control tuned to the wrong peak. Maximize the signal by adjusting the vfo, the preselector, and the new trimmer A. One distinct peak should be observed now when adjusting the preselect control. To observe the best peak on the S-meter and to aid in fine adjustments, the front panel agc switch should be in the fast position.

Modification and alignment of the receive section is now complete, and 30-meter signals should be heard with an antenna connected to the rig.

Alignment of the transmitter section consists only of adjusting the newly added trimmer C (at S1D) to peak the driver output. This is done with the vfo set to 10.125 MHz and the preselector peaked for maximum receive strength of the calibrator signal. Without adjusting the preselect control further, peak the new trimmer C for maximum drive by observing rf output or PA current. Use as little drive as possible, keeping PA current below 100 mA, and resonate the plate and loading controls as soon as output is obtainable. Be careful not to maintain a key-down condition for long periods of time. Increase the drive level to full output, recheck plate and loading, and peak new trimmer C a final time. This completes alignment of the transmitter section.

No modification is required to make the digital counter in the FT-101ZD operate correctly, as it simply reads the new frequency at the output of the bandpass filter and converts this to 10.0 MHz. Sensitivity and power output are comparable to the other bands, and no problems were encountered during tune-up or normal operation. The preselect control should peak somewhere in the 10-meter band area, while the plate and loading controls should be near mid-range. ■

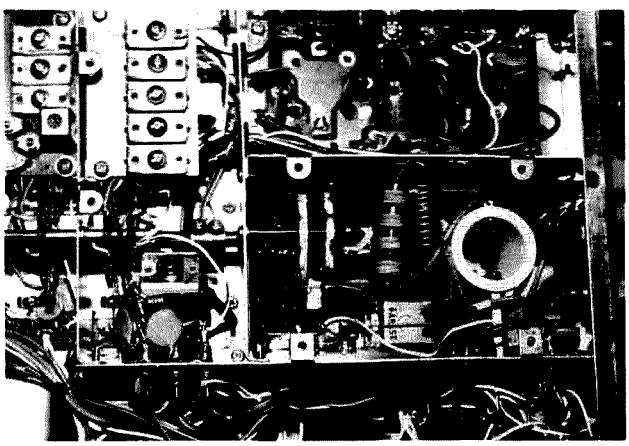

Photo E. The new trimmer C, mounted on S1E. The final amplifier compartment can be seen to the right.

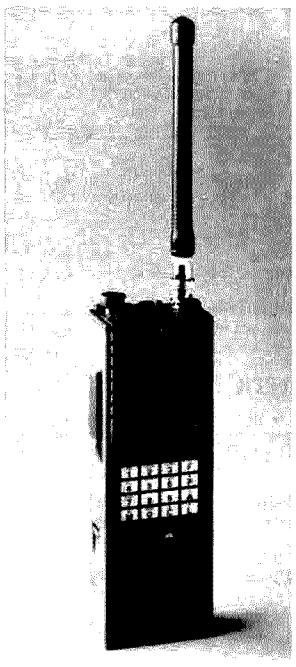
Parts List

X10—24.4875 MHz, HC-18/U package
C40—160-pF silver mica
C27—100-pF silver mica
Two 80-pF trimmer capacitors (Arco 462 or equivalent)
270-pF, 500-volt silver mica
300-pF silver mica (270 pF in parallel with 36 pF may be used)
560-pF silver mica, 500 volt

NEW PRODUCTS

HEATHKIT HD-1422 ANTENNA NOISE BRIDGE

Heath's new HD-1422 Antenna Noise Bridge is an antenna tuning aid which helps reveal the cause of any mismatch between a station's transmitter and its antenna. A tone-modulated broadband noise signal is generated in the HD-1422 and coupled to an impedance bridge. Using the receiver as an indicator, the impedance bridge is used to measure the reactive components of the antenna's impedance. This allows each antenna to be trimmed to a favorite operating frequency. Additionally, the HD-1422 can be used to preset an antenna tuner, to tune a quarter-wave transmission line, and to measure the value of unknown capacitors and inductors.



For more information about the HD-1422, get Heathkit's new catalog by writing *Heath Company, Dept. 150-592, Benton Harbor MI 49022.* In Canada, write *Heath Company, 1020 Islington Avenue, Dept. 3100, Toronto, Ontario M8Z3.*

MIDLAND LMR 16-CHANNEL HT

A new 16-channel programmable frequency-synthesized portable two-way FM radio has been introduced by Midland Land Mobile Radio. The radio features a front-panel keypad and a liquid-crystal display. VHF models cover 136-174 MHz, and UHF models cover 406-520 MHz; both VHF and UHF models have a switchable output of 5 Watts and 1 Watt.

Tone-coded squelch is a standard feature, and each channel may be separately programmed for any EIA tone. A DTMF option is also available which temporarily stores data entered from the keypad and automatically transmits it when the push-to-talk switch is activated. Other options include an external speaker/microphone with an antenna jack, a programmable scanner, and 600-mAh or 1000-mAh nickel-cadmium battery packs.

For complete details, contact *Midland LMR, Marketing Department, 1690 N. Topping, Kansas City MO 64120.*

Midland LMR's 16-channel FM portable radio.

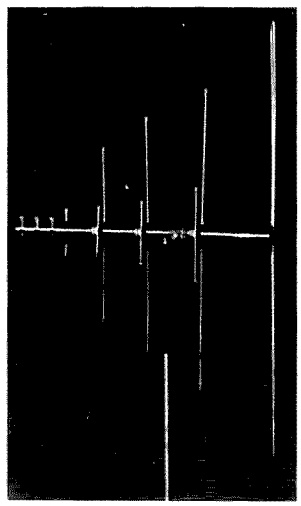
KENWOOD TM-2570A, TM-2550A, AND TM-2530A

Trio-Kenwood Communications has announced three new 2m FM radios. The TM-25 series offers a choice of three power levels: 70 Watts with the TM-2570A, 45 Watts with the TM-2550A, and 25 Watts with the TM-2530A. The TM-2570A includes a built-in cooling fan.

All three models feature a back-lit 16-key DTMF pad, twenty-three memory channels which store frequency, offset, and subaudible access tone, and an automatic dialer which stores up to fifteen seven-digit telephone numbers.

The TM-25-series radios cover 142-149 MHz and are modifiable to cover 141-151 MHz. Available options include a 38-tone CTCSS encoder, a Digital Channel Link modem, a voice synthesizer, and a call-sign display.

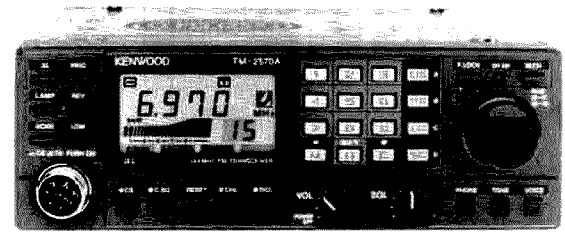
Complete information is available from *Trio-Kenwood Communications, PO Box 7065, Compton CA 90224; (213)-639-9000.*



FREE TOOL CATALOG FROM CONTACT EAST

Contact East is offering a free catalog of over 5,000 hard-to-find products for assembling, installing, and repairing electronic equipment. The catalog features precision hand tools, tool kits, test instruments, soldering supplies, and static-control devices.

To request your free catalog, write or call *Contact East, PO Box 786, North Andover MA 01845; (800)-225-5370.*



GROVE SCANNER BEAM

Grove Enterprises has introduced a new antenna for scanner enthusiasts. The Scanner Beam covers 30-960 MHz and includes a balun transformer, an offset pipe, and all necessary mounting hardware.

The Scanner Beam from Grove Enterprises.

For additional information, contact *Grove Enterprises, PO Box 98, Brasstown NC 28902; (800)-438-8155.*

Kenwood's 70-Watt TM-2570A.

VOCOM POWER AMPS

VoCom Products Corporation has introduced a new line of rack-mounted rf power amplifiers for continuous-duty applications such as repeaters or paging systems. Included in the line are models which run directly from 110/220-V-ac mains. Available output powers are 50, 100, and 200 Watts for both VHF and UHF frequencies. Ac-powered models may be configured for battery backup or automatic bypass in the event of a commercial power failure.

For further information, contact *VoCom Products Corporation, 65 East Palatine Road, Prospect Heights IL 60070; (800)-USA-MADE.*

ELECTRONIC SPECIALISTS COMPUTER PROTECTION

Electronic Specialists has introduced the Modem/Power/Static Pac, a protection device for portable computers. The unit combines a broadband ac power filter, a power spike suppressor, a modem spike suppressor and rf filter, and a static discharge plate. Filtered ac is available from both a standard 3-prong outlet and a CEE-22 universal computer power connector. Modem attachment is through modular RJ-11 connectors.

For more information, contact *Electronic Specialists, Inc., 171 South Main Street, Natick MA 01760; (800)-225-4876.*

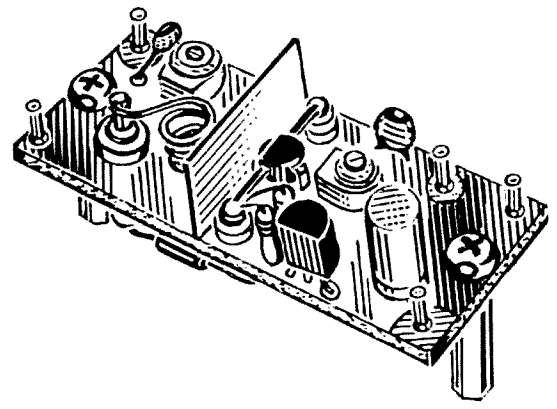
HAMTRONICS® GaAsFET PREAMPS

Hamtronics, Inc., has announced a low-cost miniature receiver preamplifier for the VHF and UHF bands. The LNW series of preamps uses a dual-gate GaAsFET for a typical gain of 18 dB and a noise figure of 0.8 dB.

A 40-page catalog describing the LNW preamplifier line and other Hamtronics products is available from *Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535; (716)-392-9430.*

PACCOMM TNC-200

PacComm Packet Radio Systems' TNC-200 is a licensed copy of the Tucson Amateur Packet Radio (TAPR) TNC-2 terminal node controller. Available as both an assembled unit and a kit, the TNC-200 features multiple connections, a choice of NMOS or CMOS chips, and full AX.25 version 1 and 2 compatibility.



PacComm also has put together partial kits for the TNC-200 which come with hard-to-find parts, a PC board, and an assembly manual. Cabinets and end plates are offered separately.

For further details, please contact *PacComm Packet Radio Systems, Inc., 4040 West Kennedy Blvd., Suite 620, Tampa FL 33609; (813)-689-3523.*

KALGLO PLUG-IN SURGE SUPPRESSOR

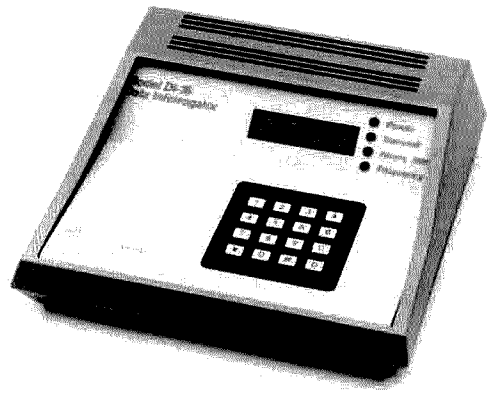
Kalglo Electronics' Mini-II is a compact surge suppressor that responds in 5 nanoseconds, suppresses 13,500 pulse-Amps, and has a capacity of 135 Joules. Clamping starts at 150 volts, and its filtering circuit removes 41 dB of noise at 10 MHz in common mode and 49 dB of noise in normal mode. Once plugged into a wall outlet, the unused receptacle receives the same protection as the two outlets on the Mini-II, giving three protected sockets.

For more information, write *Kalglo Elec-*

The LNW GaAsFET preamp by Hamtronics.

tronics Company, Inc., 6584 Ruch Road, Bethlehem PA 18017-9359; (215)-837-0700.

DI-16 REMOTE DATA INTERROGATOR



The DI-16 Data Interrogator from Communications Specialists is designed for remote retrieval of accumulated time and hit information from the TP-38 Shared Repeater Tone Panel. It also may be used to remotely access the TP-38 to enable or disable repeater subscribers. Hard-copy printout is available with a Radio Shack TP-10 serial printer, or the DI-16 may be connected to a host computer for information processing and air-time billing.

The DI-16 uses a sixteen-digit keyboard and has a high-visibility LED display. An automatic PTT keying circuit and an output port for serial communications are standard equipment.

For detailed information about the DI-16 Interrogator, contact *Communications Specialists, Inc., 426 West Taft Avenue, Orange CA 92665-4296; (800)-854-0547.*

HOW HAMS VIEW THEMSELVES

Six years of "Fun!" polls. That's a long stretch of time, to say the least.

I remember well the day I put together the first poll. I had just finished putting a new coil in my spark transmitter when my friend Horace pulled up the driveway in his 1912 Model T.

"Hi, John!" said Horace, as he folded down the rumble seat. "How's the mobile antenna project coming along? '

"Not bad," I replied. "But you wouldn't believe how many windings have to go into a 300-meter loading coil. . .real bear to wind."

"Think it'll work?" he asked.

"In theory it should. But whenever I attach the antenna to my Locomobile's rear bumper, it lifts the car's front wheels off the ground," I grumbled.

"Tough luck, OM," said Horace, as he played with my new mobile rig's coupler.

Okay, okay, I'm exaggerating, but it *has* been a long time.

This year, as in previous "Fun!" polls, we're retaining many old questions to track developing trends in our hobby and adding some new ones to keep up with the times. Whatever your views, send your responses to PO Box 73, Middle Village NY 11379. Or, if you've given up on the US Mule, you can transmit your answers electronically. My CompuServe ID is 70007,412 (CIS) or 76004,174 (EIS). My Source ID, if you prefer that system, is CPA117. You may also contact me via MCI Mail; just type my name at the "To:" prompt.

ELEMENT 1 BACKGROUND

1) Sex:
A) Male
B) Female
2) Age:
A) 15 or below
B) 16-21
C) 22-39
D) 40-59
E) 60 years and up
3) License class:
A) Novice
B) Technician
C) General
D) Advanced
E) Extra
4) Number of years licensed:
A) 1 year or less
B) 1-5 years
C) 6-10 years
D) 11-20 years
E) 21 years and up
5) Do you have a new (post-March '78) call?
A) Yes
B) No
6) How many hours a week do you devote to amateur radio?
A) 0-1 hour
B) 2-5 hours
C) 6-10 hours
D) 11-20 hours
E) 21 hours or more
7) Which HF band do you use most?
A) 80/75 meters
B) 40 meters
C) 20 meters
D) 15 and/or 10 meters
E) Don't operate HF
8) Which VHF/UHF band do you use most?
A) 6 meters
B) 2 meters
C) 220 MHz
D) 420 MHz and/or up
E) Don't operate VHF/UHF
9) Which mode do you use most?
A) SSB
B) CW
C) FM
D) RTTY
E) Other
10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenses.)
A) 0-$250
B) $251-$500
C) $501-$1,000
D) $1,001-$2,500
E) $2,501 and up

ELEMENT 2 SOCIAL CHARACTERISTICS

11) On the whole hams are:
A) too young
B) too old
C) just the right age
12) Do you like rock music?
A) Yes
B) No
13) Politically, how would you define yourself?
A) Conservative
B) Middle-of-the-road
C) Liberal

Comments: _____

14) Should we get rid of the ARRL?
A) Yes
B) No
15) How old were you when you first became a ham?
A) 15 or below
B) 16-21
C) 22-39
D) 40-59
E) 60 or above
16) Should the FCC increase the speeds on amateur CW examinations?
A) Yes
B) No
17) Do you own a home computer?
A) Yes
B) No
18) If you answered "yes" to question 17, which brand?
A) Apple
B) IBM
C) Radio Shack
D) Commodore
E) Other
19) Do you think that home computing is siphoning people (including youngsters) away from amateur radio?
A) Yes
B) No
20) Are hams getting dumber?
A) Yes
B) No
21) Do business interests deserve some of our virtually abandoned bands?
A) Yes
B) No
22) Should ham licenses have a minimum age requirement?
A) Yes
B) No
23) Should ham licenses have a maximum age requirement?
A) Yes
B) No
24) Should hams be subject to periodic retesting?
A) Yes
B) No

ELEMENT 3
OPERATING HABITS

25) If the users were restricted to data communication only (no phone or CW operation), would you be in favor of a no-code 220-MHz Digital-class license?
A) Yes
B) No
26) Would you be in favor of a no-code 220-MHz Digital-class ticket if it permitted phone operation in addition to data transmission?
A) Yes
B) No
27) Have you ever used a personal computer in connection with your amateur-radio activities?
A) Yes
B) No
28) Is it time to completely deregulate amateur radio by having the FCC turn over all responsibility for ham operation to the amateur community?
A) Yes
B) No
29) What do you think of people who view pay-television services with MDS converters and satellite dishes that are not approved by broadcasters?
A) They're skunks.
B) They're within their rights.
30) Should we get rid of, or reduce in size, the CW subbands?
A) Yes
B) No
31) Do you think DX nets have a place in ham radio?
A) Yes
B) No
32) Do you think nets in general have a place in ham radio?
A) Yes
B) No
33) The next time a ham operates from space, which band should he/she use?
A) 2 meters
B) 220 MHz
C) 450 MHz
D) An even higher band
E) Shouldn't bother to operate
34) If, while tuning across a band, you heard a net called "Jammers International" in progress, would you:
A) Jam it
B) Ignore it
C) Complain to the FCC or some other organization
D) Listen
E) Join it
35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes
B) No
36) If required, could you pass the FCC theory test for your license class?
A) Yes
B) No
37) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes
B) No
38) Are you fluent in any computer language?
A) Yes
B) No
39) If you answered "yes" to question 38, which language?
A) Basic
B) Pascal
C) Assembler
D) Machine
E) Other
40) Do you feel yourself competent to write a short Basic program?
A) Yes
B) No
41) Do you feel yourself competent to replace the finals in a transistor-type rig?
A) Yes
B) No
42) Do you solder together your own coax connectors?
A) Yes
B) No
43) Do you own a TVRO (home earth satellite) system?
A) Yes
B) No
44) Do you operate a packet-radio system?
A) Yes
B) No
45) What do you think of contesting?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it
46) What do you think of DXing?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it
47) What do you think of repeaters?
A) Great
B) Good
C) Okay
D) Don't like them
E) Despise them
48) What do you think of traffic handling?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it
49) If you heard an emergency net in progress, would you immediately join in and offer your services?
A) Yes
B) No
50) Have you ever secretly hoped for a minor disaster to strike your community just so you could demonstrate your radio skills?
A) Yes
B) No

SATELLITES

USING THE AO-10 APOGEE PREDICTIONS

Apogee predictions for the month of February are provided for three sections of the United States: Washington DC at 39N 77W, Kansas at 39N 95W, and California at 38N 122W. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

from page 4

the 14th of November, and the Fredericksburg "A" index jumped to a disturbed level of 22 on the 13th. Perhaps not coincidentally, there was a solar eclipse on the 12th and a solar-flux peak on the 15th. Of course there is no claim that the alignments caused the volcanism, but you do see some interesting events. The Mexican earthquake of September followed by one day a jump in the Fredericksburg "A" index to 28, and was shortly followed by a 90-degree alignment of Uranus and Mercury. . .and, by the way, it was only three days after that Hurricane Gloria began its rampage toward contact with New England.

One should bear in mind that I did not predict any of these natural disasters, but of the days between the 20th and 27th of September, I predicted propagations of Fair or Poor for six of the seven days. In November, on the four days between the 12th and 15th, I predicted Fair for two days and Poor for two days, which just happened to coincide with actual band conditions.

I think that circumstances point to the need for a closer look at these relationships and a concerted effort to attempt to rationalize them for purposes of communications efficiency and—hopefully one day in the future—for helping save lives and property.

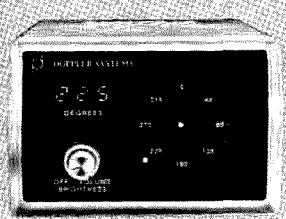
Jim Gray

ALL BAND TRAP ANTENNAS!

PRETUNED - ASSEMBLED ONLY ONE NEAT SMALL ANTENNA FOR ALL BANDS! EXCELLENT FOR APARTMENTS! IMPROVED DESIGN!

FOR ALL MAKES AMATEUR TRANSCEIVERS! GUARANTEED FOR 2000 WATTS SSB INPUT FOR NOVICE AND ALL CLASS AMATEURS!

COMPLETE with 90 ft. RG58U-52 ohm feedline, and PL259 connector, insulators, 30 ft. 300 lb. test dacron end supports, center connector with built in lightning arrester and static discharge. Low SWR over all bands - Tuners usually NOT NEEDED! Can be used as inverted V's - slopers - in attics, on building tops or narrow lots. The ONLY ANTENNA YOU WILL EVER NEED FOR ALL BANDS! NO BALUNS NEEDED!



80-40-20-15-10 - 2 trap - 104 ft. - Model 998D $79.95
40-20-15-10 - 2 trap - 54 ft. - Model 1001D . . . $78.95
20-15-10 meter - 2 trap - 26ft. - Model 1007D . . . $77.95

DIRECTION FINDING?

★ Interference Location
★ Stuck Microphones
★ Cable TV Leaks
★ Security Monitoring

★ VHF and UHF Coverage
★ Computer Interface
★ Speech Synthesizer
★ 12 VDC Operation

New Technology (patent pending) converts any VHF or UHF FM receiver into an advanced Doppler shift radio direction finder. Simply plug into receiver's antenna and external speaker jacks. Uses four omnidirectional antennas. Low noise, high sensitivity for weak signal detection. Call or write for full details and prices.

DOPPLER SYSTEMS, INC. 5540 E. Charter Oak, Scottsdale, AZ 85254 (602) 998-1151

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

TN HOMECOMING
FEB 1-2

The amateur-radio clubs of Johnson City, East Tennessee State University, and Carter County, Tennessee, will operate special-event station W4ABR on February 1-2, 1986, to celebrate "Homecoming 86" for the state of Tennessee. Frequencies will be the lower portion of all bands (including Novice) as conditions permit. Send an SASE to W4ABR, PO Box 3682 CRS, Johnson City TN 37602.

BATTLE OF KWAJALEIN AND ROI-NAMUR
FEB 1-10

The Kwajalein Amateur Radio Club will operate special-event station KX6BU from 0600 UTC on February 1, 1986, until 0600 UTC on February 10, 1986, to commemorate the 42nd anniversary of the Battle of Kwajalein and Roi-Namur. Frequencies will be: SSB—28.550, 21.350, and 14.250; CW—28.050, 21.050, 14.050, and 7.025. For $6.00, stations working KX6BU will be issued a certificate, a QSL, and a 64-page book describing the Battle of Kwajalein and Roi-Namur. $3.00 will bring a QSL and a certificate. All requests should be sent to: KX6BU, Box 444, APO San Francisco 96555-008.

PUNXSUTAWNEY PHIL
FEB 2

The Punxsutawney Amateur Radio Club will operate special-event station KA3CUY on Sunday, February 2, 1986, beginning at 9:00 am EST, to commemorate Groundhog Day 1986. Frequencies are 3.950 and 7.230 MHz ±QRM. KA3CUY will carry a recording of the official proclamation for the next 6 weeks' weather (as determined by Punxsutawney Phil). For a certificate, send a QSL and a large SASE to PARC, RD 5, Box 14, Brookville PA 15825.

LORAIN OH
FEB 2

The Northern Ohio ARS will hold its annual Winterfest on Sunday, February 2, 1986, beginning at 8:00 am, at Gargus Hall, Lorain OH. Admission is $2.00 in advance and $2.50 at the door. 8-foot tables are $7.00. Talk-in on 146.10/.70. For tickets or more information, write NOARS Winterfest, PO Box 354, Lorain OH 44052.

INVERNESS FL
FEB 8

The Sky High ARC will sponsor a ham flea market on February 8, 1986, from 9:00 am to 4:00 pm, at the Citrus County Fairgrounds auditorium, on US 41 south of Inverness FL. Admission is $1.50 in advance and $2.50 at the door. License exams will be given. Talk-in on 146.955. For more information, write SHARC Hamfest, PO Box 572, Lecanto FL 32661, or call Bob Gordon W1KUL at (904)-628-5045.

ST. CATHARINES ONT
FEB 8

The Niagara Peninsula ARC will hold its annual hamfest and flea market on Saturday, February 8, 1986, beginning at 8:00 am, at the UAW Hall, Bunting Road, St. Catharines, Ontario. Talk-in on 147.240/.840. For more information, contact NPARC, Box 692, St. Catharines, Ontario LR2 6Y3, Canada.

ORANGE NJ
FEB 9

The West Orange ARC will hold a hamfest on February 9, 1986, from 8:00 am to 4:00 pm, at the Orange Elks Club, 475 Main Street, Orange NJ. Admission is $3.00. Tables are $10.00. Talk-in on 146.55 and 224.80. For more information, call Mike at (201)-736-4611 after 5:00 pm, or call Rob at (201)-731-9506 or (201)-674-8148 any time.

MARLBORO MA
FEB 16

The Algonquin ARC will hold its annual hamfest/electronic flea market on Sunday, February 16, 1986, beginning at 10:00 am, in the Marlboro Junior High School cafeteria. Admission is $1.00. Tables are $7.50 in advance and $10.00 at the door. Seller setup begins at 8:30 am. Talk-in on .01/.61 and .52. For reservations or more information, contact the AARC, PO Box 258, Marlboro MA 01752; (617)-393-9920.

SPOONER WI
FEB 16

The Wild Rivers ARC will hold its midwinter swapfest on Sunday, February 16, 1986, from 10:00 am to 3:00 pm, at the Spooner Experimental Farm, east of Spooner WI on Highway 70. Exams will be given. Tables are available. Talk-in on 147.81/.21. For more information, contact Tom Young KD9FC, Route 5, Box 5239, Hayward WI 54843.

MANSFIELD OH
FEB 16

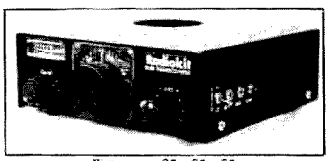
The Mansfield Midwinter Hamfest/Auction will be held on Sunday, February 16, 1986, beginning at 7:00 am, at the Richland County Fairgrounds, Mansfield OH. Admission is $3.00 in advance and $4.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Talk-in on 146.34/.94 (W8WE). For tickets or more information, contact Dean Wrasse KB8MG, 1094 Beal Road, Mansfield OH 44905; (419)-589-2415 after 3:00 pm EST.

FRIDLEY MN
FEB 22

The Robbinsdale ARC will sponsor the fifth annual Midwinter Madness Hobby Electronics Show on February 22, 1986, from 7:00 am to 2:00 pm, at Totino-Grace High School, 1350 Gardena Avenue NE, Fridley MN. Admission is $3.00 in advance and $4.00 at the door. 8-foot tables are $8.00; 1/2 tables are $4.00. Exams will be given. Talk-in on 147.60/.00 (KØLTC) and .52 simplex. For more information or to register, contact the Robbinsdale ARC, PO Box 22613, Robbinsdale MN 55422, or call Bob at (612)-533-7354.

GLASGOW KY
FEB 22

The Glasgow Swapfest will be held on Saturday, February 22, 1986, beginning at 8:00 am, at the Glasgow Flea Market Building, two miles south of Glasgow KY, just off Highway 31E. Admission is $2.00; no extra charge for exhibitors. The first table is free, and each additional table is $3.00. Talk-in on 146.34/.94. For more information, contact Mike Goad N4HCO, Route 4, Box 354, Glasgow KY 42141.



LA PORTE IN
FEB 23

The LaPorte ARC will sponsor a hamfest on Sunday, February 23, 1986, at the La Porte Civic Auditorium, La Porte IN. Admission is $3.00. Tables are $2.00 in advance and $2.50 at the door. Talk-in on .52 simplex. For more information, send an SASE to LARC, PO Box 30, La Porte IN 46350. For table reservations, mark your correspondence to the attention of KA9PHA.

DAVENPORT IA
FEB 23

The Davenport Radio Amateur Club will hold its 15th annual hamfest at the Davenport Masonic Temple, Brady Street (Highway 61) and 7th Street, Davenport IA, on Sunday, February 23, 1986, from 8:00 am to 4:00 pm. Admission is $2.00 in advance; $3.00 at the door. Tables are available by reservation for $7.00, with $2.00 extra for ac hookup. Table setup begins at 7:00 am. Talk-in on 146.28/.88 (WØBXR). For reservations, advance tickets, or more in-

CRUMTRONICS is our name, logging is our game.

REVIEW

AEA PK-64 PAKRATT™ DATA CONTROLLER

To borrow a phrase, the packet revolution has become a process of evolution. Mankind as we know it has evolved slowly, but it seems that new digital technologies are being implemented and improved almost overnight. The current trend in low-cost, versatile amateur equipment takes another giant leap forward with AEA's introduction of the PK-64.

At the 1985 Dayton Hamvention, the introduction of several packet-radio TNCs all but stole the show. The TAPR people were there touting the new low-cost TNC-2, Kantronics brought the Packet Communicator, and GLB and Heathkit displayed their wares. AEA stood quietly in the corner with the PKT-1 and showed off Doctor QSO™ to the delight of the convention-goers. Were those all-knowing smiles on the faces of the AEA staff?

With the public showing of AEA's PAKRATT system at the ARRL National Convention in Louisville, heads turned to see the latest developments in digital communications. What they saw was nothing short of the best thing to happen to that field since the Commodore 64 computer started selling for under $200!

New technologies require a growing period. The amateur community has been fortunate that the pioneers centered in the Tucson, Vancouver, and Washington DC areas have developed digital communication on the ham bands at virtually no cost to the amateur fraternity as a whole.

Growth in any new mode really begins when gear becomes commercially available. The PKT-1 began the movement and continues as a solid, commercial-grade TNC useable with any computer. The PK-64 applies the technology to the most favorite ham-shack machine—the Commodore 64. It does it at a price ($220) that should certainly prove to be "popular" with the ham community.

If I started telling you about all of the features of the PK-64, *73* would have to add a special section just to hold this review. The versatility and capabilities of the unit are almost overwhelming.

I can simplify much of this by suggesting that you check the back issues of *73* for my reviews of the CP-1 computer patch and MBATOR software from AEA. You see, PAKRATT not only operates packet like a champion, it gives you CW, RTTY, ASCII, and AMTOR operation all in one package! In my shack, it replaces several software packages and at least two interfaces.

The box containing the PK-64 is styled in the same fashion as the PKT-1 and CP-1. It is small in stature and is deeper than it is wide. The front panel is uncluttered. Depending on whether you have the optional high-frequency modem (HFM-64) installed, the front panel includes a DCD (data carrier detect) and PTT LED. With the HFM-64 installed, a threshold control and a tuning indicator are visible. Otherwise, just a red window and snap-in hole cover round out the front of the unit.

Emerging from the side of the PK-64 is a shielded ribbon cable designed to connect to the C-64 expansion port. That's the same one you use to plug in game and program cartridges. The familiar 5-pin connectors for radio-interfacing, audio-in, and external-speaker jacks are located on the rear panel. An external 13-volt-dc adapter is supplied and plugs into a rear connection. I had no trouble hooking the unit up to operate with several radios, including my IC-2AT.

With the PK-64 connected and everything powered up, a simple SYS command brings the unit to life. Now the real fun begins! The main menu looks similar to that of the MBATOR software package on which the PK-64 program is based. Selecting "P" for packet gets us to that mode and allows us to gain access to an options menu.

The touch of a function key brings a menu with many options up on the screen. Rather than using the traditional TAPR command mode to set many of the parameters (particularly the ones you seldom change), you need only use the cursor keys to highlight the option you wish to change. On/off functions are toggled with the return key. Numeric inputs are entered from the keyboard followed by a return. The TAPR names like CONOK for "connect OK" are used or are very close so there is no need to learn a new language.

Some of the options used in RTTY and AMTOR must be accessed through this menu as well. That's a very minor inconvenience since it requires coming back through the packet display to access them. There are only a handful of commands you will normally input through the command mode in packet. Connect and disconnect instructions are the major ones. "MY" followed by a space and your callsign sets that parameter. Incidentally, your custom settings can be saved to disk or cassette for recall at another time.

The PK-64 offers the standard beacon mode. The beacon text (BTEXT) is input via the command mode. There's also a neat feature that utilizes a message called CTEXT. That stands for "connect text." With the options set properly, your PK-64 becomes a packet answering machine. When a station connects, the PK-64 sends a message of your choosing, normally inviting the connecting station to leave a message for you and then disconnect.

Perhaps if you attended the Louisville convention you heard the sound of the "connect siren" in the PK-64. It sounds a bit like an "end of the world" alarm—guaranteed to get the attention of even the soundest sleeper.

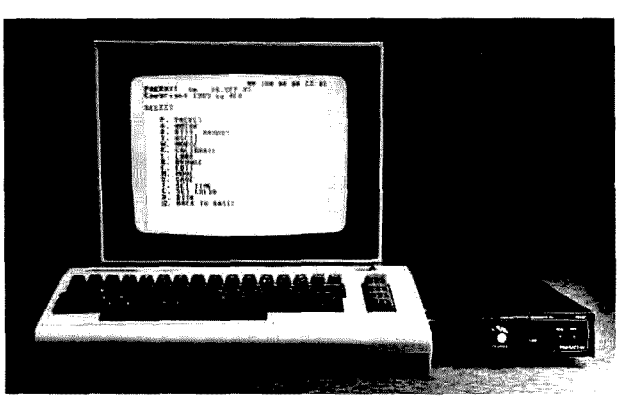
As in other modes, both a transmit buffer and a receive buffer can be activated. The receive buffer will hold about 20,000 characters. The review and editing features of the software allow you to manipulate the received text in any form you like. You have access not only to the QSO buffer but also to 10 message buffers. Text can be moved around from one buffer to another using the special editor. Actually it's a rather complete word processor that allows editing, saving, and loading.

The path used to connect is displayed in the header of connect messages. You can elect to stamp connected and monitored packets with just the time, the day and time, or the month, day, and time.

I can't conclude the discussion of features without telling you about two of my favorites. In the packet mode, the PK-64 will keep track of the number of unacknowledged packets you have sent. I frequently work over paths that are very marginal, particularly during daylight hours. The counter keeps me instantly informed in the event the packets start backing up. There is also an on-screen oscilloscope showing mark and space tones (more of a gee-whiz feature than it is useful). A perfectly-tuned signal makes the pattern look just like it should.

I'd like to switch into overdrive for a moment and talk about using the PK-64 on HF. The unit I tested included the optional HFM-64 module. It is a modem that uses the same technology present in the CP-1 computer patch. Normally, for the AFSK signals used on VHF operations a much simpler modem will work quite well. With the reduction in signal-to-noise ratios and additional interference present on the low frequencies, such simple modems don't perform well.

I've read many accounts of high frustration levels encountered by others trying to tune packet signals on the popular 20-meter packet frequency (14.103 MHz). I've done a limited amount of work there and have found it to be much more difficult than working on VHF.



Preparing to be quite skeptical, I connected the PK-64 to an R-600 receiver—not the best or easiest radio to tune for FSK signals. A quick check of the frequency revealed packet activity and I went to work tuning it in. Just as with the CP-1, the HFM-64 module made accurate tuning of the signal quite easy. I had my first packet station tuned in and printing within 30 seconds! Appropriately, it was Hank W@RLI's bulletin board. I enjoyed many other QSOs with similar ease in tuning. The only problem I had was the "bursty" nature of the packet signal as opposed to the continuous tone from a RTTY station.

If this were all the PK-64 did, it would have to be one of the best values in amateur radio today. But you must not forget that it works equally well on CW, RTTY, ASCII, and AMTOR. With the unit hooked up to my 2AT, I particularly liked being able to operate packet and traditional RTTY from one setup. We have several RTTY mailboxes on 2 meters in addition to the packet activity. All I had to do to switch between the two modes was to go to the option menu, select HF for band (setting the modem to standard mark and space frequencies), and then go back to the main menu and select RTTY mode.

Take a good look at the PK-64. For maximum effectiveness, I highly recommend the optional HFM-64 module. Both pieces come to about $320 total amateur list. For those without a Commodore 64 and not well equipped for assembling a TAPR TNC-2 from the ground up, AEA has introduced the PK-80. *73* will keep you posted on the latest developments.

Information on the PK-64 PAKRATT system is available from *Advanced Electronic Applications, Inc., PO Box C-2160, Lynnwood WA 98036; (206)-775-7373.*

AEA's PK-64 PAKRATT.

CW TRAINING FOR THE APPLE

Learning Morse code has always been one of the less enjoyable steps in obtaining a ham ticket. C.W. Tutorsoft and C.W. Testmaster, written for the Apple II family of computers by Twin Oaks Associates, can make learning "the code" a rather enjoyable experience, especially if you or someone you know is one of the growing number who are attracted to amateur radio after being first exposed to the world of computers.

The user's guide and study manual supplied with the program state that C.W. Tutorsoft and its companion, C.W. Testmaster, are compatible with Apple II, II+, IIc, and IIe computers having a minimum of 48K of RAM and one disk drive. The program will also run on an Apple III computer using a pre-booted emulator. An Apple IIe system was used for this evaluation, throughout which the programs performed flawlessly. For those of you interested in the finer details of the software, these programs utilize the DAVID-DOS disk operating system licensed from David-Data, Inc., to provide fast disk access during program execution.

Written by Dr. Thomas F. Linde KZ@T, C.W. Tutorsoft is an exceptionally fine training program which trains the user by combining the audible CW tones with characters printed on the Apple's high-resolution screen as the various groups of characters are taught. This method is in contrast to the usual audio-cassette method of a "teacher" speaking the character name before and after the CW version. This visual/aural approach seems much more natural since in most cases an operator will write or type a CW message as it is received.

The program is designed to grow with the user as he/she becomes more proficient. Each program section (or Focus Menu, as the author calls them) allows the user to vary the speed and pitch of the CW while tackling various types of lessons. These menus will serve the would-be Novice or the Extra-class operator alike, offering four major areas of study: (1) the standard alphabet lessons and drills; (2) small, medium, and large or complex words to teach word recognition; (3) call-sign recognition to prepare for FCC code tests; (4) QSO phrases to help with on-the-air "conversation" and again to make the FCC exams easier. Each section allows the user to select either Novice, General, Extra, or "Good Grief!" speeds to study the code.

C.W. Tutorsoft is an ear-training program. Within each review, the user must type the received letter or phrase on the keyboard. The program ignores any response entered prior to the completion of the material being sent. In each review, the program randomly sends you the Morse-code material contained in the study section preceding it. Your task is to type what you've just heard onto the keyboard. In each review, the program scores your performance and will send you on to the next lesson if your score exceeds the passing mark.

The next step up from C.W. Tutorsoft is its companion program, C.W. Testmaster. Following much the same ear-training technique as C.W. Tutorsoft, Testmaster goes a step beyond by providing users with an opportunity to copy various random QSO-type drills. Additionally, the program provides two distinct QSO messages which the user is tested on. One is a randomly-generated message which draws 13 specific pieces of information from a data pool of appropriate possibilities. The second QSO message is programmable, allowing the user to select his/her own variables for the drill. Both of the QSO exercises are followed by a completion quiz to test the student's understanding of the material presented.

Both C.W. Tutorsoft and C.W Testmaster are well-written, well-documented programs. Each sells for $30.00, a reasonable price especially when compared to other computer-aided instruction programs for the Apple. A minor drawback attributed to the use of a customized disk operating system is the inability of making backup copies of either program. Before purchasing either program, you may want to contact the folks at Twin Oaks to check on their policy about backups. All in all, I think you will find these programs extremely useful in learning CW for the first time or preparing to upgrade to the General- or Extra-class license.

For further information on these products, contact *Twin Oaks Associates, Route 5, Box 37, Knoxville IA 50138; (515)-842-6256.*

G.W. MORSE KEYS PEP/B CONVERSION MODULE

There are many reasons why it is more useful to be able to read peak envelope power rather than rms power on your output or incident power meter.

If you are running full legal power you need to know what your PEP is if you are to be sure you are within the 1500-Watt PEP limit. If you are running less than that it is still very useful to be able to adjust your drive or mike gain to the point where your final is just producing maximum peak power on speech. Any drive past that point is likely to result in some splatter and distortion (and wear and tear in your finals).

The movement and the needle of your forward power meter have too much inertia to be able to follow speech patterns, so the reading you normally get on speech as the needle swings up and down doesn't mean much. You can assume that if the needle bounces to about 50 Watts as you talk, you probably are producing about 100 Watts peak output. If you make a long "AHHHH" into the mike, it will probably read close to 100 Watts. But this is all guesswork. Most people seem to believe the needle should bounce to full output power as they talk—hence the large number of wide splattering signals there are around.

I have several power and swr meters built into the rig and antenna-matching units, so buying yet another meter just to be able to read PEP was not a welcome prospect. I saw an ad from Amateur Accessories (United Kingdom) for a conversion module that would convert any forward power meter to read PEP, so I sent for one. It came in a couple of weeks from G.W. Morse Keys in Wales.

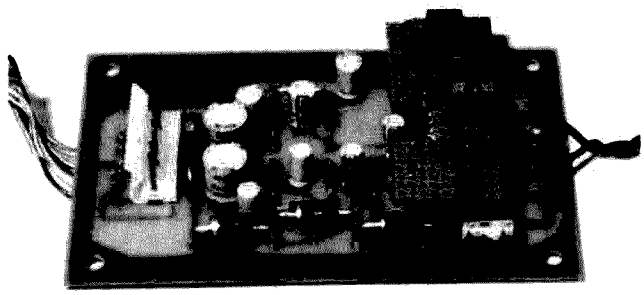
The whole thing is built on a printed circuit board 2.25 inches long x 1.25 inches wide and attaches with a single mounting screw. On the board is one integrated circuit and about 20 passive components. It requires a dc input of from 3 to 15 volts (the calibration is unaffected by voltage change) and takes about 1 milliamp. The manufacturer says that three heavy-duty AA cells in series would run it for about 9 month's continuous use, or about three years if switched off when the rig is not in use.

On the board, there are two calibration resistors in series which replace the movement of the existing meter. The voltage generated across these is applied to an amplifier which charges a capacitor through a diode. A second amplifier drives the meter. The total gain is unity, with 100% negative feedback.

The installation instructions are very easy to follow, and a diagram is supplied showing how to use a DPDT switch to remove the dc input and restore the meter to normal use. I did not bother to do this, as on key-down CW or on the "lock" position for adjusting the rig, rms power and PEP are the same (so I can meausre rms anyway) and I am taking 12 volts dc from the rig.

I installed the board in a Dentron MT-3000A antenna tuner. There is a space of about 5/8 inch below the chassis, shielded from stray rf, so one hole in the chassis for mounting and one in the back to take the dc cable took only a few minutes. I just cut the existing orange lead from switch to meter in the 3000A and soldered the leads from the PEP/B to the exposed ends. This makes it easy to restore the 3000A if I want to, by just joining the orange leads together again. This kind of technique saves a lot of notes in the manual. A screening board the same size as the PCB is supplied to protect the unit from stray rf if it is installed close to rf fields. I put it on just so that I would know where it is in the future.

The preset pots for calibration were set during manufacture at halfway, and this tuned out to be almost correct for the 200-microamp meter used in the 3000A. Calibration was quite smooth and easy (you just make it read the same on key-down as it did before you dabbled). When you talk, the needle rises quickly to the peak reading and stays there. When you cease talking it decays slowly, and one tap on the mike puts it right back to peak. As far as I can see it works just as advertised.



It costs 13.75 English pounds including postage and packing (US$17.00 at this time).

WA1GRC TPS-1

The WA1GRC TPS-1 is a twelve-volt-dc power-supply kit for the TAPR (Tucson Amateur Packet Radio) terminal node controller and compatibles. The TNC-1 comes equipped for ac operation only via a power transformer which attaches to the TNC circuit board with a seven-pin conector. The WA1GRC TPS-1 plugs into the TNC power connector in place of the plug from the power transformer. When an 11-to-14-volt-dc power source is applied to the TPS-1, the TNC operates as usual. Using 12 volts dc, the TNC draws about 0.75 Amps.

The WA1GRC TPS-1. The perfboard assembly is a modification which is explained in the text.

The main feature that separates this dc power converter from other systems devised to power the TNC from 12 volts is that no modifications to the TNC are required. No components have to be changed and no traces have to be cut. It just plugs in.

In fact, if the TNC's five-volt regulator is mounted on the TNC's circuit board, the transformer can be removed entirely. However, if the regulator is mounted off the circuit board and wired to the transformer's connecting plug, the transformer must remain, and the connecting plug from the transformer is plugged into a connector on the TPS-1. Alternately, the regulator wiring may be disconnected from the transformer plug and wired to another plug, which is then inserted into the TPS-1 connector.

Theory

The TPS-1 contains voltage-dropping, switching, and doubling circuits. The 11-to-14-volt-dc source is dropped through four diodes to provide about 10 volts dc. The dc source is also switched through a PNP/NPN transistor pair feeding the voltage-doubling circuits to provide the +25 volts and −25 volts (maximum) needed to run the RS-232 port on the TAPR TNC. Of course, the TPS-1 output voltages will vary slightly depending on the input voltage and load characteristics.

The TPS-1 output voltages are fed to the TAPR TNC's on-board regulators to provide the regulated power necessary to operate the board.

Assembly

The WA1GRC TPS-1 was designed by Gary Field WA1GRC and is sold by him as either a complete kit or a bare circuit board. I ordered the complete kit, and it arrived by first-class mail a few days later.

The instruction manual is a few pages long and contains brief assembly instructions, a board layout diagram, and a schematic. The assembly went smoothly, however. I did notice some inconveniences with the instruction manual which, if corrected, would decrease assembly time.

Assembly depends on both the board layout diagram and the component list (which are on different pages), and I found it bothersome to flip back and forth each time I soldered a few components to the board. The resistors are referred to by value, and their color code is not mentioned; thus I had to look up the color codes to make sure I was installing them correctly. The circuit board is single-sided and does not contain markings on the component side, so care must be taken to follow the layout diagram carefully. With such a small kit these are minor annoyances, however, it would be a good idea to examine the kit carefully before beginning construction.

The components were mounted and soldered on the board, the connector was wired, and the dc power cable was attached. I was finished with assembly. A quick voltage check matched the values given in the manual, so I was sure that everything went well during assembly.

Operation

Being able to run the TNC from 12 volts dc has many advantages. Mobile operation is possible, and it can be a lot of fun to operate packet while traveling. Many repeater sites where TNCs are kept for use as digipeaters have battery backup systems, and now the TNC can take advantage of them.

In my particular situation, I planned to operate packet mobile and portable using 12-volt gel cells. I took my TAPR TNC-1, TPS-1, TRS-80 Model 100 computer, and handie-talkie along with me on vacation this past summer and was looking forward to operating packet during the trip.

I say "was" because on the first day of vacation the packet system suddenly went dead. The TNC seemed to be operating normally, but I was not able to communicate with it through the computer! Later, at the hotel, I diagnosed the problem to be with the TPS-1. One of the switching transistors had shorted out (probably due to overheating caused by poor air circulation in my restricted mobile setup) and the TNC was not getting the +25 and −25 volts it needed to run the serial communications port. As soon as I located the nearest Radio Shack, I replaced the switching transistors with higher Wattage ones in a Darlington network (see photo) and was back on the air in short order. From this experience, I can inform you that it is important to keep the TPS-1 ventilated.

Conclusion

The WA1GRC TPS-1 12-volt power converter for the TAPR TNC-1 is very useful for those desiring to operate a portable or mobile packet station. It is a pleasure to be able to operate packet independently of the ac line.

The complete kit sells for twenty dollars and the bare board sells for ten dollars. For more information, or to order, contact Gary Field WA1GRC, 5 Pluff Avenue, North Reading MA 01864.

ABOVE AND BEYOND

Peter H. Putman KT2B
84 Burnham Road
Morris Plains NJ 07950

This month's column is prompted by several inquiries from local hams regarding the most cost-effective way to get a signal on the VHF bands. With times somewhat tight for the average amateur, this is an area of real concern for those who would like to upgrade their present HF capabilities or add more VHF/UHF bands to those already in service.

Consider the ham who purchases a working station for six meters with multimode radio, beam, and amplifier. Most likely he or she will have to shell out about $700–800 to come up with the 100-Watt station using a high-gain yagi. While this might not seem an unreasonable sum, it could very well be duplicated for each new bank added. A similar setup for 144 MHz, using a 100-Watt multimode and high-gain long-boom yagi, would come in about the same. 432 MHz would be similarly priced, and the newcomer quickly determines that the expense just isn't worth it.

But there is another solution: transverters. These magical little boxes allow the user to employ existing HF or VHF gear to access other VHF or UHF bands. If well designed, the performance is top-drawer, and all the best features of the existing HF or VHF transceiver are retained (i.e., scanning, memories, extra vfo's, SSB/CW filters, and so on).

"Well, where do I get one of these boxes?" *muses the prospective VHFer.* A glance through the current amateur mags turns up nothing—at least for those looking in the ads of the large retail outlets. All one sees is multimodes, multimodes, multimodes. Look again! There are at least four manufacturers of transverters engaged in actively selling their wares: Mutek, Ltd., and Microwave Modules, Ltd., of England, SSB Electronics of Germany, and Hamtronics of Rochester NY. There are other manufacturers of these devices, but their marketing efforts in this country are not on a level with these four. The European manufacturers sell their units as complete tested boxes—just plug 'em in and away you go. Hamtronics primarily markets their transverters as kits.

How does a transverter work? It's really quite simple: Incoming signals at the desired frequency are amplified by a MOS or GaAsFET device. These signals are then mixed with an on-board local oscillator (LO) to produce a difference frequency. This difference frequency is the LO frequency subtracted from the incoming desired VHF/UHF frequency, and it is called the i-f frequency—much as a superheterodyne receiver works. This i-f frequency is typically in the range of 28–144 MHz, depending on your needs and the converted band.

On transmit, the process works in reverse. The i-f frequency is mixed with the LO frequency to provide the desired transmit frequency. Again, MOSFETs are most commonly used in the mixer stages. Most transverters employ on-board rf power amplifiers to boost the converted transmit signal to about 10–15 Watts output. Newer models from some of the European manufacturers run more power (25 Watts), making them ideal for driving grounded-grid triode amplifiers, such as those using 8874 or 8877 tubes and even the new 3CX800 and 3CX1200 tubes.

"How much?" you ask. The answer is that you can purchase a transverter to take care of your particular band requirements for as low as $199. Now, that's a big difference from the price of the multimode mentioned before, and your performance may actually be better to boot. Consider this: A transverter is a linear device. What you put in, you get out (most of the time!). The only limitations are created by the performance of the individual devices used in the transverter, such as the MOS or GaAsFETs in the front end or the mixer devices. Still, it's an excellent way to add to your station complement without breaking the bank. And the additional savings could be towards a power amp or a mast-mounted preamp if desired.

Let's look at a typical transverter lineup. One very popular model is the Microwave Modules MMT 144-28. This unit takes 28-MHz signals and upconverts them to 144 MHz with 10 Watts of rf. Received signals at 144 MHz are downconverted to 28 MHz for reception on an HF receiver. First, transmitted signals at 28 MHz—typically 5–300 mW of drive—are fed into a dual-balanced mixer, typically employing 3N204- or 40822-type MOSFETs. Because this is a linear transverter, it doesn't matter what type of modulation is employed. The signal can be USB, LSB, AM, FM, and of course, CW. This low-level signal is mixed with the LO running at 116 MHz. The sum of these frequencies is amplified (144 MHz) in several stages, all of which are fairly tightly coupled and employ moderately high-Q tuning circuits to ensure adequate harmonic rejection. A power-amplified compartment then takes the low-level signal and amplifies in two stages to the rated 10–15 Watts output.

On receive, a 3N204 is typically used as a front-end amplifier. This device usually exhibits a noise figure (NF) at 144 MHz of about 2 dB, making it very acceptable for most VHF work. This signal is then mixed with the 116-MHz LO again and this time the difference of these frequencies (28 MHz) is amplified and fed back to the HF exciter. Tuning the band is accomplished by tuning the HF radio. In fact, these "black boxes," once tuned, can often be hidden away out of sight, as they usually require no further attention.

Similar units for 50, 432, and 1296 MHz also employ i-f frequencies of 144 MHz, to allow the person with the two-meter multimode to add another band. Again, the best features of the HF or VHF radio are retained by using transverters. Say you want to work some weak DX on 144 MHz, but a local QSO close to your frequency is causing QRM or splatter. You must switch in the SSB or CW filters on your HF rig! Try finding them on a multimode radio.

Here at KT2B, I use Microwave Modules on 144 MHz, 220 MHz, and 432 MHz—all driven by either an ICOM 740 or a Kenwood 430. On 1296, I employ an SSB Electronics LT23S transverter with an i-f of 144 MHz. Incidentally, the only multimode I use—a Kenwood TR-9000—is the "i-f" for the LT23S. This is primarily because of its scanning and fast stepped tuning, which are very useful when running up and down the band to find a QSO. Most of these units make provision for a separate antenna connection at the receiver input, allowing the use of an outboard preamp or switching through an external high-power amplifier if needed. I run mine straight through and use DPST antenna relays to bring external amplifiers in and out of the line. This is to allow QRP operation when desired.

What kind of radios can be used with a transverter? Models which have transverter provision already include Kenwood TS-520 series, 530, 820/830, 930/940, and 430. Also ICOM 730, 740, 735, 745, and 751. Many of the older Yaesu HF rigs, including the FT-101 series, made provision for an external transverter, and although the unit used tubes, the rf levels are sufficient for driving a modern-day transverter. The Collins KWM-380 has a transverter connection, and I can tell you that working 50-MHz sporadic E on a KWM-380 with a Mutek 50-MHz transverter is an experience you will not believe!

What if your radio doesn't have a transverter port? No problem. The best bet is to locate the output from the low-level rf stages before they go to the final amplifier assembly. Simply breaking this line and bringing it to a rear-panel connector, then running another line from a second connector back to the final gives you the desired connection. I employ this method on my ICOM 740 to obtain increased drive for the MMT-series modules. Jumpering the two connectors restores full HF transceive operation. On receive, use the normal antenna connector on your HF rig and connect to the 28-MHz i-f output jack on the particular transverter.

If your HF or VHF exciter runs 10 Watts or less, many of the transverter makers have 15-dB pads to drop the drive level low enough for the transmit mixer. Or, you can make one yourself out of six 2-Watt 100-Ohm carbon resistors. Connect them as shown in Fig. 1. This will dissipate most of the rf, leaving a small amount for the mixers to work with. The attenuator is generally employed with 144-MHz multimodes when converting to 50, 432, or 1296 MHz. Usually there is sufficient gain in the receiver i-f mixer to overcome the losses of this pad, especially when used in the transceive mode.

Other HF radios that could be used with this attenuator include the Ten-Tec Argonaut series, the older TS-130V, and almost any ICOM in the low-power position. Note also that all of the transverters currently available have built-in sensitivity controls to allow for a range of about 5–300 mW of drive, so you must not exceed 300 mW. When in doubt, use a pad. A 1-Watt signal padded down by 15 dB translates into about 50 mW of drive—more than adequate.

Newer modules promise increased band coverage. Microwave Modules has announced the MMT 144-28R, with GaAsFET front end and 25 Watts output power. In addition, there are two additional LO frequencies incorporated into the transverter to allow for simplex and ±600-kHz operation on FM. As presently configured, the coverage is only 144–146 MHz (the European two-meter band), but discussions with the US importer reveal plans to add a fourth LO to switch coverage up to 148 MHz to allow repeater use. Don't have a two-meter base-station rig for FM yet? One of the new transverters and the FM module for your HF radio will do the trick.

The key here is to get the maximum use from your already-purchased HF or VHF multimode radios. ICOM has announced the IC-1271 multimode for 1296 MHz, but it carries a retail price tag of *almost $1000!* For half the cost, a transverter could be bought that would do much the same thing.

An interesting development is the production of a 220-MHz transverter by SSB Electronics of Germany for the US market. This is not an allocation in Europe, so such a device is a bit of a gamble on the part of the folks from Iserlohn! Of course, Transverters Unlimited of Canada already markets such a device, based on the Microwave Modules design. For those who prefer to roll their own, Hamtronics of Rochester NY markets a full line of transverters for 50, 144, 220, and 432 MHz including a model that permits 28–30-MHz

operation from a 144-MHz i-f! The units are sold separately as a transmit converter and receive converter. A typical VHF transverter would cost about $120, based on the latest ads.

I often hear rumors that the big three in Japan (ICOM, Kenwood, and Yaesu) are planning to come out with transverters for the US market. These rumors would tend to be substantiated by the "transverter" accessory sockets and connectors found on many of these rigs. As of yet, I haven't seen a single one, but I can guarantee that if sales of the European and North American transverters increase by a sizeable amount, we'll have plenty of products to choose from in short order. Incidentally, I mentioned the Yaesu transverters for the FT-101 series; Kenwood also marketed transverters for 144 and 50 MHz for use with the TS-520S series. They make serviceable units if you can locate them at flea markets and hamfests. But for now, nothing from Japan.

If you feel so inclined, you can obtain a couple of B&W coax switches and select up to six transverters using 28-MHz i-fs! This is similar to a system I employ here, where 3 different bands are selected independently for the TS-430S. It makes rapid QSYing for prearranged schedules a real pleasure. And as was mentioned earlier, you can hide the boxes away if needed, to save on shelf space. All they require is 13.8 volts dc and some sort of keying line, unless you use the internal rf-sensed keying that many provide. The SSB Electronics LT23S provides an on-board attenuator to allow direct drive from a 10-Watt multimode 144-MHz transceiver.

What's coming down the pike? High-performance transverters for 50 through 2304 MHz, using GaAsFETs and diode mixers to improve dynamic range and noise figure. Transverters will be available for the new 902-MHz band shortly as well. Bandswitched crystal LOs will allow full coverage of the desired band, and of course, all-mode operation is possible on any band. I'll be reviewing some of these new models as they appear on the US shores. Look for reviews of the MMT 144-28R shortly.

Mailbox Department

This month we hear from Australia in the person of Roger Harrison VK2ZTB who is the editor of *Australian Electronics Monthly*, a slick general-interest publication not unlike *Popular Electronics* here. Roger tells of his interest in forecasting sporadic-E propagation on six meters and two meters and is very interested in the study published by Sid Lieberman WA2FXB which I mentioned several months ago. It would seem that there has been a surge in interest in this topic down under, and Roger has many clever observations pertaining to sporadic-E propagation. One in particular pertains to antenna stacking when working "scatter waves" (as he refers to them). Based on observations he and Rod VK2BQJ made, the optimum performance obtained with stacked 50-MHz yagis—working primarily sporadic E—was with the two beams 10 feet apart, or about ½ wavelength. Roger further observes that "antennas stacked one wavelength apart can often act to cancel scatter signals much of the time, as stacking for maximum plane-wave gain results in gain degradation for scatter signals."

Roger publishes the *6-UP* newsletter which contains much useful information about Aussie activities on the VHF and UHF bands, as well as several practical circuits for construction. A design for a five-element 50-MHz beam is also featured. It makes for good reading and I hope Roger will continue to forward issues from time to time. One last story which caught my eye was the attempt by Don Richards VK2BXN to work auroral scatter from the Antarctic during a scientific expedition. Apparently Don was to pursue a course that would take him under the auroral curtain, so he had the unique experience of trying to work both conventional back-scatter and front-scatter! Although Don was equipped with 100 Watts and a single yagi, he made no contacts with stations back in Tasmania and southern Australia but did hear faint CW signals at one of the appointed times.

Incidentally, the ship on which Don made his voyage was the *Dick Smith Explorer*, which I assume was the ship destined to tow an iceberg into Sydney Harbor some years back. What will those folks from VK-land think of next?

Until next month, see you Above and Beyond.

LETTERS

VITALLY IMPORTANT

I must strongly disagree with the opinion expressed by William Itter N9EWA in the November, 1985, "Letters" column. Though it is not the main thrust of his letter, Itter implies that the Novice-class license is essentially worthless, not only in its technical expertise, but in its privileges.

From personal experience I can say that one reason many people shy away from amateur radio is their fear of a long and involved test of radio theory. The Novice license serves as a relatively painless entry point to expose the newcomer to the exciting possibilities of amateur radio. Since the technical requirements of the Novice license are slight, the Novice should not expect to earn a wealth of privileges. By design, the privileges *are* limited. The idea is that once the Novice has had a taste of what ham radio is and has discovered how much more there is to do in this incredibly flexible hobby, he or she will be motivated to stay involved long enough to upgrade.

I agree that "an increase in our ranks is not going to come from either fewer restrictions or greater privileges," but the question of privileges is essentially irrelevant to enticing the newcomer to amateur radio. However, since amateur radio is continually changing, the privileges granted Novices should be periodically reviewed.

Another point Mr. Itter makes concerns the involvement of young children with computers. Most kids who become interested in ham radio get their start through the Novice license. Children as young as five have passed the exam. I wonder how many children would be turned away from ham radio by the elimination of the Novice license? How many five-year-olds do you know who could pass the Technician test?

Various radio journals have expressed their concern about the rising average age of the ham population. Do we want to aggravate this problem? We must realize that there is no exam to take before you use a computer. Computers are fascinating to children, who are exposed to them both at home and at school. But amateur radio is just as fascinating! Our problem is that we lack exposure. We need to work together to resolve this problem.

So, if we want lasting growth, maybe we should organize and pressure ham manufacturers to donate or discount radio gear to schools and youth groups. Of course, this would be pointless without the support of the amateur-radio community to develop and run the programs and clubs that would be needed. What good is a donated radio if it sits in a closet because nobody knows how to use it? Further, we must not elevate the entrance-level exam beyond the capabilities of young children. The Novice license is vitally important to the hobby.

J. Bruce Tinkler N9FJQ
Barrington IL

FINE WORK!

Regarding the Nuller Bridge by Bill Vissers K4KI ("Wheatstones Are Not Crackers!", September, 1985): Fine work! The little gadget works perfectly and costs only a few dollars to build. I've made three of them so far, the last one combined with a 50-Ohm, 100-Watt dummy load. The bridge is excellent, as there is *no* rf being radiated while resonating the antenna or tuning the transmitter.

Barrie Coates VE7AQK
Peachland BC

GOOD OLD DAYS

About your answer to KK2W's letter in the November, 1985, issue. It's interesting that you and he have apparently divergent views about the Novice license and privileges—and that neither of you is right.

Want to know what's right? Maybe I'll tell you, but first I'll tell you the way things were in 1950. The Novice program was still new. As I recall, there were three license levels, four if you count the Technicians: Novice, Technician, General, and Advanced. (I'm omitting the Conditional license.) The Novice license was good for one year and was nonrenewable, the others good for five years and renewable.

You couldn't be a Novice for more than a year, and you couldn't be an Advanced until you had been a General for at least a year. I don't think there was a 20-wpm Extra ticket until 1951 or 1952. Novices had only CW privileges on 80m and maybe phone on 2m. The 15m band wasn't available to anyone yet. Generals had all bands for CW and phone on 10m, while Advanced licensees got it all.

What in Maxim's name is wrong with that system? Nothing that I can see. The Novices had incentive and the Generals had apprenticeship. I think that all the talk about incentive licensing wouldn't be necessary if that licensing structure had been maintained.

A. J. Massa W5VSR
New Orleans LA

One of the worst things the FCC has ever done to ham radio was when they made the Novice license renewable. How many "career Novices" do you think are in the ranks now? And how many will there be after the "super Novice" ticket is available? Seems to me that the renewable Novice license is an invitation to stagnation.—KW1O.

59 – 20 dB

"Improve Your Audio Report" (November, 1985) is good advice. Jim W2OZH has done an outstanding job analyzing and documenting the need for good audio and a better reporting system. His message is 599 (QRI 10).

However, amateur radio is still a process of establishing communications links in a variety of modes and media, not just high-power audio on the rag-chewer's bands. If RST is out of date, then so are Q signals. Three digits of RST are bad enough, let alone 5 digits of QRI! Let's leave RST to QRP and let's get good audio by the use of technology (better equipment, microphones, and level control).

Since when is hi-fi audio needed on ham radio? Better we concentrate on what to say and how to say it. Most of our commercial equipment will get the message through QRM and QRN.

When I'm on phone I can say, "Your audio is clear and understandable and pleasant to hear. How do I sound?" And you can bet he'll tell me *in detail* what is wrong with my audio! Then there are those contests where everyone is 59 unless you can't hear them.

Bravo, Jim, but I'll wait for some other suggestion that can beat your QRI.

Staff Stafford NJ8F
Delaware OH

Q & A

December, 1985's "QRX" column talks about "The Final Exam" series by Dick Bash. Now that the ARRL includes FCC questions *and* answers in their study guides, I hope that you will refer to the League as "infamous" as well or you will be guilty of the worst kind of discrimination!

Clyde Grubbs WBØTYR
Jamestown ND

Dick Bash asked hams to write down questions and answers from the exam as they walked out of the testing room; his "study guides" were simply verbatim copies of the FCC exam. In fact, Dick advised examinees to ignore the warning printed on their test—the warning that said, "An attempt...to copy or divulge examination questions is a violation of FCC rules for which penalties are provided."

Under the new testing structure, all of the questions for each element are in the public domain. Since there are several hundred potential questions for each exam, it's virtually impossible to memorize enough material to pass a test. The League (and others) publishes study guides with answers to help an applicant understand the information he or she needs to upgrade; this is totally different from the verbatim regurgitation of answers by Bash's graduates.

Clyde, you mentioned that you teach a Novice class every fall. Let me ask you this: Do your students pass their exams because they understand the subject or because they've memorized twenty answers?—KW1O.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Well, I do get taken aback once in a while, and a phone call I recently received did just that. Frank Fox WA6KGD telephoned me to indicate that the news of the death of Super-RATT was a bit premature. It seems that he has assumed the distribution of this program, written for the Apple II, II+, IIe, and IIc. It requires 48K of RAM and one disk drive and interfaces with an outboard terminal unit and AFSK generator using TTL-level signals. He tells me that the program is available for $79 from him at 186 Isabella Street, Hayward, California 94544. If you like, you may reach him by telephone at (415)-538-7832 after 5:00 pm California time, and on weekends. Do I have to remind you to tell him you saw it here? I thought not!

Now, the planned RTTY computer this month is the Radio Shack Color Computer®, also known as the TRS-80C or the CoCo. This little gem of a computer has caught the eye of many a ham, both for its economy (I have seen the 16K model selling for less than $90 at my local store) and for the ease of programming the 6809 CPU.

Unfortunately, this ease of use, economy, and convenience is not matched with a plethora of RTTY programs. In fact, only two commercial programs were mentioned in all of your input.

Kantronics, which produces a version of their Hamsoft program for most of the popular microcomputers, markets a ROM-cartridge version for the CoCo. One of you wrote with some observations: "Operationally, it requires TTL signals, not RS-232. I had no trouble connecting it to my [terminal unit] and [transceiver]. It has a built-in parallel printer port, but no documentation on using it outside of the program. [The] documentation is only adequate; no schematic [is supplied]. Supports CW from 5 to 99 wpm, RTTY speeds from 60 through 132, ASCII from 110 to 300 baud. There are a number of useful configuration/operating options, 10 loadable/editable message buffers, and a type-ahead buffer. It runs with a 4-way split screen on a normal 32×16 CoCo screen. On the good side, it does work. I found no bugs, per se. The above features are nice.

"Many 'little things,' though, add up to a poor implementation of a good idea. The time-of-day clock loses about 1 minute in 8 hours. The control functions on the keyboard are easy to remember, but impossible to type one-handed (like <CLEAR><S>). There is no 'quick-load' message buffer for use during QSOs. You cannot clear the type-ahead buffer. The system is much too susceptible to noise. Even low-level QRN makes the CW-receive function useless. RTTY seems a little better, but still less noise immune than seems right for a CoCo. The receive CW speed must be calculated only on dit time; sending at the receive speed is almost always too fast. The CW algorithm lacks stability. With ORN it will jump from 18 to 88 wpm in one character time—one QRN 'pop' wipes out two characters, usually.

"I needed a program, so I am glad I have it, but I know I'll be writing one of my own as soon as I have the time." Ah, yes, the time; don't we all wish we had it!

Contrast that firmware product with another one that is far and away the most popular choice, a program marketed by our old friend Clay Abrams called NEWRTYCW. This program, written by Mike Meeks WA4VEF, is a machine-language program which features transceive operation in CW, RTTY, and ASCII. Four "station buffers" are maintained, each one 254 bytes in length. These can be loaded at the beginning of a session. There are two large buffers, a "keyboard" buffer and a "receive" buffer, both of which are 12K in a 32K CoCo. These buffers can be typed into or printed out on the station printer, as the need dictates. Full ranges of CW and RTTY speeds are supported, and the program interfaces through the "bit-banger" RS-232 port on the back of the CoCo.

This versatile piece of software is available from Clay Abrams Software, 1758 Comstock Lane, San Jose, California 95124. While I don't have a current price, I am sure that Clay would be glad to help you.

Now, there are a few problems. Unlike every other computer program mentioned here to date, this one seems to cause the hacker instinct to emerge. NEWRTYCW is supplied on tape only, and Clay tells me that there are no plans to release a disk version. Although transferring the tape program to disk does not allow disk I/O or other disk-based advantages, it does promote faster, more convenient loading with less chance of a load error. To that end, many—no, most of you—who wrote with your praises of the program included your own scheme for transferring this self-booting copy-protected program to disk.

I wrote to Clay and asked him if he minded my publishing such a scheme, and he said that he did not mind, but that he could not, of course, endorse or support such a patched program. So, if you have purchased a copy of NEWRTYCW, read on.

Of all the schemes I looked at, the best is to offset-load the program, defeating the auto-boot, and then move it back where it belongs for use. The most elegant of these is shown in Program listing 1. Submitted by Rick Koch WB1BRR of Derry, New Hampshire, it is a short loader routine appended to the front of NEWRTYCW. The modified program may be SAVEMed to disk, from which it can be LOADMed and EXECed without problem.

```
2077    1A 50     ORCC #$50
2079    8E 208E   LDX  #$208E
207C  108E 0109   LDY  #$0109
2080    EC 81     LDD  X++
2082    ED A1     STD  Y++
2084    8C 3F04   CMPX #$3F04
2087    23 F7     BLS  $2080
2089    1C AF     ANDC #$AF
208B    7E 0109   JMP  $0109
```

Program listing 1.

While Program listing 1 is the assembly version of the loader, a more practical solution for many users will be Program listing 2. This Basic program will, when run, put the loader in memory at the correct location. To use this scheme, enter the program and save it to disk as PATCH.BAS. Then put the tape with NEWRTYCW in the recorder. Type RUN"PATCH and when the OK prompt comes back, type CLOADM "NEWRTYCW",&H1F85. The tape will load, and you will get another OK. At that point, type SAVEM"RTTY",&H2077, &H3F04,&H2077 and you will be all set. Now, to go onto RTTY, just type LOADM"RTTY and EXEC the program.

Program listing 2.

My thanks to Rick Koch, Ernie Marquez KP4EIH, Rob Rochelle WA4DAZ, George Fundis KD4RC, Calvin McCarthy VE3LMP, Fred Wood WB3JKC, Gary Bender, and, of course, Clay Abrams K6AEP, along with the many others who expressed an interest in RTTY on the CoCo.

The shack of the month this month is a bit unusual. Instead of showing a shack with a ham sitting there, this is really a ham *in* his shack! Clay Abrams sent along the photo of his new computer shack, with quite a display on the screen! I'll say this, Clay, it is different!

The Pittsburg (Kansas) Repeater Organization, Inc., graced my mailbox with their bulletin, *The Procrastinator*, this month. Looks like an active group out there, with a repeater on 146.94 MHz and all kinds of functions. Of RTTY note in this bulletin is another version of the increasingly popular AFSK generator based on the XR-2206 function generator. Hams in the Pittsburg area may wish to listen to .34/.94, or contact PRO, Inc., at Box 1303, Pittsburg, Kansas 66762.

Is packet a part of RTTY, or is it a separate interest? I ask because I have been checking into HAMNET on CompuServe lately, and much, if not all, of the discussion there in the RTTY/AMTOR/Packet section is on the growing topic of packet radio. A buddy of mine has demonstrated just what can be done with packet, and I am impressed. Other than a short tutorial presented here a few months back, though, I have not covered much in that camp. Let me know what you think, yea or nay, for future coverage of this new topic.

Shack of the month: K6AEP.

Interested in copying commercial RTTY stations? Joerg Klingenfuss has brought out the fourth edition of his *Guide to Utility Stations* which is about ten percent bigger than last year's! He's even including VLF and LF stations now, plus meteorological FAX stations, and more. The guide sells for DM60 (you're on your own for conversion to dollars) and is available from Klingenfuss Publications, Hagenloher Str. 14, D-7400 Tuebingen, Federal Republic of Germany. You know whose name to drop, right?

A few months ago I mentioned the new CoCo keyboard that was appearing in stores. Selling for $4.95, this little wonder sports four keys not on the original CoCo keyboard: CTRL, ALT, F1, and F2. I wondered out loud about some software to put these keys to use. Well, another old friend, Bob Rosen, mentions that Spectrum Projects, PO Box 21272, 93-15 86th Drive, Woodhaven NY 11421, is selling a program that allows these four keys to add a 9600-baud POKE, text-screen dump, LIST command, and cold start. The CoCo keyboard enhancer is supplied on disk for $14.95.

Response on the reprint series has been most gratifying, with many of you passing along individual stories of how some of the information supplied has helped you to get on RTTY. If you would like a list of reprints available, each of which is extracted and updated from material published in this column over the past nine years, send a self-addressed, stamped envelope to me at the above address. Each reprint is $2.00, in case you are curious, but send for the list first, OK?

Don't be shy about including other comments or questions when you ask for the reprint list. I read every one and try to answer as quickly as I can. Quite a few of you have found that answers to questions submitted on CompuServe have appeared on the same day the question was sent! Mail to the above address, or EasyPlex to ppn 75036,2501. I look forward to your comments, questions, and information.

Many of your questions about specific pieces of commercial RTTY gear have been forwarded to the respective manufacturers of the equipment, but the responses have been slow in coming. I don't know if any of them read this column, which clearly is one of the longest (*the* longest?) running RTTY columns, but feedback from them is nil, folks. I can only print what information I receive, so if I am not saying much about a converter, node controller, computer, or whatever, it is *not* because I am biased or ignoring that line; it's because I have no information.

Information to share? Well, there certainly will be some next month. I know because I see some of it sitting on the clipboard already. If you want to see what it is going to be, don't miss the next edition of "RTTY Loop."

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" x 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

Help! I've been searching everywhere for information on how to do a "fast-scan" modification to my ICOM IC-02AT. Can anybody help me?

Michael Gasser KA8WPC
7630 Reitz Rd. #144A
Perrysburg OH 43551

I am looking for a Kenwood DG-5 digital display for my TS-520SE.

Mike Weir
310 Niska Rd. #104
Downsview, Ontario

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

VERMONT QSO PARTY
Starts: 0001 UTC February 1
Ends: 2400 UTC February 2

Sponsored by the Central Vermont Amateur Radio Club (W1BD). Each station may be contacted once on each band and mode (CW, phone, RTTY). CW and RTTY contacts must be in the CW and RTTY subbands. Duplicate and repeater contacts are invalid.

EXCHANGE:

RS(T) and state, province, ARRL country, or two-letter designator for VT county (AD, BN, CA, CN, EX, FN, GI, LA, OG, OL, RU, WA, WM, WR).

FREQUENCIES:

Phone—3.910, 7.230, 14.260, 14.320, 21.360, 28.570, 50.110, 144.2. CW—3.540, 3.720, 7.040, 7.120, 14.040, 21.040, 21.140, 28.040. RTTY—3.620 and 90 kHz from lower edge of other RTTY subbands.

SCORING:

Score one point per phone contact, 5 points per CW or RTTY contact. VT stations multiply QSO points by sum of VT counties, states, Canadian provinces, and ARRL countries (exclude US/Canada). Others multiply QSO points by the number of VT counties (14 maximum). Add 20 bonus points for working W1BD.

AWARDS:

For non-VT stations, certificate to highest-scoring station in each state, province, and country. Certificates will be given to each VT station submitting a log. A plaque will go to the highest-scoring VT station. W/VT Award given to stations working 13 of Vermont's 14 counties.

ENTRIES:

Send SASE for official log and score sheets. Send logs/facsimiles, name, class of license, and address—not later than March 1, 1986, to: D. Loverin WA1PDN, 50 Liberty Street, Montpelier VT 05602. Include an SASE for a copy of the results.

NORTH CAROLINA QSO PARTY
Starts: 1400 UTC February 1
Ends: 0500 UTC February 2

The North Carolina QSO Party is sponsored by the Alamance ARC. Work stations once per band and mode (CW and phone). Work mobiles as they change counties.

EXCHANGE:

Signal report and ARRL section (county for NC stations).

FREQUENCIES:

CW—3.525, 3.725, 7.025, 7.125, 14.025, 21.025, 21.125. Phone—3.890, 7.290, 14.290, 21.275.

SCORING:

Count one point per phone QSO; two points per CW QSO. NC stations multiply by total NC counties worked. NC mobiles may add 500 points to their score for each county outside their home county in which they make 15 QSOs.

AWARDS:

Certificates will be awarded to the highest-scoring non-NC entry, highest-scoring NC stationary entry, and highest-scoring NC mobile entry.

ENTRIES:

Mail logs by March 1, 1986, to: North Carolina QSO Party, c/o K4EG, PO Box 3064, Burlington NC 27215.

NEW HAMPSHIRE QSO PARTY
1900 UTC February 1 to 0700 UTC February 2
1400 UTC February 2 to 0200 UTC February 3

Sponsored by the NH Amateur Radio Association. Stations may be worked once per band and mode. NH stations may work each other.

EXCHANGE:

Send RS(T) and ARRL section/country or NH county as appropriate.

FREQUENCIES:

Phone—1.875, 3.975, 7.235, 14.280, 21.380, 28.580, 50.115, 144.205. CW—1.810, 3.555, 7.055, 14.055, 21.055, 28.055. Novice—3.730, 7.130, 21.130, 28.130.

SCORING:

NH stations score 1 point per QSO, multiplied by the sum of NH counties, ARRL sections, and DXCC countries worked (excluding NH, US, Canada, and DXCC countries within ARRL sections). Others score 5 points per NH QSO times the number of NH counties worked (10 maximum). In addition, all stations count 20 bonus points each for working the following NHARA member club stations: N1BYQ, WB1CAG, WB1FFZ, KB1HJ, W1OC, K1RD, W1WQM, and K0UNJ for a maximum of 160 bonus points.

AWARDS:

Certificates to highest scorer with a minimum of 5 QSOs in each NH county, ARRL section, and DXCC country. Plaque to the highest scorer in NH courtesy of Concord Brasspounders. A Worked All NH Award, sponsored by W1JB, will go to participants who work all 10 NH counties.

ENTRIES:

Send your entry no later than March 25, 1986, to Mount Moriah Repeater Association, c/o Bud Valcourt N1BYQ, 19 Teague Drive, Salem NH 03079. Include a large SASE for a copy of the results.

YL-ISSB QSO PARTY—PHONE
Starts: 0001 UTC February 8
Ends: 2359 UTC February 9

The QSO Party is open to all but emphasis is on member participation and member-to-member contacts. Operating categories include: single operator, DX-W/K partners, and YL-OM teams. All US General phone bands will be used. VHF and UHF may be used but all contacts must be direct and not through repeaters. Nets are not allowed!

EXCHANGE:

Signal report, state/province or country, name, ISSB number (if member), and DX-W/K partner's call. If no partner, leave blank. If nonmember, send "no number."

FREQUENCIES:

On HF use the USA General-class band portions. On 20 meters be aware of the nets on 14.313, 14.336, etc. Stay away from 14.332; leave it open for DX members trying to make contacts. Check 80 and 40 meters on the hour. VHF and UHF use simplex only.

SCORING:

Score 3 points for each two-way member contact on own continent, 6 points if different continent. Nonmember contacts count *one* point. Only member-station contacts count for multipliers. Multipliers are each US, VK, ZL, and VE state or province and each DX country. Also, each DX-W/K or YL-OM team contacted, but only once for each team. When DX-W/K partners contact each other it counts as a double multiplier. If your total dc input power is 250 Watts or less during the entire QSO Party, then count an additional power multiplier of *two*. Final score is sum of QSO points times the total multiplier.

AWARDS:

Special certificates will be awarded to the overall winners of each category. Regular certificates for DX country, US state, and Canadian province winners.

ARA SQUELCH TAIL

NEWSLETTER OF THE MONTH

February's award-winning publication is the Arizona Repeater Association's *Squelch Tail*, edited by Betty Kaiser WA6HRX. The *Tail* is mechanically one of the best newsletters we have seen in a long time. Of course, good looks aren't the only thing that the *Squelch Tail* has going for it! Betty and her staff fill its pages with interesting news clips and feature articles, drawing from sources such as *Westlink* and the *ARRL Letter*.

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to 73 Magazine, Editorial Offices, 80 Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

EGE Has Reduced Prices

ICOM DAY FEB 22

Call Toll Free for Orders & Quotes: 800-336-4799

In Virginia: 800-572-4201

ENTRIES:

Logs must show usual contact info plus ISSB numbers and QTHs. Mail entries before April 30, 1986, to Bill Early WA9AEA, PO Box 401, McHenry IL 60050-0401.

DUTCH PACC CONTEST
Starts: 1200 UTC February 8
Ends: 1200 UTC February 9

Use all bands, 160 through 10 meters, CW and SSB. No crossmode operations are allowed and please use the band sections according to the IARU recommendations. Each station may be worked only once per band regardless of mode. Operating categories include single operator, multi-operator, and SWL.

EXCHANGE:

RS(T) plus sequential QSO serial number starting with 001. Dutch stations will send their two-letter province abbreviation instead of a QSO number: GR, FR, DR, OV, GD, UT, YP, NH, ZH, ZL, NB, and LB.

SCORING:

Each QSO with PA, PB, or PI counts one point. Multiply QSO points by the number of provinces worked on each band (6 × 12 = 72 maximum). SWLs count one point per Dutch station heard and multiply by provinces heard on each band (72 maximum).

ENTRIES:

As usual, a score calculation is required. Please use a multiplier column and insert multipliers only if they are new. A log must be signed for observation of the contest rules. SWL logs must contain code groups given by the Dutch station and the foreign station worked. Send logs not later than March 31, 1986, to: F. Th. Oosthoek PA0INA, PO Box 499, 4600 AL Bergen op Zoom, Netherlands.

A certificate will be awarded to each country winner in each category along with the second- and third-place stations, provided there is sufficient participation in that country. Certificates will also go to winners in each call district of JA, LU, PY, UA9/0, VE/VO, VK, W, ZL, and ZS.

ARRL INTERNATIONAL DX CONTEST
CW
Starts: 0000 UTC February 15
Ends: 2400 UTC February 16
Phone
Starts: 0000 UTC March 1
Ends: 2400 UTC March 2

The annual DX contest for all DX hunters is sponsored by the ARRL and open to all amateurs worldwide. W/VE amateurs are to work as many amateur stations in as many DXCC countries as possible on 1.8 to 30 MHz, excluding the 10-MHz band. Foreign amateurs are to work as many W/VE stations in as many states and provinces as possible. Check January, 1986, *QST* for any last-minute rule changes. Operating categories include:

(A) Single operator—one person performs all operating and logging functions. Spotter nets are not allowed and only one transmitted signal may be used at any given time. Within the single-operator category participants may compete within allband or single-band categories as well. Single-band entrants who make contacts on other bands should submit logs for checking purposes.

(B) Multi-operator—more than one person operates, checks for duplicates, logs, etc. Within this category entrants may compete within single-transmitter, two-transmitter, or unlimited-transmitter categories. Single transmitter implies only one transmitted signal at any given time and once station has begun operation on a given band, it must remain on that band for at least 10 minutes. Listening time counts as operating time. Multi-op single-transmitter stations must keep a single, chronological log for the entire contest period.

Two-transmitter multi-op entrants are limited to only two transmitted signals at any given time. Again, each station must stay on a given band for a minimum of 10 minutes. Both transmitters may work any and all stations; the second transmitter is not limited to only working new multipliers. Each of the transmitters must keep a separate log.

With an unlimited number of transmitters for multi-op entrants, only one transmitted signal per band is permitted at any given time. Separate, chronological logs must be kept for each band.

(C) QRP—10 Watts input or less (or 5 Watts output or less), single operator, allband only.

Each operator must observe the limitations of his license at all times. Your callsign must indicate your DXCC country station location. One operator may not use more than one callsign from any given location during the contest period. The same station may be worked only once per band, no crossmode, crossband, or repeater contacts. Aeronautical- and maritime-mobile stations outside the US and Canada may not be worked for QSO or multiplier credits by W/VE stations. All transmitters and receivers must be located within a 500-meter-diameter circle, excluding directly connected antennas. This prohibits the use of remote receiving installations. However, multi-operator stations may use spotting nets for multiplier hunting only.

EXCHANGE:

W/VE stations send RS(T) and state or province. DX stations send RS(T) and power as three-digit number approximating transmitted input power.

SCORING:

All stations count 3 points per valid QSO. W/VEs multiply QSO points by sum of DXCC countries (except US and Canada) worked per band. DX stations multiply QSO points by number of US states (except KH6/KL7) and District of Columbia (DC), VE1-7, VO, and VE8/VY1 worked per band (58 maximum per band).

AWARDS:

Plaques awarded to top W/VE scorer in each entry category, top scorer in the single-operator allband category worldwide and on each continent, worldwide leaders in the single-operator single-band, QRP, multi-op single-transmitter, multi-op two-transmitter, and multi-op unlimited categories, plus additional special plaques as sponsored.

Certificates will be awarded to top single-operator allband entries from each country and ARRL section; top single-band entries in each US call area and each country; top multi-op entries in each country, US call area, and in Canada. Additional single-band and multi-op certificates will be awarded if significant effort or competition is displayed. Also, DX entrants making more than 500 QSOs on either mode will receive certificates. ARRL-affiliated clubs also compete for gavels on three levels: unlimited, medium, and local clubs.

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, 80 Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

ENTRIES:

All entrants are encouraged to use official forms available from the ARRL to report contest results. Logs must indicate times in UTC, bands, calls, and complete exchanges. Multipliers should be clearly marked in the log the first time worked. Entries with more than 500 QSOs total must include cross-check sheets (dupe sheets). All operators of multi-op stations must be listed.

Entries must be postmarked within 30 days of the last contest weekend, otherwise they will be classified as check logs: no extensions, no exceptions. All stations are requested to send their entries in as early as possible. Each entrant agrees to be bound by the provisions of the ARRL rules, licensing authority, etc., and the decisions of the ARRL Awards Committee are final. Usual ARRL disqualification rules apply. Address entries and forms requests to ARRL Headquarters, 225 Main Street, Newington CT 06111.

RTTY WORLD CHAMPIONSHIP
0000-2400 UTC February 22

Sponsored by *The RTTY Journal* and *73* Magazine. The same station may be worked once on each band. Crossmode contacts do not count. Single-operator stations may work 16 hours maximum, while multi-operator stations may operate the entire 24-hour period. Off times are no less than 30 minutes each and must be noted in your log(s).

Operator classes are (a) single operator, single transmitter, and (b) multi-operator, single transmitter. Entry categories are (a) single band, and (b) allband, 10-80 meters.

EXCHANGE:

Stations within the 48 continental US states and Canada must transmit RST, and state, province/territory. All others must transmit RST and consecutive contact number.

SCORING:

5 QSO points for contacts with W/VE stations located within the continental US and Canada. 10 QSO points for all other contacts. 1 multiplier point will be awarded for each of the 48 continental US states (a District of Columbia contact may be substituted for a state of Maryland multiplier), Canadian provinces/territories, and DX countries worked on each band (excluding US and Canada). Total QSO points times total multipliers equals claimed score.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts, Canadian provinces/territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 25 QSOs must be worked to be eligible for awards.

ENTRIES:

Entries must include a separate log for each band, a dupe sheet, a summary sheet, a multiplier checklist, and a list of equipment used. Contestants are asked to send an SASE to the contest address for official forms. All entries must be postmarked no later than March 22, 1986, and sent to RTTY World Championship, c/o *The RTTY Journal* 1155 Arden Drive, Encinitas CA 92024.

Operating in excess of legal power, manipulating scores or times, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

ALABAMA QSO PARTY
Starts: 1600 UTC February 22
Ends: 2300 UTC February 23

Sponsored by the Birmingham Amateur Radio Club. Work stations once per band and mode. Work mobiles and portables again as they change counties.

EXCHANGE:

Signal report and QTH (county for Alabama stations; state, province, or country for others).

FREQUENCIES:

CW—1.810, 3.550, 7.050, 14.050, 21.050, 28.050. Phone—3.900, 7.260, 14.300, 21.360, 28.600, 50.110, 144.20, 146.52. Novice—10 kHz up from the low end.

SCORING:

Count 2 points per phone QSO, 3 points per CW QSO. Alabama stations multiply by total states, provinces, Alabama counties, and countries. All others multiply by total Alabama counties (67 maximum). Multiply scores by 1.5 for 200 Watts or less and multiply by 1.5 for noncommercial power (mobiles excluded from noncommercial multiplier). Mobiles add 500 bonus points for each county from which 10 or more QSOs are made.

AWARDS:

Trophies will be awarded to the top out-of-state station, top Alabama fixed/portable station, and the top Alabama mobile station. Certificates will be awarded to the top scorer from each state, province, country, and Alabama county. Certificates will also be issued for top Novice and Technician scores in and out of Alabama.

ENTRIES:

Mail entries by March 15, 1986, to Bill Levey WA4FAT, 3629 Dabney Drive, Birmingham AL 35243. Include an SASE for results.

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73 Magazine, Pine Street, Peterborough NH 03458, USA, Attn: International Editor.

AUSTRALIA

J. E. Joyce VK3YJ
44 Wren Street
Altona 3018
Victoria
Australia

Following the short report in an earlier column about the 150-year celebrations in VK5, a letter sent to me by Mr. Graham Horlin-Smith VK5AQZ should be of interest, I feel, to any group planning a similar event. Graham is a controller of the South Australian 150-year celebrations, and the following is his report:

THE VK5 150-YEAR REPORT

Eighteen months of planning to link amateur radio with S.A.'s 150th birthday in 1986 reached fruition on Monday, May 27, 1985, when VK5JSA, the special-events callsign, was activated from the center of the city of Adelaide. The location was the Renaissance Center which overlooks the Rundle Mall.

Three operating points were established. At street level, a group of HF operators worked two rigs from an OB radio van, a Kenwood 930 and a Yaesu 757GX out of a 204 BA, 4-element monobander and a 40/80-meter trapped dipole, respectively, located on the roof of the seven-story building about 200' above ground level.

The second operation for CW and RTTY was located in Radio Rental's (Adelaide) ground-floor shop window (5-band trapped vertical also at 200'), and the third consisted of UHF/VHF, ATV, and a satellite display on the 6th floor (the restaurant), which had a commanding view of Adelaide and Repeaters 5 and 8 in the Adelaide Hills.

Computers by ICL demonstrating the link with amateur radio and substantial visual displays by the WIA S.A. Division, International Communications Services, Dick Smith's (Adelaide), the Department of Tourism, and the Jubilee-150 Committee complemented all operating points. Outside scenic lifts open into the restaurant, and an average of 2,000 visitors daily had direct eyeball contact with amateur radio during the week's operation.

The activity launched a program which will continue throughout 1986. As a result of this and other planned activities, VK5 amateurs expect to propagate 100,000 special Jubilee Souvenir QSL cards worldwide and 2,000 awards during 1986. The special issue welcomes amateur participation in S.A.'s 2,000 plus planned Jubilee programs and extends "Happy Birthday" greetings to S.A. in eight different languages. The first Grand Prix to be held in Australia will coincide with the commencement of a year of birthday parties. December 28th was S.A.'s Proclamation Day, and 1986 is its 150th birthday or sesquicentennial year. Come on over and enjoy S.A.!

S.A. has chosen to share and twin its 150th-year celebrations with Texas (Adelaide and Austin, Texas, being linked as twin cities). In excess of 170 towns and districts and 300 schools have been distinctively linked and exchanges have already commenced. S.A. amateurs see a role in providing the communications link to assist, where possible, with towns, schools, activity groups, and community and service organizations—a daunting task, but looked upon as a real challenge with a spirit of adventure which hopefully will be rewarding insofar as the hobby of amateur radio is concerned. Promotional-type activities and working with Jubilee activities, it is hoped, will provide a positive exposure of the hobby as well as an awareness and a better understanding of amateur activities in the long term.

"Amateur Radio Week, Promoting S.A." fired the first shot and launched the program. The official launch was by Dr. Ian McPhail, Chairman of the Bi-State Centenary Committee, in the VIP area of the Renaissance Center Restaurant on the 6th floor. Escorted tours, press releases, and media involvement in amplified amateur-radio links with Texas via San Francisco into the Mall focused the public's attention on amateur radio. Later, special appearances by Mr. Gavin Keneally, the Hon. Minister of Tourism and Local Government, and a special amateur link between Adelaide's Lord Mayor, Mr. Jim Jarvis, and Austin's Mayor Frank Cooksie were scheduled.

The WIA Committee of Jenny Warrington VK5ANW, Rowland Bruce VK5OU, and VK5AQZ acknowledged the financial sponsorship of the S.A. Department of Tourism, Estrow (Civil Engineers and Supervisory Consultants), Radio Rentals, International Communication Services, Dick Smith's, The Electric Bug, Captain Flash Advertising, Norman's Estates Winery, ICL, the South Coast ARC, the Renaissance Center Management (Emanual Group), Sound Out Services, the Renaissance Tower Restaurant Management, and the many amateurs themselves who contributed time and effort.

STICKY TAPE AND STRING

The problems of erecting temporary HF antennas on the roof of a city building were many. The most important consideration was to ensure safety for both the crew erecting the antennas and the general public below. Members of the antenna crew were no real worry, because one look over the side of an eight-story building is all it takes for self-preservation to take over; any thoughts of daring deeds vanish instantly.

The safety of the public is another matter. We had to erect an efficient antenna system that would stay put for the duration of the project, not fall off the building and cause injury below, not to mention rearranging the vswr and element spacing of the antenna.

The antennas we decided on were a 204 BA, 4-element, 20-meter monoband yagi, which was kindly made available to us by a gentleman from the near country, a half-wave dipole on 80 meters with traps for 40 meters, a couple of trapped verticals, and a VHF Slim Jim.

The installation of all these antennas took one and a half days working at a moderate pace, and although the roof now resembled an elaborate bird trap, antenna performance was interesting if not predictable.

The 204 BA exhibited a vswr of 1.1:1 right across the band. I suspect that the 300 meters of RG-8 might have been responsible for making it look slightly better than it was. The dipole, also fed with 300 meters of RG-8, underwent apparent vswr changes, as originally it was tuned using a short feeder. However, the result was still reasonable and well within the scope of the automatic AT units used. These antennas enabled the station to transmit strong signals, and generally we received very good reports.

Due to a high noise level, reception was not as good as we had hoped. The noise problem was the result of a trade-off between going for the efficiency of elevation and the local noise generated in the elevator control rooms. The trapped verticals, needless to say, were particularly susceptible to the noise, and as a result they weren't very successful.

Surprisingly, the Slim Jim performed well in spite of the tact that it also was fed with 300 meters of RG-8.

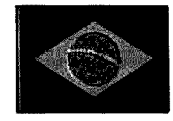
When the antenna crew assembled to disassemble the installation, one gentleman (as usual) was heard to suggest cutting the guy ropes and running. When handed a sharp knife and told that we would wait under several feet of concrete, he retracted his suggestion, we reverted to the original plan, and the antennas were lowered safely in about two hours.

NEW TOWER LEGISLATION IN VK3

New planning controls have been introduced in the Metropolitan area of Melbourne. After a long battle by the WIA, with many submissions to the planning authorities on behalf of all amateurs, it seems we have again gotten the short end of the stick. It also appears that no matter what we do in the way of community service, we amateurs are still a minority voice, as you will note by the regulations.

TV viewers can have antennas on thin towers as high as they like; CB operators can have their 4- or 5-element yagis up in the air with virtually no control, but we amateurs are governed down by the regulations if we want beam antennas on 15, 20, or 40 meters. Part of the new regulations follow:

A Radio Mast is a mast which, together with antenna:



(1) exceeds a height of 14 meters above ground,

(2) when attached to a building exceeds a height of 5 meters above the roof line,

(3) has any horizontal distance in excess of 6 meters, or

(4) has a structure, not including the antenna, exceeding 50 centimeters in width at any point in excess of 3 meters above ground level.

With the attitude of some of our local councils, any new amateurs, without prior council approval, will have little hope of getting even a 15-meter dipole up into the air, let alone a TH6DXX at a reasonable height.

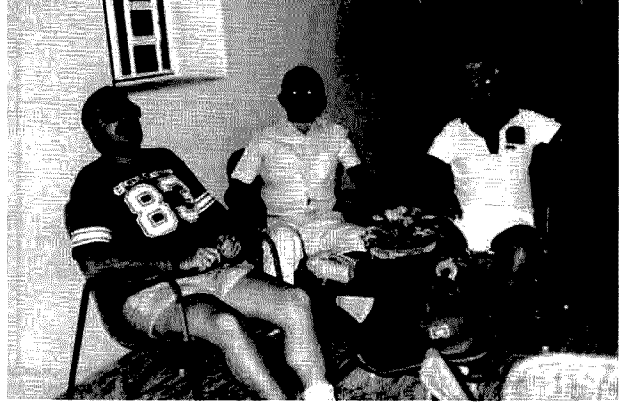
PAULO SIMPLICIO PY7AQA

As I have written before, sometimes I have to travel due to my job. During these trips when I have free time, I like to visit friends, most of them known for more than twenty years through our contacts on radio.



On my last trip to Recite (State of Pernambuco), I asked Bart PY7AKW (ex PY0CQ and PY0DX on St. Peter & Paul Rocks) to go with me to Timbauba, a very small city with many shoe factories. As you surely know, Brazil is the greatest exporter of shoes to the United States and you may be putting on a pair made in Timbauba.

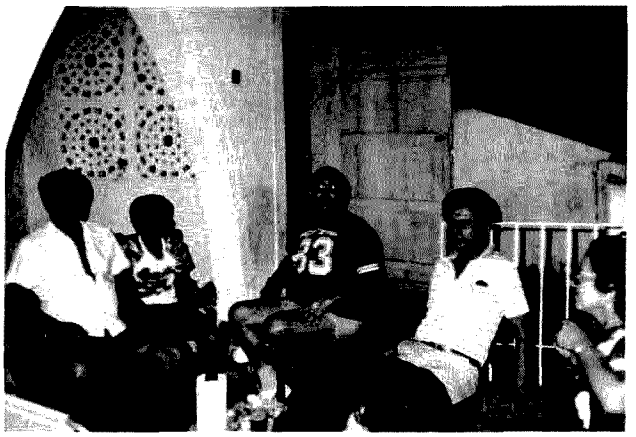
In that city I was anxious to visit Paulo Simplicio PY7AQA, who is the first licensed amateur there. He is a very well known person by everybody. We didn't have his address, but it was not difficult to reach his house. We just asked people and they showed us the direction. The house was located on a very narrow street near the main square.

The last time I met Paulo personally was about eighteen years ago. On the bands he had an unmistakable voice—very grave and sounding like a thunderstorm.

Unfortunately, he lost that beautiful voice, so we will never hear it again. He got sick with cancer, and the doctors removed the upper part of the trachea containing the vocal cords.

He told us that after this serious sickness he thought that he would not have

L to R, PY1APS, Paulo PY7AQA, and Bart PY7AKW.



more than a few months of life, so he refused to learn how to speak again. After the first lesson, he gave up, disappointed.

In this way he lived for a few months. One early morning, he got up suddenly and told himself, "I am a man; I am not a cat!" At that moment he tried to work out how he could pronounce a syllable.

Day after day Paulo did the same. Nobody at home, even his wife, knew about his decision. A few months later he was able to speak again, and when his wife came to the breakfast table one day, he said, "Good morning—how are you?" Tears were a sign of their happiness.

Paulo himself wanted to tell the good news to his doctor, to surprise him also. . .and he did. In spite of many years in his profession, the doctor could not believe what he was hearing. Paulo PY7AQA was such a perfectionist that he had developed his own method, and he was talking almost as a normal person.

On our way home we stopped in Olinda and visited Firmino PY7SJ and Ivanildo PY7MM. We had oysters and beer and reflected upon the excellent day we'd had.

L to R, Firmino PY7SJ, PY1APS, and Ivanildo PY7MM.

AMATEUR SERVICE RULES REVISED

The Wireless Planning and Coordination (WPC) Wing of the Ministry of Communications of the Government of India, by a notification dated October 4, 1985, has revised the Indian Wireless Telegraph (Amateur Service) Rules, 1978, to include more bands and operating privileges for different classes of radio amateurs in India.

A little while ago, when the Restricted Class License—the then no-code license—was introduced, the holders were authorized operation only on the 144-146-MHz band. With this revision, they are authorized both 144-146 MHz and 434-438 MHz on A3E, H3E, J3E, R3E, and F3E modes. Only terrestrial operation is permitted for which the maximum power usable is 10 Watts.

For holders of the Grade II license (the next higher class), the frequency and power authorized on V/UHF is the same. However, they are permitted to operate on A1A, A2A, F1B, and F2A modes also. The major changes for this category of license are in operational parameters—they are now allowed A1A, A3E, H3E, J3E, and R3E modes—on HF bands. However, authorization to work on voice modes is subject to the submission of proof of having made at least 100 contacts with other amateurs on CW. The new bands added on HF are 1820-1860 kHz and 3500-3700 kHz.

Grade I license holders, in addition to the modes permitted for the Grade II license holders, have A2A, F1B, F2B, F3E, F3C, A3C, and A3F modes on HF, VHF, and UHF. The maximum input power continues to be 150 Watts on HF and 25 Watts on V/UHF terrestrial. Additional bands given are 1260-1300 MHz, 3300-3400 MHz, and 5725-5840 MHz. Amateur satellite operation is also permitted in the appropriate subbands with a maximum output (eirp) of 30 dBW.

The holders of the Advanced Class license, the highest category possible for a radio amateur in India, are entitled to all the privileges of a Grade I license and are authorized to use up to 400 Watts dc input in the following subbands: 3520-3540 kHz, 3890-3900 kHz, 7050-7100 kHz, 14050-14150 kHz, 14220-14320 kHz, and 21100-21400 kHz. On VHF, the maximum dc input is 50 Watts for terrestrial operation.

In general, radio amateurs in India have almost all the frequency allocations possible in Region III, the best being the 1820-1860-kHz and 3500-3700-kHz allocations. This is especially true at this time, when the MUF goes down considerably as night sets in. And for the research-minded experimenters, the bands above UHF also are available. The allocation of 1820-1860 kHz is on the primary shared basis; 18068-18168 kHz on non-interference and the non-protection basis, and 1260-1270 MHz for Earth to space, Satellite Service only. We hope that these new authorizations of emissions and frequencies will boost up amateur activity in India considerably.

INDIA CATCHES UP

One of the main demands of the Federation of Amateur Radio Societies of India, in their discussions with the Communications Ministry of the Government of India, was that all international allocations to the amateur service should be available to Indian amateurs.

After some foot-dragging and half-hearted releases of some band segments during the past two years, WPC (the Wireless Planning and Coordination Wing—India's FCC) has now gone the whole hog and announced a complete revision of the earlier allocations. The new announcement opens up all the HF, VHF, UHF, and microwave amateur bands to Indian amateurs, with the notable exception of the 6-meter band.

This relaxation is generally in line with the liberalization in all spheres—particularly radio communications (more on that in a later column). In a strange anomaly, 2-meter hand-helds still cannot be used in the mobile mode without a special 90-day authorization involving a US$0.80 fee and interminable waiting! In the generally liberal atmosphere, however, everbody ignores this requirement and nobody has ever been cited for breach of the law!

THE MEXICAN EARTHQUAKE

It would seem that with the huge distance separating Israel and Mexico, the earthquake disaster would have had very little repercussion here. However, as it turns out, with Israel's rich ethnic mosaic, there are many thousand Israelis with relatives in that stricken land. What ensued was one of the largest, if not the largest, public-service operation in the history of Israeli amateur radio.

When news of the disaster was given by the local media, it was stated that since all normal channels of communications out of Mexico had been disrupted, the only means of relaying messages was via radio amateurs. Almost immediately, hams all over Israel began to receive phone calls from people concerned about the fate of their dear ones in the disaster area.

One of the first contacts was made between David Ben Bassat 4X4WH (see photo) and Shimon Kushnir XE1GGU. The amateurs around the country organized themselves, with amateurs in each city receiving phone calls from those concerned, collating them, and having the messages handled by those in contact with Mexico. The radio and TV gave out the phone numbers of the key amateurs in each area, and for a week the phones were ringing almost nonstop at their homes.

With the ionosphere being quite fickle at this time of the sunspot cycle, especially over such a long haul as between Israel and Mexico, stations in between helped out with the relays—such as Mel G4WMP and two Washington area hams, David K3STM and Jim K3JW, who put in overtime. Later on, about a week after the first quake, the Ministry of Communications eased the strain on the ionosphere by putting in a free telex line to K3JW from Israel.

As well, early on in the operation, a list of the areas of Mexico City that were struck or were OK was circulated among the amateurs so that in many cases they could put callers immediately at ease. The "mailbox" in the Haifa RTTY repeater was pressed into service, carrying a lot of the message load, and proved to be quite instrumental in easing pressures.

When the operation wound down, about a week and a half after the earthquake, thousands of telephone calls had been processed. Quite a few amateurs had literally worked themselves to exhaustion, and a few score had been involved in this public service. Amateur radio had received, once again, so soon after 4Z4ZB's contact with the space shuttle, great publicity, with pictures of 4X4WH and his station and antennas having appeared on the national TV news.

I have really not even begun to name the amateurs here who worked hard in this endeavor, as they are many, and I would doubtlessly risk overlooking a few. Hats off to them all!

Inauguration ceremonies at the Silent Keys' Forest. (L to R) Shlomo Ariav and Mrs. Vicky Alkalai, Forestation Authority, Ozzie Osrin 4X4CW, and Aharon Kirschner 4X4AT. (Photo by 4X4GT)

THE SILENT KEYS' FOREST

One of the most popular ways that we in Israel remember those who have passed on is the planting of trees, a living memorial to them. With this custom in mind, Ozzie 4X4CW, the chairman of the Israel chapter of the Quarter Century Wireless Association and Israel's first licensed ham, conceived the idea of a grove to commemorate our Silent Keys.

After negotiations with the Keren Kayemet (JNF), the Israel Reforestation Authority, and a drive amongst hams and the families of the Silent Keys, enough money was raised for the planting of the grove, and daily contributions continue to come in for more trees.

On October 22nd, the Silent Keys' Forest was officially inaugurated with a ceremony at its site in the Ben Shemen forests in the hills overlooking the coastal plain near the Ben Gurion airport. The view there is quite spectacular, and it is indeed an ideal spot for Field Days that no doubt will be held there in the future.

Ozzie 4X4CW (left) watches General Mordechai Bar Dagan and Prof. Amnon Rubenstein shake hands at the Silent Keys' Forest ceremony. David Ben Bassat 4X4WH is behind, and Froike 4X4AF is on the right. (Photo by 4X4GT)

At the ceremony, many VIPs were present, including the Honorable Professor Amnon Rubenstein, Minister of Communications, Leland Smith W5KL, president of the QCWA who had come in from an archaeological trip in Egypt for the occasion, the chief officer of the Israel Defence Forces Signal Corps (General Mordechai Bar Dagan), the head of the Keren Kayemet Reforestation branch, and, of course, the Israel Amateur Radio Club officers and those responsible for seeing the project through. The event was attended by over two hundred amateurs, their families, and families of the Silent Keys.

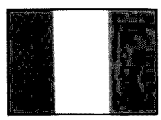
Speaking at the podium, the Minister of Communications praised the hams for their strong record of voluntary public service and said that in the expected era of peace, radio amateurs will play a vital role, helping to build bridges between us and our neighbors, replacing hostility with friendship.

The ceremony closed with the planting of saplings by the families of the Silent Keys and the VIPs. Although the forest is really only in its infancy, with about 2000 trees donated, already picnic tables and benches are there, and it will be a place close to the hearts of all the radio amateurs in Israel.

THE TEL-AVIV-JAFFA AWARD

A new award has been made available to licensed amateurs and SWLs called the Tel-Aviv-Jaffa Award. Issued by the city of Tel-Aviv-Jaffa, it is in color, bears a picture of the city's boardwalk, and is signed personally by the mayor.

A minimum of ten points is required, Tel-Aviv stations counting for one point, Jaffa stations for five, and if you were fortunate enough to have worked 4X75TA when it was in operation last year during the 75th anniversary of the founding of Tel-Aviv, then you receive ten points for that contact. Only contacts made after January 1, 1984, count.



Do not send QSLs but rather a list containing the details of all the contacts; the list should be signed by two other licensed amateurs. The fee is either $3.00, 8 D.M., or 2 pounds sterling, and all the above should be sent to the award manager: Shlomo Mussali 4X6LM, PO Box 8225, Tel-Aviv 61081, Israel.

YAWN

In these days of rapid developments in technology, yesterday's achievements are taken for granted—commonplace. Such was the case on Saturday, November 2nd, when one excited ham phoned the hot line of a popular radio station to be the first to report on 4X4AS, 4X4GI, and 4Z4ZT making direct two-way contact on FM with DJ0SL on the orbiting Spacelab during orbit 41. (On all other orbits, DJ0SL only made recordings of calling stations.)

The voice at the other end of the telephone answered, "So what?"

After the huge publicity received by 4Z4ZB's contact with W0ORE on a previous flight of the shuttle, apparently this is no longer news. Incidentally, this was 4Z4ZT's first satellite QSO, using only a 5/8-wavelength whip, and, in his excitement, leaving his set in the 5-Watt position!

ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
21029 Milano
Italy

We had the opportunity some months ago to introduce you to I0FCG—Francesco Cossiga, the President of the Italian Senate. The most important information to report to you now is that he has been elected President of the Italian Republic.

The Knights of the Laid Table.

HV2VO and KD7RQ with I2SM.

He has received close to 90% of all the votes of the Parliament and the Senate and surely the support of 100% of the Italian hams.

The press has not reported correctly his ham activity, having some confusion with CB, but our hobby has received a lot of free "advertising" in all newspapers.

A few minutes on the first channel of the national television have been devoted also to Andrea I8WY—who at the end of July contacted the space shuttle on two meters. A simulated contact with the recording of the QSO has been shown during the main news broadcast.

The RadioRivista, the magazine of the Italian League, is devoting more space to microcomputers. From a survey it appears that locally the average amateur is 37 years old, is interested in computers, has tried at some time to build something himself (mainly antennas), and is interested in awards (37% have obtained the local awards while 31% are in some way interested in the DXCC).

Our average ham is reading 2.75 magazines devoted to radio or computers per month and spends $600 per year for rigs. He is mainly using SSB (92%), some CW (42%), and FM (66%). He likes to exchange QSL cards via bureau (62%) and direct (73%), even if this second method does not work too well.

This first survey will be followed shortly by a second one on a broader basis, and it will be very useful to give to the League some indications on the policies to follow in the near future.

A new contest group has started operating from the Milano area. It consists of three hams, Giorgio I2VXJ, the ARI Contest Manager, Paolo I2UIY, the Secretary of the ARI DX Club, and Mario I2MQP, the

Leland Smith W5KL, QCWA world president (right), Helen Smith WA5WAR, and Shimshon Lotan 4X4GF at the Silent Keys' Forest ceremony. (Photo by 4X4GT)

I2BVS operating from IB0.

HF and DX Manager. The group has been called "The Knights of the Laid Table" and intends to participate in all the main contests. One problem during the first operation was that no one agreed to operate while the others were eating—he was afraid to find nothing left for him.

If you look at the photo you will understand. I2UIY and I2VXJ are with guest operator Jimmy WA2JNN during the WPX CW. It was one of several pizza breaks, and from the pizza size you can understand it was not a short one. It can jeopardize results, but it does not matter. Food, wine, and *dames* are our main interest; radio is only second.

1K2DVG, I2CZQ, and I0GPY operated from HV2VO. Many contacts have been made on the low bands from the Vatican, thanks to a special antenna, a vertical wire 80 meters high, erected with a small aerostat. It has performed very well on 80 and 160 meters and will be used again in the future.

Another photo shows HV2VO with KD7RQ and I2SM.

Max I2DMK

Let's give a look to what has been done by I2DMK during his 26th and 27th expeditions. The first was from June 4 to 12 with Max I2DMK and Enzo I2BVS to IB0, Ventotene Island, IOTA EU 45. The island is in the Tyrrhenian Sea, 15 miles from the coast. It is 2 miles long and less than 1 mile wide. It was used for a prison during the Roman Empire and during the last war. A GP for 40 and 80 meters was installed together with a 2-element beam for 10, 15, and 20 meters. 4500 QSOs were made, 60% CW and 40% phone. On June 8, the island of Santo Stefano was activated on all bands with 400 contacts. The station was installed in a sentry post of the old penitentiary.

August was the month of the expedition of Max I2DMK to Stromboli, IOTA EU 17, with the usual callsign of I2DMK/ID9. Operations were on all HF and VHF bands, both CW and SSB.

Stromboli Island has a surface area of 5 square miles, and it has the only volcano in Europe where perennial eruptions come from its three mouths, shooting incandescent masses and burning lapilli towards the sky.

For both operations, QSL via I2MQP

IARU CONFERENCE, 1985

1985 was the Diamond Jubilee of IARU, and New Zealand was honored to be the host country for the Region III Conference—the 60th anniversary of the founding of the International Amateur Radio Union. It was held in Auckland.

The IARU is the link between over 2 million radio amateurs in 122 countries and the International Telecommunications Union, of which the Amateur Service and the Amateur Satellite Service are part. Formed in 1925, the IARU has observer status at all ITU conferences. It is controlled by an administrative council drawn from its three regions and an International Secretariat provided by the American Radio Relay League. The Regions of IARU are Region I, Europe, Africa, and the USSR; Region II, the Americas, and Region III, the rest of the world.

NZART is a founding member of the Region III association and plays a leading role in its activities. Each IARU Region holds a triennial conference so that there is a regional conference each year.

As NZART was the host society, I will report on the event in my next column.

RAOUL ISLAND

Chris Hannagan ZL8OY/ZM8OY will be operating from Raoul Island (Kermadecs) through September, 1986, while on a tour of duty at the weather station on the island. Chris will be operating mostly in the evenings (about 0600Z onwards) on the usual DX slots of the various frequencies, both phone and CW. He does NOT operate nets or lists. He will be using an ICOM 701 and a home-brew linear on the HF bands and an ICOM 560 for six meters.

Antennas will be delta loops for 80 and 40 meters, a three-element TET yagi for 20/15/10 meters (if the parts arrive in time), a vertical for 160 meters, and a five-element yagi on 6 meters.

Chris looks forward to many QSOs while on Raoul—many DX operators will have worked him when he was on Chatham Islands recently, and may also have worked him from the Auckland Islands—all QTHs Chris has been to on tours of duty with the weather service. QSLs to ZL4OY (Chris Hannagan, The Terrace, Warrington, Dunedin, New Zealand) or the QSL Bureau will be handled during his absence by his XYL.

WARNING

Recently an amateur received a warning letter because his station was not being operated in a manner in keeping with the spirit of amateur radio and the regulations. He had been monitored by the official monitoring station, which observed the following: The station tried to break into a conversation between two other overseas stations by repeating just the first two phonetics of his station callsign over and over. He repeated this continuously for 20 minutes before he was finally acknowledged. Only then did he give his FULL callsign.

How often do we hear this on the DX bands? Harmless enough, some might say, but it is in conflict with regulations because it creates "harmful interference." Infringes on the proper use of the callsign, and is way out of line with the Amateurs Code. Think how other amateurs hearing outbursts of this type would judge fellow amateurs in the offender's country. Consideration for others is a virtue not practiced as well today as it used to be in my early days of ham radio.

POLAND

Jerzy Szymczak
78-200 Bialogard
Buczka 2/3
Poland

The IX National Congress of PRAA, which took place in Warsaw, adopted a program of activity including work on crucial problems of development of the Association. The Congress recommended that PRAA reconsider the organizational structure of the Association and even to liquidate non-active, small District Boards. The Congress also recommended restricting the number of domestic competitions and certificates.

The PRAA planned to obtain permission to work with portable and mobile devices, with a second QTH, and on new bands for its members. The Association would work for cancellation of the order of the Ministry of Communication allowing possible refusals to issue or the cancellation of a ham license without giving the reasons. The Headquarters of PRAA hoped to publish a register of Polish amateur-radio stations and bring it up to date.

The PRAA will collaborate with other institutions to work out national standards for technical parameters of electronic devices relative to their electromagnetic compatibility.

The following were selected to PRAA: Jerzy Rutkowski SP5JR, President; Wiktor Chojnacki SP5QU, Stanislaw Maciejkiewicz SP2JS, and Pawel Kaniut SP9RG, Vice Presidents; Secretary General—Jerzy Miskiewicz SP8TK; Treasurer—Zbigniew Klossowski SP4BQW; SW Manager—Jacek Rutyna SP9AKD; UHF Manager—Zbigniew Malik SP6AZT; ARS Manager—Jerzy Klabon SP3FFN, and Member in charge of propaganda and youth—Jan Ladno SP5XM.

I will write later on what the PRAA work accomplishes.

In April, 1985, a respected member of PRAA, Wiktor Chojnacki SP5QU, died. His writings informed readers of *Polish Ham* magazine about current events in the radio-amateur movement. Editor-in-chief of the *Bulletin* of PRAA, he prepared his twenty-fifth jubilee issue. SP5QU won the second prize of "Master of Technology" for collaboration on the production of a radiotelephone, "Klimek," for needs of the mountain rescues. The Polish radio-amateur movement has lost a strong friend.

The first Conference of the Polish Radio-Videography Club took place in Torun in May. Present were 104 delegates from Poland and the foreign visitor, Y23NE. A sports commission verified QSLs and granted the first licenses for the full members, SP2JPG, SP3CMX, and SP3LRS. Lectures were delivered on club activities by SP2JPG, SP2DDV, SP3CAI, SP3CMX, SP3LRS, SP3GAX, SP6GTN, SP6NVA, SP7CHY, SP8JMW, SP9BWJ, and Tomasz Ilkow.

Many participants demonstrated their home-brew items and others brought factory-made devices. The resolution committee prepared a comprehensive report for PRAA authorities.

Polish hams took part in international contests in the last three months of 1985 involving Oceania, Spain, Portugal, America, Australia, and Canada.

SATELLITE TV IS HERE

According to the Mayor of Lagos, a parabolic dish will be installed in Valverde for the reception of satellite TV signals from several TV networks. Talks with the Secretary of State for Communications have started to find out the best place for construction of the receiving station.

The project is part of an official program which will include installation of several other dishes, one in Santarem and two in Lisbon. The priority project will be the one located in Valverde due to the big concentration of visitors in that particular area to the several well-known holiday resorts.

But this isn't all. Similar equipment, on a reduced scale, was built and installed by a small group of CT operators where French and German hams also were involved. With this simple but effective homemade TVRO, they've had good results. Signals from several European TV networks were seen without too much trouble (HI).

WORLD TELECOMMUNICATIONS DAY

This year, the events for this celebration took place in Oporto. The Associacao Portuguesa Para O Desenvolvimento das Telecomunicacoes (Portuguese Association for the Development of Communications) put together an interesting schedule with other state departments in this field. They were to let people know a little more about the wireless world; they were appreciated by students, technicians, engineers, etc.

FIRST CONGRESS OF TELECOMMUNICATIONS

If everything goes on schedule, this important meeting will be held this month (February, 1986). It will be devoted to developments and changes. Foreign representatives are expected. Forum Picoas in Lisbon (opened recently) has all the facilities needed for such meetings, so the Congress will be there.

VISITORS IN LISBON

Once again, we've had a visitor here in the shack, Tom Phipps KA4CSG, from Texas (I'm sorry, Tom! We don't have any rodeos in this country) was here and we had a nice chat. Many thanks, and keep crossing the Atlantic. You are always welcome.

Tom Phipps KA4CSG, Ft. Hood, Texas, left, with CT4UE.

NEVER SAY DIE

WELL, I'M BACK

I'm deeply concerned about a type of mental illness, spread by hams, which is going around. It's not a new one—actually, it's shown signs of dying out in recent years. It's a virus-like illness which can hit people at any age, but which tends particularly to hit boys around puberty. For the lack of a better name, I call it the Ham Infection—HI.

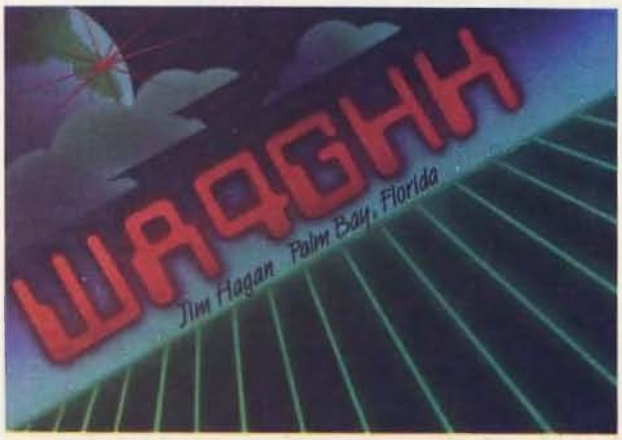
I remember the first time I was exposed to it. I was about ten and my grandfather introduced me to Fred Stevenson W1CUN. Fred was slouched in a little building out in back of the Valley View Hotel in Bethlehem, New Hampshire, his legs intertwined in a chair, with his obviously home-made ham rig, built on a board, blazing away as he talked. I can still see it. And how incredible that 15 years later I'd be operating my own ham station from this very same shack.

You can bet I began tuning any radio with a shortwave band on it up above the broadcast band—past the police calls at 1600 kHz—to hear the hams talking on the 160-meter band. Wow! I'd been infected.

Oh, I suppose I was predisposed. My mother's father was an inventor—made over a million at it back in the 20s when that was a lot of money. He was into the high tech of his day—invented the first thermostat for gas stoves, for instance. My father was into flying, the high tech of his day. So I was a sitting duck when Fred happened to me.

Now, every one of you reading this is a carrier of this mental illness. Yes, you have the power to infect dozens—even hundreds—of susceptible youngsters. I've known some hams, like Bill Welsh W6DDB, to infect thousands. He even infected his wife, Marie W6JEP! Women, for some reason, are usually resistant to HI.

Speaking of wives, I realize that many of them think of HI as a dread illness, one which siphons money from the family income for expensive ham rigs and ugly towers with sprouting antennas to make their homes eyesores in the neighborhood. The accompanying TVI alienates many of the neighbors. Heck, she can't even get the OM to go to work if a rare country he hasn't contacted is scheduled to be on the air. And then there are all those weirdos who track dirt through her living room, going into the hamshack to talk gibberish!



The Ham Infection is different from most mental aberrations, such as religion and politics, both of which require extensive exposure to become established. The Ham Infection can happen in minutes—and last a lifetime. It's in some ways like narcotics or alcohol in that those of us who have it enjoy it—it's our families and friends who suffer.

The answer to that problem is simple—infect as many of your family and friends as you can. Then you'll all enjoy the madness together. Let's get together on this and pool our resources. I know some ways to spread HI, but I'll bet you know many ways I haven't thought of yet. So drop me a note with your suggestions on what you've found successful.

Remember, our mental problem is only an aberration because there are so few of us—less than 0.2% of the US population. In Japan, where about 1.6% have HI, it's almost respectable. It looks as if we might begin to see daylight at around 1%—about 2.2 million licensed hams. That's a good goal, right?

Not to throw cold water on you CW fanatics, but if Fred had been batting a key around instead of talking over his ham rig back in 1931, I'd probably be a lawyer today. And heaven knows we sure don't need another lawyer. Some of my best friends are lawyers, but I sure wouldn't want my daughter to marry one.

QRX. . . .

EDITED BY PERRY DONHAM KW1O

RM-5241

DON STONER W6TNS has filed a Petition for Rulemaking with the Federal Communications Commission which would establish a **Public Digital Radio Service** in the amateur six-meter band. In his (very convincing!) petition, Stoner outlines the need for the new allocation by describing the explosive growth in the use of modems, the plummeting price of personal computers, and the sharp increase in the cost of accessing the telephone network. Don believes that these three factors make the time ripe for a low-power digital service. Why six meters? According to Stoner, "Out of 400,000 radio amateurs in the United States, less than 1,000 are active in the six-meter band." He goes on to state that, due to the potential for interference to TV Channel 2, nearly all amateur operation is in the lower 2 MHz of the amateur band (50–52 MHz). It is the band from 52 to 54 MHz that Don wants to use for the new service. The technical specifications for the PDRS are very stringent and specific: 1 Watt maximum transmitter output, use of only vertical antennas, and prohibition of remuneration are a few of the details that are laid out in the document. The channel usage would be very similar to our own packet-radio system, with only one channel being occupied by multiple stations using collision-avoidance schemes. Is it really time for a digital Citizens Band? I say it is. The ARRL's "Super Novice" ticket will fill a void in the amateur structure, but a new license-free computer-to-computer allocation is something that millions of telecommunicating Americans are hungry for. The FCC has assigned Stoner's petition RM-5241.

FEMA Fans

A PAIR OF HAMS from the Westchester (NY) Emergency Communications Association recently let their government know just how important amateur radio can be in a disaster. **Rich Moseson N2BFG and Don Storm K2MQR** spoke before a disaster-preparedness seminar sponsored by the Federal Emergency Management Agency. The talk included a video tape of hams performing emergency communications during disasters in California, and a handout containing names and telephone numbers of local amateur emergency personnel. Several seminar participants claimed that the duo's presentation was "the most interesting and educational of the day."

Looking

IF YOU WERE STATIONED with the **14th AACS Squadron** headquartered in Cairo during World War II, it's reunion time! Get in touch with one of these fellows for details: Bob Irons W9CSJ, Bill Eiler K9OIW, Ted Werling WA9OPJ, Paul Baumgarte WD8RJR, Chuck Cohen W2FQ, Art Masters N4LZX, Bill Ulbright W9LLQ, or John Fisher W1CLF.

CQ Ma Bell

WE MISSED THE BOAT on the no-code license, but New England Telephone was not so myopic! If you live in the Worcester, Massachusetts, calling area, you can dial **Phone-A-Friend**. This is an experimental service in this exchange which lets you dial a number and be connected with up to five other callers. At random. Sound familiar? There are separate numbers for "juvenile" and "adult" conversations. Sort of like the difference between 2m and 160m. And who knows? If this experiment is successful, AT&T may expand it to cover the entire country—and we'll finally get our no-code ticket.

Another Celeb

JOINING THE GROWING LIST of ham celebrities is Italian President **Franscesco Giuseppi Cossigna I0FGC**. Other dignitaries include Barry Goldwater K7UGA, Indian Prime Minister Rajiv Ghandi VU2RG, and Jordan's King Hussein JY1. Wouldn't it be great to get all of these folks together in one place? I would *love* to see the Prime Minister with an HT on his belt and a Dayton Hat-tenna on his head.

My callsign, eh?

MANY CANADIAN AMATEURS have been asked by the Department of Communications to give up their Q-signal suffixes. While the letters received by stations such as VE7QST are requests, not orders, the DOC has stated that they will no longer issue calls with Q-signal suffixes.

Tick Tock

THE CANADIAN DOC is also moving right along with their plan to restructure the Canadian Amateur Service. According to a report in the *CRRL News*, the majority of VE hams think that the proposal is a good one and do not see the no-code license as a detriment to the hobby. Briefly, the proposed structure is this: Three amateur certificates (licenses) will be available. Certificate A will have no Morse proficiency test. Holders will be given all modes on frequencies above 30 MHz, with a power output no greater than 250 Watts. Also, Certificate A licensees must use only commercially-built transmitters. Passing a 12-wpm Morse test will upgrade Certificate A to Certificate B, which adds all modes on frequencies below 30 MHz. A written examination on advanced electronic theory is required for Certificate C, which allows the holder to use homebrew equipment, transmit with up to 1,000 Watts output, and become a license holder for repeater and remote stations.

Where Am I?

THE TOP SECTION of our Top Band is no longer exclusively an amateur allocation. In order to provide additional spectrum for radiolocation systems that may be displaced by an expanded AM broadcast band, the FCC has given those systems primary status on the band from 1900 to 2000 kHz. Amateur stations may use this segment on a non-interference, shared basis and cannot expect protection from radiolocation signals. It's not as bad as it sounds, though, since the locators will be using spread-spectrum techniques: We may not even know they are there. Also, the FCC is not accepting applications for the new allocation until July of 1987.

Form Format

DON'T USE any FCC Form 610s issued prior to June, 1984, to apply for an amateur-radio license. If you do, the Commission will simply return your applications with a request to use the proper form. You can get copies of the new paperwork from your regional VEC, your nearest FCC Field Office, or the FCC Consumer Assistance Branch, Private Radio Bureau, Gettysburg PA 17325.

Bugged Beads

THE LAST THING a guy wants to worry about is his beads, right? Well, start worrying! **CCS Communication Control, Inc.**, recently discovered worry beads which contain an ultra-miniature radio transmitter. In the Middle East, worry beads are ubiquitous—they are carried to business meetings, while traveling or dining, and so on. CCS was called into action by a gentleman whose business dealings were somehow being leaked to his competitors. What the company found was two sets of beads with a tiny transmitter and a battery built into the largest bead; the transmitter had a range of about one kilometer.

Japan's Hush-Hush Rushbox

These units were ordered destroyed after WWII, but a few fell into the hands of collectors. Now, after 40 years, PA0SE analyzes the Imperial Army's secret radio.

Communication equipment used by the Allied forces during WWII has become well-known among amateurs, no doubt because enormous amounts have been sold by war-surplus shops for decades after the war ended. Quite different is the situation for German war-surplus material, even here in Europe near to the source of it. The explanation is that the Allied commanders were ordered to destroy all German war equipment that was found after the surrender in May, 1945. Some communication equipment escaped demolition, however, and now rests in museums and with collectors all over the world.

Whether a similar order was issued for Japanese wartime equipment is unknown to me, but the fact is that very few of those items found their way to collectors. This is true in Europe, at least, but I think the situation is not much different in the States. So it was with considerable joy that I accepted a very special birthday present from an old radio friend, Ber van Dongeren PA0DON: the Japanese portable transmitter-receiver pictured in Photo A.

The radio carries a wiring diagram on the inside of the lid (Photo B), but how it was used remained obscure until additional information was provided by Akira Kobayashi JA1JIX. The type number of the radio is 94-6. It was meant for use by the infantry, but found a variety of applications due to its simple operation. Communication distance is given as 2 kilometers.

Frequency is continuously variable in three subbands between 25 and 45.5 MHz. Power during transmission came from a hand-cranked generator, providing 3 volts at 0.35 Amps and 135 volts at 30 milliamps. On receive, power came from batteries for 3 and 135 volts. The antenna was an L-type: 1.4m horizontal and 0.65m vertical.

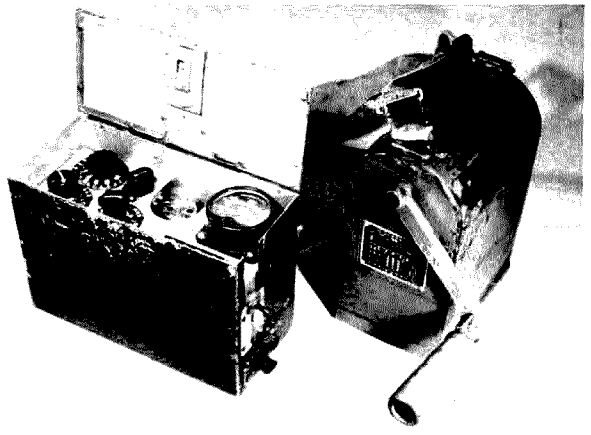

Photo A. Japanese WWII transceiver with hand-cranked generator used when transmitting.

Someone who can read Japanese characters told me that the engraving on the lid says the radio was manufactured by Takanashi in June, 1940. In red characters it says "Secret."

As compared to the sophistication of the modern Japanese sets that dominate the market, the model 94 radio is simplicity itself. There is only one tube, a double triode. The circuit is one that was very popular with amateurs for 56-MHz work in the early thirties. Indeed, the circuit could have been taken straight from *QST* or an *ARRL Handbook* of that period. As a receiver, one triode is a superregenerative detector and the other an audio amplifier. On transmission the first triode becomes a self-excited one-stage transmitter, anode-

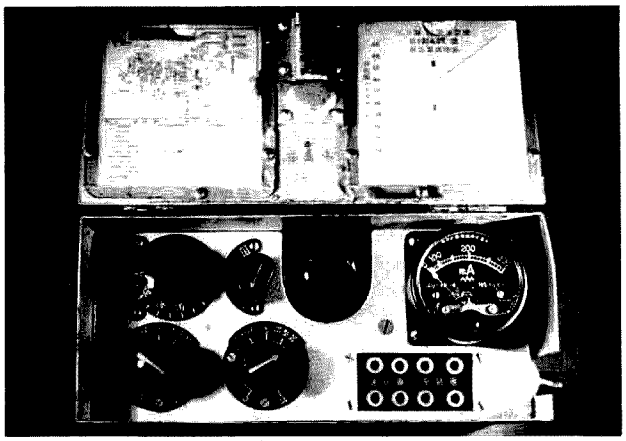

Photo B. Top view of the radio. Inside the lid are the circuit diagram and frequency calibration curves for the three ranges. On the radio, top row left to right: tuning capacitor C5 (see Fig. 4), frequency range switch S1, top of the tube, and antenna-current meter. Bottom: filament-current control R2, variable grid leak R1, and jacks for two handsets.

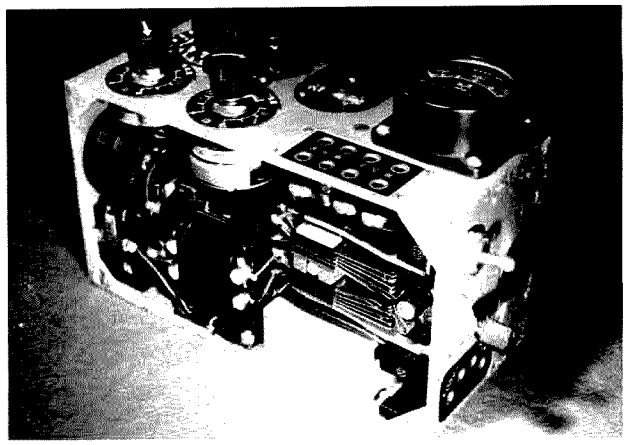

Photo C. At the right center, transmit/receive switch S2; above it, switch S3 to interrupt the microphone circuit when using telegraphy. Behind S2, the Morse "key" can be seen. At the bottom, the cable to the generator is plugged in. Inside the radio, transformer T1 is fastened to the bottom. Microphone transformer T2 is in a screened box below S2. The two round coils below filament-control R3 are L4 and L5, the tuning coils for the quenching oscillation.

modulated by the second triode.

Older readers no doubt will remember the superregenerative receiver or "rushbox." But to the younger generation this electronic marvel may be new. So we start with an explanation of this remarkable type of receiver, invented by that American genius Major E. H. Armstrong, who presented the system in 1922. (Armstrong also gave the world the superheterodyne receiver and the system of frequency modulation for VHF broadcasting!)

The Rushbox Explained

As mentioned, the superregenerative receiver was very popular for reception on VHF and UHF in the early thirties. To explain the principle, I therefore quote the *ARRL Radio Amateur's Handbook* of 1936. Fig. 1 was taken from that source.

First, a "normal" triode with a grid detection and regeneration (positive rf feedback) is explained. The *Handbook* then carries on as follows:

"The limit to which regenerative amplification can be carried is the point at which the tube starts to oscillate, because when oscillations commence, further regenerative amplification ceases. To overcome this limitation and give still greater amplification, the superregenerative *circuit has been devised. Essentially, the superregenerative detector is similar to the ordinary regenerative type but with a low, but super-audible (above audibility) signal introduced in such a way as to vary the detector's operating point at a uniform rate. As a consequence of the introduction of this* quench *or* interruption frequency *the detector can oscillate at the signal frequency only when the operating point is in a region suitable for the production of oscillations. Because the oscillations are constantly being interrupted, the signal can build up to relative tremendous proportions, and the superregenerative detector therefore is extremely sensitive. An elementary form of a superregenerative circuit is shown in [the illustration]. Superregeneration is relatively difficult to attain at ordinary frequencies, and does not possess the property of discriminating between signals of different frequencies characteristic of other types of detectors — in other words, the selectivity is poor. For this reason the superregenerative circuit finds its chief field in the reception of ultra-high-frequency signals, for which purpose it has proved to be eminently successful."*

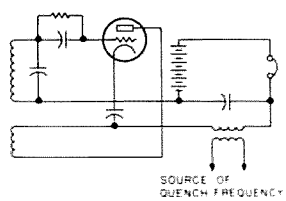

Fig. 1. An elementary superregenerative circuit as shown in the ARRL Radio Amateur's Handbook *of 1936.*

We can go a bit further into the theory by looking at Fig. 2. Here is shown how the signal in the tuned circuit grows exponentially from a starting voltage (V_{in}) to a maximum voltage (V_{max}). V_{max} depends on the anode voltage and maximum anode current the circuit allows to flow. When the voltage in the tuned circuit is higher at the moment the quenching signal makes the detector oscillate, the V_{max} level is reached sooner, as shown in Fig. 2 for a starting

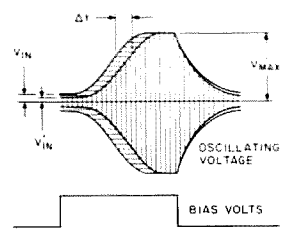

Fig. 2. Oscillating voltages in the superregenerative receiver ensuing from two starting levels, V_{in} and V'_{in} respectively, and finally building up to the same voltage, V_{max}. Lower section: Bias voltage as dependent on time, caused by the quenching oscillator. In reality the voltage is not rectangular but sinusoidal.

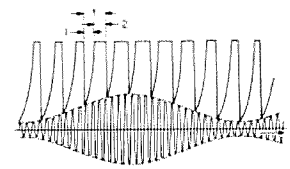

Fig. 3. Received signal, an amplitude-modulated carrier, and the variation of the rectified current through the tube. Starting from the amplitude of the recieved signal, the signal builds up during interval 1 and stays at the maximum level during interval 2. The sum of intervals 1 and 2 is t, the period of the quenching signal.

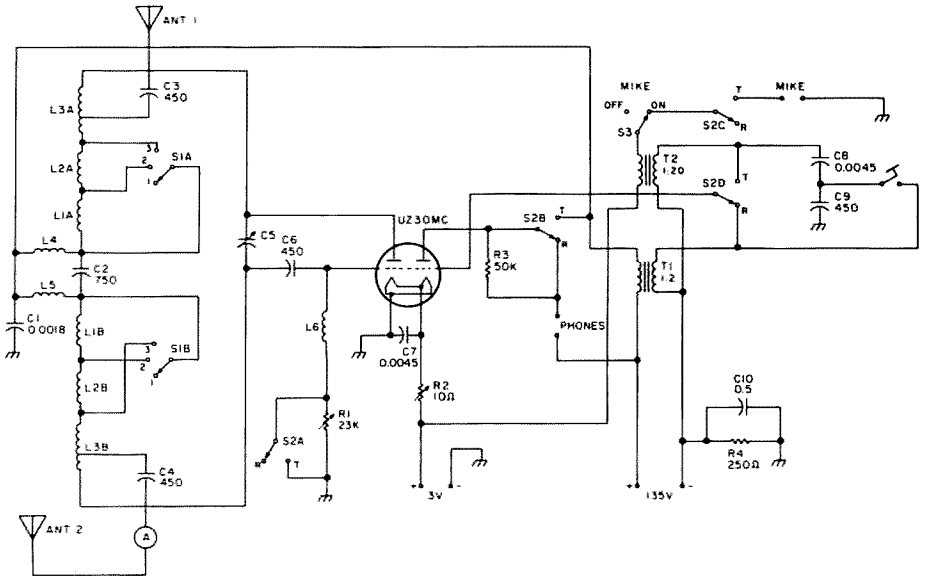

Fig. 4. Circuit diagram of radio type 94-6. The transmit/receive switching is somewhat simplified.

voltage of V'_{in}. The moment the signal decays is also governed by the quenching signal, but independent of the starting signal. So the total surface that is hatched in the illustration varies with the magnitude of the voltage on the tuned circuit at the beginning of each quenching cycle.

As the rf signal is rectified in the detector valve, the hatched area is also a measure for the anode current. This principle is further worked out in Fig. 3, which depicts an amplitude-modulated grid of the detector. The part of the quenching cycle during which oscillations build up has the duration t. So with intervals of t seconds, the anode current builds up as shown in the upper part of Fig. 3.

The buildup follows an exponential law. (For simplicity, the decay is shown as instantaneous at the end of each interval.) So t is divided into a period "1" during which the signal increases and an interval "2" in which it stays constant. It is shown clearly that the area which is a measure for the anode current follows the modulation envelope of the received signal. So in the anode currrent of the superregenerative detector we find the audio that was transmitted. When there is no signal voltage in the tuned circuit there still is thermal noise, which is amplified in the same way as a signal voltage.

This explains the hissing noise that is so characteristic of the superregenerative receiver—lovingly called a rushbox by amateurs of the thirties. As soon as a received signal overrides the noise sufficiently, the hissing sound disappears. In that respect, tuning a rushbox is very similar to tuning a modern FM receiver with the squelch turned off. The fact that circuit noise, perhaps a microvolt or so, is amplified to the full output level of a volt or more in the anode circuit indicates the enormous gain, which can be of the order of a million times. And that in a single stage!

In this respect, the superregenerative receiver is a real marvel, but there is more. The receiver features very good automatic gain control (agc) so that all stations are reproduced at almost the same level. Suppression of impulse noise is excellent, too. This is a very desirable feature on VHF, where automobile ignition noise can be very troublesome. Nowadays every car has good suppression, but before WWII this was more the exception than the rule.

So it seems that the rushbox has only desirable features. Are there no disadvantages then? Sure—selectivity is very poor, as already indicated by the *Handbook*. But even this might be called an advantage: The superregenerative receiver often was used in conjunction with very simple, self-excited, single-stage transmitters. These have very poor frequency stability. So poor that the signals from these transmitters on VHF are mostly unreadable on a superheterodyne receiver. No problem for the rushbox! Its passband is so wide that these signals, which swing all over the place, are coped with easily.

Now that we have refreshed our knowledge on this remarkable invention by Major Armstrong, it is time to return to our Japanese transceiver.

Circuit Analysis

The circuit diagram on the inside of the lid faded so much over the years that I was unsuccessful in making a satisfactory photographic reproduction, so the circuit was redrawn for Fig. 4. (For the sake of clarity, the transmit/receive switching is somewhat simplified.) This switch is visible in Photos A and C.

It is a classic telephone keyswitch with three positions. In the middle position, the set is turned off. The lower position activates the receiver and the upper position activates the transmitter. If both the hand generator and batteries are connected, the transmit/receive switch automatically selects the batteries for reception and the generator for transmission. (These features are deleted in Fig. 4.) S2 is the T/R switch with only two positions shown, T for transmit and R for receive.

The radio is tuned by coils L1, L2, L3, and variable capacitor C5. The frequency range is 25–45.5 MHz, and this is divided into three subbands selected by S1. On the lowest range, all three coils are used; on the middle band, L1 is short-circuited, and on the highest band, both L1 and L2 are short-circuited so that only L3 remains. The coils are three separate ones on formers that can be seen in Photo D. Each coil is divided into equal halves, A and B. Two antennas can be used, indicated as ANT.1 and ANT.2. Perhaps one was meant as an antenna and the other as a counterpoise? A thermocouple ammeter indicates current in ANT.2.

Let us now look at the circuit when the radio is used as a superregenerative receiver. S2 is in position R. The left triode is the detector. C6 is the grid capacitor and R1 is the variable grid leak. But where is the quenching signal coming from? From the same triode, playing a double role. It oscillates at the receive frequency and the quenching frequency at the same time!

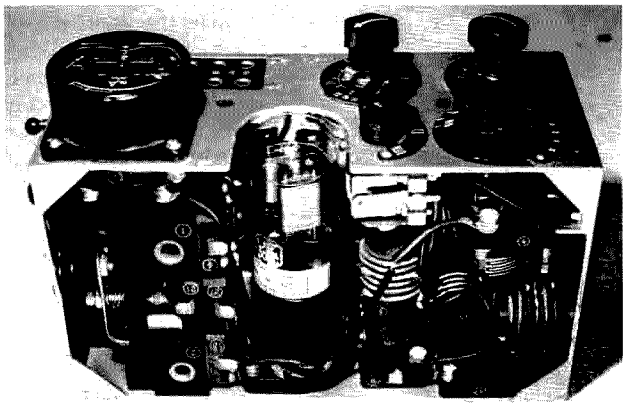

Photo D. At the right, tuning capacitor C5, and around it coils L1, L2, and L3. Left of the tube, the connectors for two antennas (or antenna and counterpoise), and at the extreme left, the Morse key.

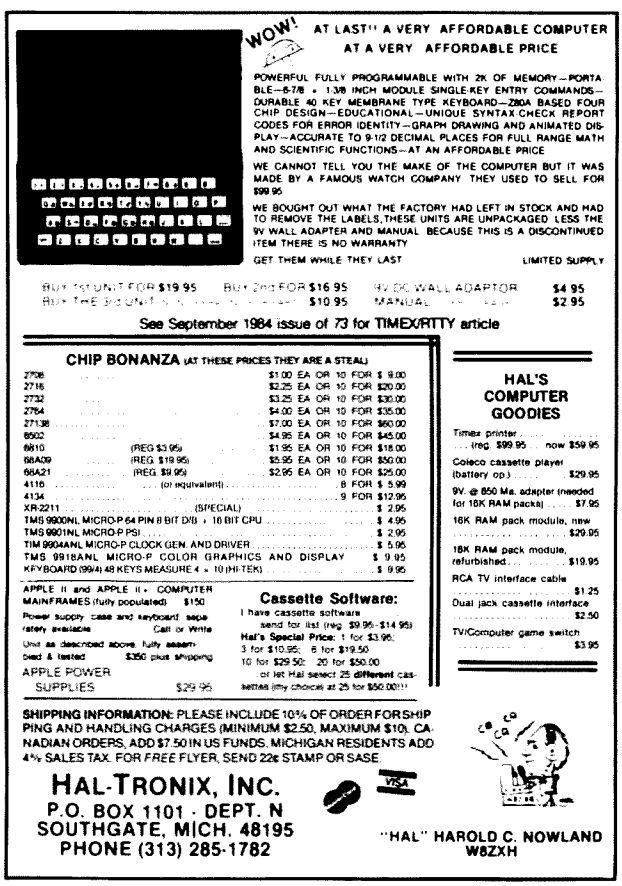
The Japanese designers surely used a clever trick here.

I did not explain why coils L1, L2, and L3 were split into halves. The reason will become clear now. The A and B parts of the coils are connected via C2, which has a very low reactance at rf, so that for the receive frequency the coils can be considered as directly connected. L4 and L5 are closely coupled, as can be seen in Photo C, top left. They act as one coil with a center tap.

C2, L4, and L5 form a tuned circuit. As the center tap is grounded via C1, and grid and anode of the triode are connected to both ends of the circuit, the whole thing forms a Hartley oscillator that happily swings at around 29 kHz (according to my measurement). So that is the quenching signal.

The adjustment for optimum results as a superregenerative detector is always a bit critical, and this one is no exception. Both R1 and filament-current control R2 have to be readjusted when the frequency has been changed more than a little, to obtain the familiar rushing noise. The audio signal in the anode current is taken to the grid of the second triode via T1. The amplified signal goes to the phones. Two of these can be connected to the radio, and they are in the form of handsets that also carry the microphone.

Now we switch to transmit by moving S2 to position T. The left triode becomes a self-excited transmitter, anode-modulated by the triode at the right. S2A short-circuits grid leak R1. So the transmitter tube operates without bias. This is rather unusual, but some reflection brought me the probable explanation. The quench signal has to be stopped on transmission without interrupting the rf oscillation. This is surely effected by short-circuiting R1. Choke L6 has a very low reactance, almost zero Ohms, for the relatively low quench frequency of 29 kHz—so oscillation is impossible. For the transmit frequency, L6 has a high reactance and does not prevent rf oscillation.



The primary winding of T1 now becomes the modulating choke; through it flows the anode current of both triodes (Heising modulation). R3 feeds a bit of signal to the phones for sidetone. Switch section S2D connects the grid of the right triode to microphone transformer T2. The microphone is of the carbon type that requires a dc current. This comes from the 3-V battery and flows via the primary winding of T2, switches S3 and S2C, and via the mike back to the battery.

Negative bias for the audio triode is provided by resistor R4, shunted by C10 for audio frequency signals. Return current from the 135-V battery flows through R4 and so provides a voltage that is negative with respect to ground. Instead of telephony, tone-modulated telegraphy could also be used with the radio (mode A2A, formerly A2). For this mode, the microphone circuit is opened by S3 (in Photo C visible above the transmit/receive switch). The Morse "key" is the black, round knob to the right of the transmit/receive switch in that photo. When the key is worked, the key contact connects the secondary of T1 to C8 and C9, as shown in Fig. 4. This causes af feedback and the right triode generates an audio-frequency note that modulates the transmitter.

Mechanical Construction

The radio is built like the proverbial battleship. As the pictures show, every component is bolted to the frame. Each part carries a number that is also used in the circuit diagram and the parts list on the inside of the lid. Obviously, the designers had servicing very much in mind.

The radio slides into a metal box. How this was carried is not clear, but most likely it was in a canvas cover with the necessary straps for slinging it over the shoulder or fastening to the soldier's belt. As Photo A shows, the generator has a canvas strap. Not shown are pairs of metal hooks that slide outwards at the bottom of the generator. These obviously are meant for hooking the machine to the belt—one pair for the right-handed soldier, the other for the left-handed one. Cranking the generator is not an easy job—so transmissions will be kept brief! ■

Halt That Hum!

That annoying ac hum is robbing you of pleasure. Fix it in an hour with WA4WDL's seven-piece filter.

Believe it or not, everybody does not use solid-state, twelve-volt-compatible equipment even in these modern times. I have an old surplus ARB receiver that I use to listen to the short-wave bands. I especially enjoy *The World Service* of the BBC. The receiver has vacuum tubes, and I know several other SWLs/hams who still use vacuum-tube receivers for similar entertainment. Recently, I got bitten by the RTTY bug and began looking at TU (terminal unit) designs.

The first thing I did was to look at the audio output from the receiver to determine such things as noise level, signal levels, and so on. My biggest surprise was the hum level; it was almost as large as the audio signals. Apparently, my poor low-frequency hearing response and the poor low-frequency response of the four-inch speaker combined to reduce the hum to an acceptable level. A couple of other tube-type receivers were checked. The hum level ranged from my high to about one-tenth the normal audio level.

Once we were all aware of the problem, the hum became unbearable—ignorance is bliss! Fine, all you need to do is increase the high-voltage filter capacitors. This was considered easy until after I had clipped in 200 microfarads to get the hum down to a reasonable level. There had to be a better way. The solution was to build an electronic hum eliminator.

The hum eliminator works like a poor man's voltage regulator. A normal series pass regulator, as in Fig. 1(a), consists of a series pass transistor and a reference voltage. The transistor operates as an emitter follower and the output voltage is simply the reference voltage minus one base-to-emitter voltage drop. The hum eliminator replaces the reference voltage with a resistive voltage divider and a filter capacitor; see Fig. 1(b).

The output voltage is now equal to the input voltage times R2/(R1 + R2). The base-to-emitter drop is ignored. So what good is it? The answer lies in the addition of the capacitor. Without the capacitor, the output voltage would follow the input voltage and the percent of ripple present would not be changed. The capacitor removes the ripple from the base voltage and thereby from the output.

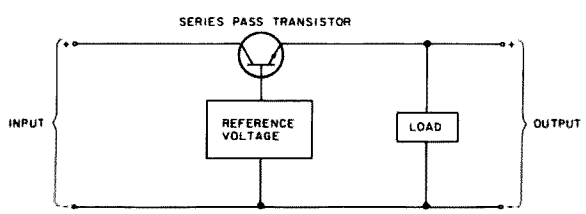

Fig. 1(a). Simplified series voltage regulator.

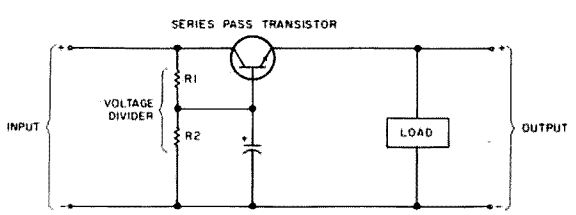

Fig. 1(b). Simplified hum-eliminator circuit.

Q1	SEE TEXT	SERIES PASS TRANSISTOR
C2	.01, 600V	BYPASS (OPTIONAL, SEE TEXT)

Fig. 2. Schematic of the hum eliminator.

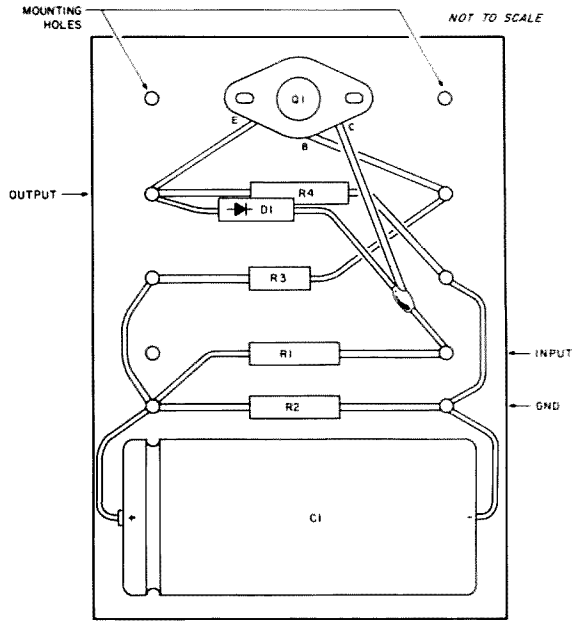

Fig. 3. Pictorial layout of the hum eliminator.

The success of this circuit relies on the difference in time constants in the power supply and the hum-eliminator base circuit. The receiver power supply has a dynamic impedance of about 400 Ohms. The impedance seen at the base of the transistor is roughly R1 in parallel with R2. If we make the parallel combination of R1 and R2 about 10,000 Ohms, the base filter capacitor is 25 times more effective than the same capacitor placed across the input.

Not bad, huh? But this is not free. The output voltage is less with the hum eliminator due to the division ratio of R1 and R2. R1 and R2 should be chosen so that the final output level is less than the input voltage minus the ripple. Otherwise, the series pass transistor will be reverse biased and possibly destroyed.

The actual circuit used is shown in Fig. 2. Note that it is slightly more complicated than that shown in Fig. 1(b). First, a diode has been added across the series pass transistor to prevent reverse biasing. Second, a 270-Ohm resistor has been added to the transistor base circuit. The resistor eliminates parasitic oscillations from the otherwise common base amplifier formed by the addition of the filter capacitor. R1 and R2 were chosen to produce a 25-27-volt drop across the transistor. Since the input ripple was only 10 volts under load, the drop is sufficient. The output ripple is now less than .05 volts and the hum on the audio output is not discernible on my scope or with my ears.

The output transistor should be rated for at least one and a half times the no-load input voltage. Also, the transistor must dissipate the peak current through it times the peak voltage across it. For my receiver, this works out to be 27 volts times 60 milliamps, or 1.62 Watts. I used a 2N4063 because it was available and mounted it on a small heat sink.

C2 is optional and was not needed for every unit. It prevents oscillation when the output leads are excessively long. It is cheap, and eventually I added one to each of my units.

The units were constructed on small terminal boards with staked terminals. Fig. 3 is a pictorial layout of the circuit before C2 was added. Photo A shows two units, one with the heat sink installed and one with the

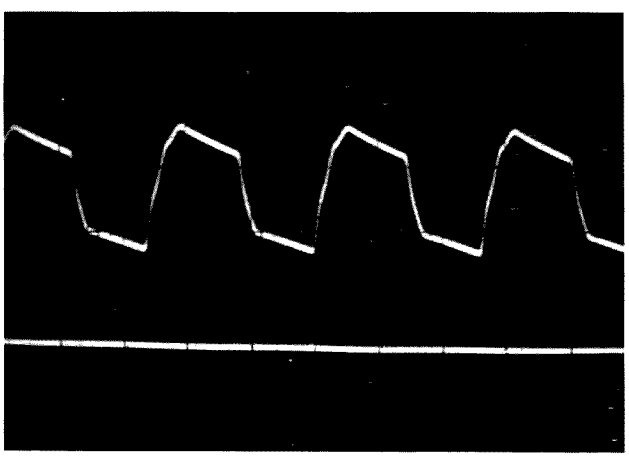

Photo B. Ripple reduction.

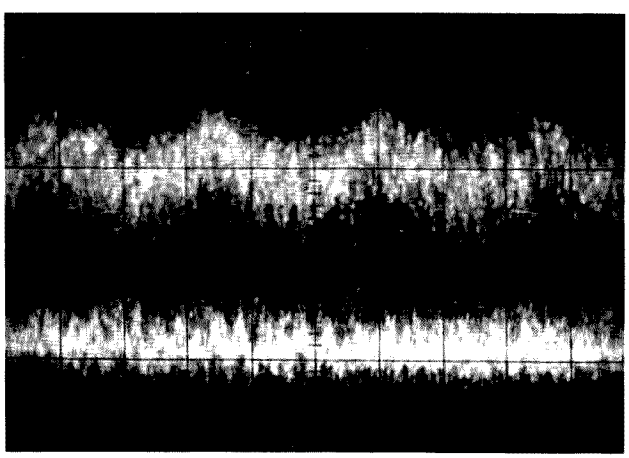

Photo C. Hum reduction, high volume.

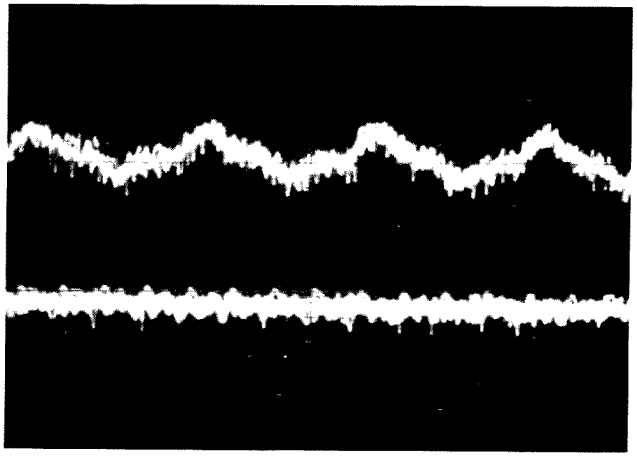

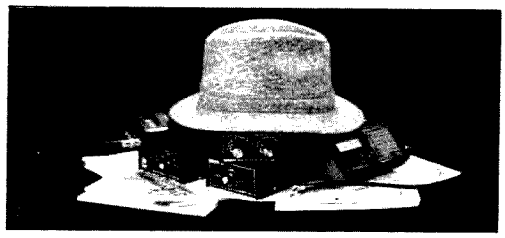

Photo D. Hum reduction, low volume.

heat sink removed to provide a better view. The scope waveform photos show the improvement with this circuit. Photo B shows the ripple reduction. The upper trace, 5 V per cm, was the original ripple level. The lower trace, also 5 V per cm, is the present ripple level. Photos C and D show the hum reduction on the audio output for high and low volume outputs. In each photograph, the upper trace is the before case and the lower trace is the present case.

Now I can go back to looking at TU designs, and soon, hopefully, I will be copying RTTY signals as well as enjoying listening to the BBC with a much improved receiver. ■

We Can't Keep It Under Our Hat...

So many people have discovered our products and publications that we simple can't hide our success any longer. In fact, our commitment to quality merchandise and personalized service has made us one of the worst-kept secrets in communications monitoring.

Explains Ingrid:
"I guess we're just very easy to get to know . . ."

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.

• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.

• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

Faster Than A Patch, It's Speed Dialer

Dial home while driving by simply pushing a single button on the microphone.

Craig Crichton K7UKW
2540 East 12th Street
The Dalles OR 97058

It's Friday afternoon. You're caught in heavy rush-hour traffic. You're going to be late getting home. It would be nice to punch up the patch and advise your wife to adjust dinner time, but do you dare risk dialing in this traffic? Sure! If your rig is equipped with this speed-dial circuit, your eyes never have to leave the road. This article describes circuitry which allows a telephone number to be dialed at high speed by simply pushing a single button on the microphone.

Most hams that operate FM mobile are sooner or later faced with a dilemma—we feel the need (or urge) to use the autopatch while driving. The need is not urgent enough to pull off the freeway or busy street and park, and trying to manipulate a DTMF pad while driving is certainly not worth the risk. And yet, it really would be nice to make that call. I have found myself in this situation many times. This was the reason behind the development of this speed-dial circuit.

There is another benefit gained from using this speed-dial circuit. When the dial button is pushed, the phone number is transmitted at a rather fast rate. The entire seven-digit sequence takes only about one second. This means that each burst of tones lasts only about 65 to 70 milliseconds (there is a silent space between tones). The shorter the burst length, the lower

Photo A. The speed-dial switch mounts on the side of the microphone near the area where the remote volume control used to be. A protection ring around the dial button eliminates any accidental dialing sequences while handling the microphone.

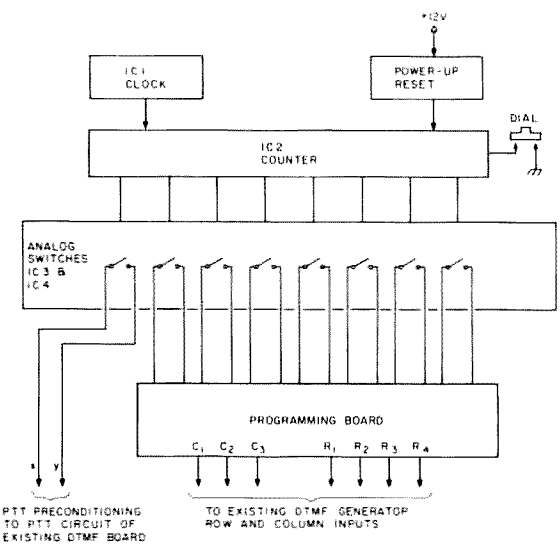

Fig.1. Block diagram of the speed-dial circuit.

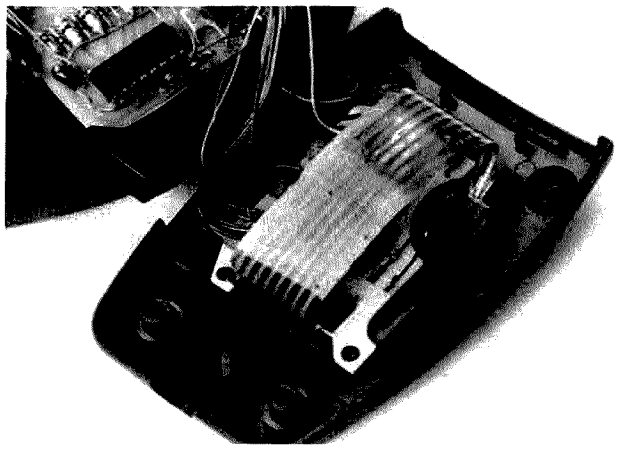

Photo B. In the newer-style microphone (Model PCM-369), capacitor C3 must be changed to a physically smaller tantalum type. Leave its leads long and let it hang over the edge of the board. The older-style PCM-2000 microphone does not need this change.

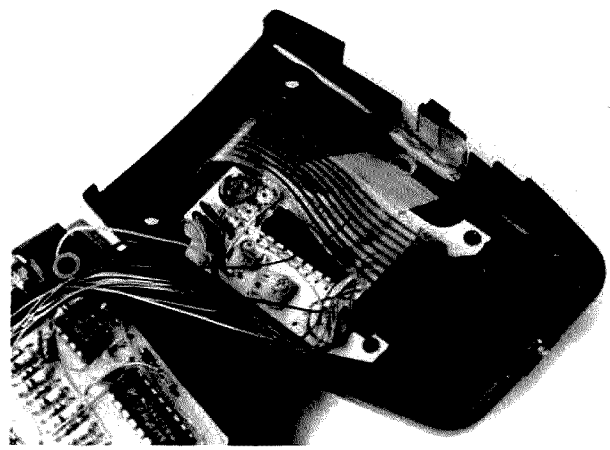

Photo C. In the PCM-369 microphone, the row-and-column leads are connected to the existing solder pins of the plastic bus connector. Route the wires underneath the flat printed-bus cable. Be careful not to burn or melt this printed bus or the connector when soldering in this cramped area.

the probability that rf flutter or "picket-fencing" will cause the telephone equipment to see a double digit. Hence, this speed-dialed number tends to be more accurate than a hand-dialed number lasting hundreds of milliseconds per digit

Limitations

Unfortunately, in order to fit the parts inside the already-stuffed microphone case, certain sacrifices had to be made. There just wasn't enough room for memory chips and their associated parts, so this dialer can hold only one phone number—presumably your home phone, or one that you call regularly. This number is programmed with tiny wire jumpers and is changeable in about ten minutes with a soldering iron. An advantage of this type of "memory," in addition to saving space, is that it is guaranteed not to forget when powered down!

A preconditioner for the PTT would have been nice—a circuit that brings up the transmitter and gets the squelch open on the repeater receiver before the phone number is dialed. Again, space limitations won out over bells and whistles, and because of that, I recommend that you squeeze the PTT bar just prior to pushing the dial switch. I did design in *some* PTT preconditioning, using what limited space I had. The circuitry keys the transmitter about 200 milliseconds prior to the actual dial sequence. Sometimes, however, that is still not quite enough time to bring up the transmitter and open the receiver squelch circuits in time to hear the first digit dialed. As a general rule I would recommend that the PTT bar be squeezed first, just to be safe. This is really much easier to do than it sounds, and can be done quite nicely with just one hand while leaving your eyes on the road and traffic.

This circuit was designed and physically tailored to fit inside my Azden DTMF microphone. However, the circuit is electrically compatible with any DTMF encoder using row-and-column inputs. This includes virtually all of the current encoder circuitry on the market today. If you happen to own an Azden microphone, then you're home free, as I have included a full-size printed-circuit-board layout for this project which will fit into either of the Azden microphones supplied with their earlier transceivers.

It is important to point out that although this article is concerned with mounting circuitry inside a microphone, this is only necessary when the DTMF encoder and touch pad are also mounted in the microphone. The speed-dial circuit must be installed where it has access to the row-and-column inputs of the DTMF encoder chip. In cases where the touch pad is panel-mounted on the radio, the speed-dial circuit would be installed inside the transceiver.

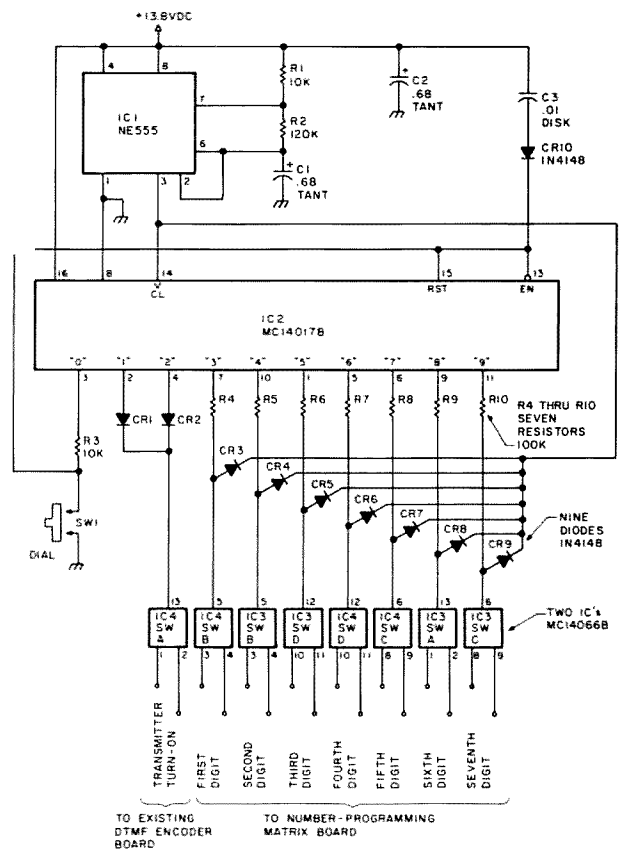

Fig. 2. Schematic of the speed-dial circuit.

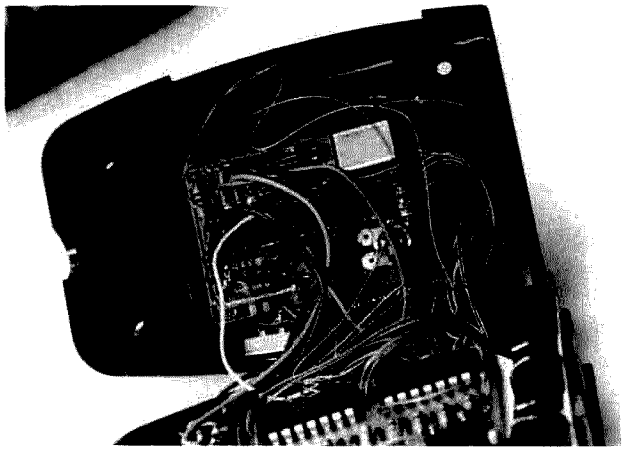

Photo D. In the older-style PCM-2000 microphone, the row-and-column leads are soldered to existing PC pads on the end of the DTMF board. The crystal must be bent up slightly while soldering. Use just a small amount of heat and do not disturb the existing wires which are poking through these pads from below the board.

I have installed this circuit inside two different Azden microphones. One was supplied with the Azden PCS-2000, and the other was supplied with the PCS-3000. These two microphones are physically the same basic unit. Note that Azden radios having serial numbers prior to 53752 require microphones with a battery inside. Because of the limited space in this case, the circuit will probably not fit inside that microphone without changing the physical layout of the parts. I have not attempted to install this circuit in one of those early microphones.

One of the microphones I did modify uses a DTMF encoder, model CSTTK-1, made by Communications Electronics Specialties, Inc. The encoder comes fully assembled in a replacement back for the microphone, and uses a chip, part number S2559C, made by American Micro-Systems, Inc. In general, if your Azden transceiver is a PCS-2000, you will have this type of microphone.

The other microphone I modified included the DTMF generator as a kit (included in the purchase price of the Azden PCS-3000). This unit has a differently-shaped encoder board, a smaller touch pad, and uses a chip made by Mostek, part number MK5087N. The front of this microphone is labeled PCM-369. In general, if your Azden transceiver is a PCS-3000, you will have this type of microphone.

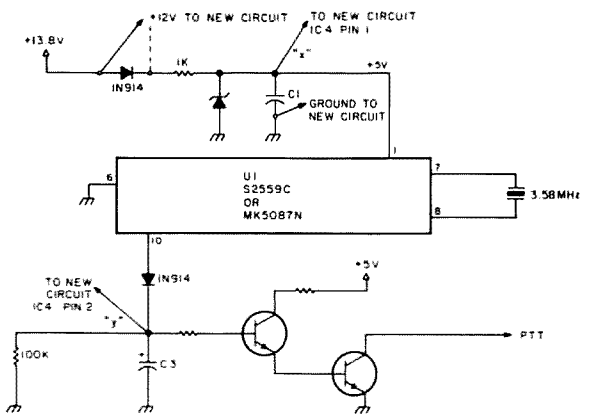

Fig. 3. Partial schematic of the existing DTMF encoder showing points of connection to the new circuit.

Functional Description

Briefly, this circuit consists of a decade counter driving a set of eight isolated switches in sequence, as shown in Fig. 1. Each switch connects a row to a column on the DTMF generator, just as the actual touch-pad switch does when the operator presses it. These switches are normally all off and the counter is in a reset or hold state. When the dial switch is pressed, the counter sweeps through its sequence, turning each switch on, then off. As each switch connects a row to a column input, a pair of tones corresponding to that digit is generated and transmitted just as if the proper switches on the touch pad had been pressed.

Fig. 2 shows the schematic of the speed dialer. IC1 supplies the clock signal for IC2, a 5-stage divide-by-10 Johnson counter with 10 decoded outputs. As IC2 counts, each of its ten outputs goes high sequentially, starting at pin 3 and going on through pin 11, and then back to pin 3. When IC2 is reset (by pin 15), pin 3 is forced high immediately and all other outputs are forced low.

On power-up, C3 and CR10 pass a positive pulse to pin 15, which resets the counter. Pin 3 immediately goes high and is fed back to pin 15 via R3 to hold it in the reset state. This high is also fed to pin 13, which holds the counter disabled from the free-running clock at pin 14. This is the state that the counter remains in until called on to dial a number.

When the dial switch is momentarily pressed, IC2 pins 13 and 15 are pulled low. This enables the clock, and the counter begins its sequential pulse train. As soon as the first clock pulse is registered, pin 3 goes low and the dial switch can be released. This all happens within about 100 milliseconds. Thus the chip is held enabled and counting by its own pin-3 output (low) until it goes through all ten outputs and cycles back around to bring pin 3 high again. At that time, this high disables the counter and locks the chip in its "hold" mode again.

Now let's see what happens as the counter sequentially outputs highs. Each of these outputs is fed in turn to either IC3 or IC4. These chips contain MOSFET bilateral switches. Each one of these switches is like a tiny relay with normally-open switch contacts. When the input goes high, the switch closes. These switches are really very good—opened they have less than 200 picoamperes leakage, and closed resistance is typically less than 80 Ohms.

The first output, pin 2, is fed via CR1 to switch A. This switch is part of the PTT preconditioning mentioned earlier. The output is connected to the existing DTMF board, supplying +5 volts to the base of the PTT driver transistor. This connection is shown as points X and Y in Fig. 3. When the switch closes, it keys up the PTT

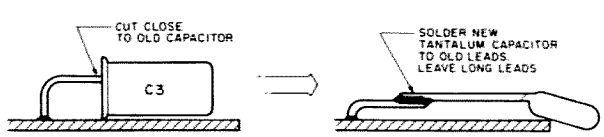

Fig. 4. For the PCM-369 microphone, replace C3 with a smaller tantalum capacitor. Leave long leads and let it hang over the edge of the encoder board.

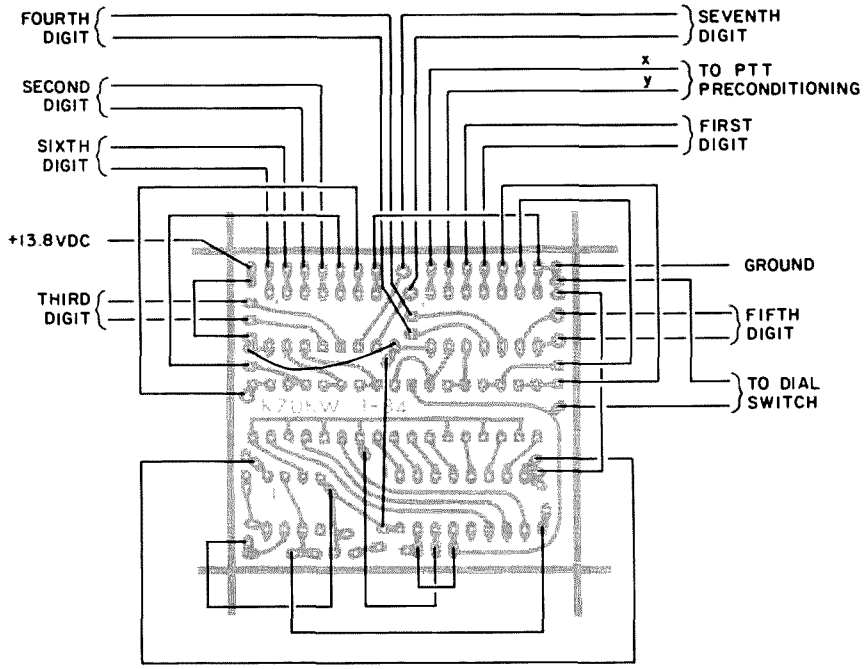

Fig. 5. Layout of the main board, shown from the foil side, detailing jumpers and interconnect wires.

and charges the PTT holding capacitor (C3, Fig. 3), which holds the PTT on until the next high from IC2 pin 4. This high from IC2 pin 4 is also fed to IC4 switch A, via CR2, which keeps the PTT on and again charges the holding capacitor. The net effect of all this is to give the transmitter a 200-millisecond head start before the tones are actually generated. This helps get squelch circuits opened prior to the actual dialing of the number.

The rest of the operation is very straightforward. As each output goes high, its associated switch is closed. This switch is tied across the row-and-column input for that digit. When the switch closes, the tones are generated. After the last digit is generated, the counter rolls around to pin 3 again, where it stops itself and holds, waiting for the next dialing sequence.

Resistors R4 through R10 and CR3 through CR9 form logical AND gates at the input to each of the seven bilateral switches. Here the sequential highs from the counter are ANDed with the free-running clock to produce first a dual tone and then a quiet period for each digit produced. The reason for this is so the telephone equipment can distinguish between two sequential identical digits. For example, in a phone number such as 296-5114, if there were no quiet period between digits, the phone equipment would only see 296-514, with the "1" being twice as long as the other digits. Telephone equipment specifications require certain minimum-timing sequences and inter-digit pauses, and the circuitry operates within these constraints.

Some readers may wonder why I used resistors and diodes to form the AND gates instead of an integrated circuit like the CD4081. Although it would have taken up no more room on the board, the PC layout would have become much more complicated due to the input/output-pin layouts on these chips.

The phone numbers are actually developed on the little programming board, where each bilateral switch closure is jumpered to the proper row-and-column input for that particular digit in the sequence. Fig. 8 shows the board programmed for a sample number.

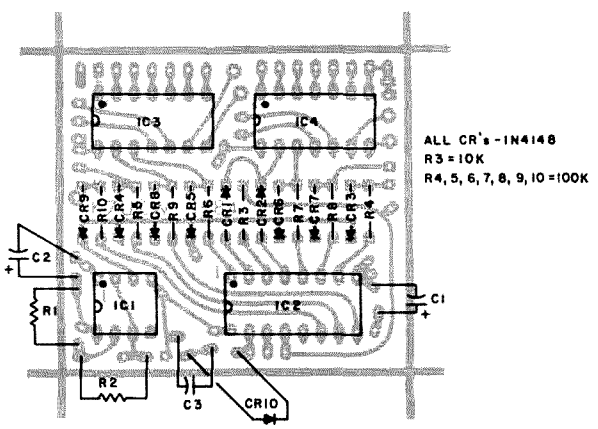

Fig. 6. Parts placement guide as seen through the board.

Mounting Considerations

In order to make this new board fit inside the Azden microphone, a few existing conveniences have to be given up. The remote volume control (and squelch control if your microphone has it) must be removed. I don't think of this as a great inconvenience because I never use them anyway. In fact, I had already traded my remote-squelch control for a reverse switch to allow monitoring of the repeater input momentarily. I kept that switch and removed the red volume knob, wrapped the volume pot in tape, and stuffed it down under the reversing switch where it was out of the way.

On the newer microphone (the one labeled PCM-369) a change must be made to the DTMF generator board. Capacitor C3, the inter-digit PTT hold-timing capacitor, must be changed from a rather fat electrolytic to a slender tantalum type and, at the same time, moved so that it hangs over the edge of the board. See Fig. 4 and Photo B. This gives us nearly an eighth of an inch more room in the cavity between the DTMF encoder board and the microphone element, allowing the new speed-dial board to fit snugly within this space.

Due to obvious space requirements, I recommend using printed-circuit-board techniques. I used a single-sided board layout rather than a double-sided layout for two reasons. Single-sided boards are much easier to make masks for, and most hobbyists shy away from double-sided work because of the extra time and effort needed for proper registration. Since I planned to

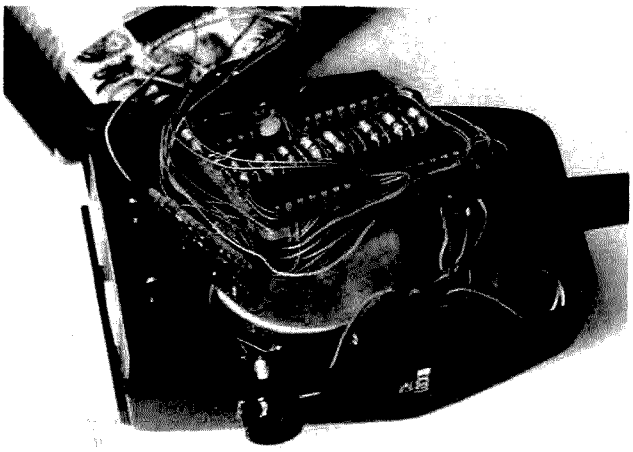

Photo E. Packing it all inside the microphone case looks impossible at first glance. The little program board slips vertically between the mike element and the two up/down switches; cover the solder side with electrical tape first. The main board then overlaps it and lies flat against the mike element, insulated with Kraft paper.

share this with other hams, I opted for the simplest technique from a construction standpoint. In the case of a small circuit like this, being constructed at home using hobby techniques, a single-sided layout using even a large number of jumpers is usually preferred over double-sided layouts.

Constructing the Circuit

When you have etched, cleaned, and drilled your boards, there are a few considerations to keep in mind while you stuff them with parts and connect the jumper wires. Use reasonably small wire for all jumpers and connecting leads. Space inside the microphone is at a premium and the smaller the wire, the easier it will be to get the case halves back together after adding this new circuit. I used AWG 30 Kynar wire-wrap wire for everything. It is very thin and the insulation is tough.

Start by installing all the resistors and diodes in the middle of the main board. Hole spacing is tight, but quarter-Watt resistors will just fit if their leads are bent tightly down against the ends of the resistor body. Pay attention to Fig. 6 and get the diodes in correctly—there are two diodes near the center of the board that are reversed from the others. Next, install all the jumpers on the main board. Fig. 5 shows these jumpers along with the other interconnect wires. Be sure to route these jumpers around the areas where the four ICs will be placed. We want the ICs to fit tightly against the board, not on top of a wire. Note that Figs. 5 and 6 are viewed from the solder side of the board. It was considered easier to locate holes from this side of the board since the top side is not silk-screened.

After soldering the connections, be careful when snipping *off* the wires on the bottom side of the board. The wire ends must be cut very short and flush to the board. If big blobs of solder and wire are left, the board will be too thick to fit inside the microphone. Be very careful to leave no sharp points either, because these could cause shorts.

Now install all of the other parts except the ICs. Fig. 6 shows their locations. Refer to the photos to bend the three capacitors. Their orientation is not critical, but the parts do have to lie flat against the board to keep the package as thin as possible.

Now it's time to mount the push-button switch on the microphone. Refer to Photos A, E, and F for the location. I found it much easier to attach two eight-inch leads to the switch before I mounted it—the excess can be trimmed off when soldering the wires to the board. Photos A and E show a raised cylinder around the actual push-button. I added this to prevent any possibility of an unintentional dialing sequence. Do not add this yet; its construction and mounting will be dealt with later.

The next step is to program (jumper) the little memory board. These jumpers can be put in last, but it is easier if the memory board is not yet connected to the main board. Again, I used AWG 30 Kynar wire. Refer to Fig. 7 and Table 1 for the placement of the program jumpers. Fig. 8 is an example; it is shown programmed for the phone number 296-1234.

When the memory board is programmed, it must be attached to the main board by the digit-enable wires. These connections are shown in Figs. 5 and 7. When cutting the wires, be sure to leave enough length to position the two boards as shown in the photos. The little telephone-number program board will mount vertically, underneath the end of the main board. The main board just overlaps the little board.

The last connections to this little board are the row-and-column inputs from the existing DTMF board. Refer to Fig. 9 if you have the older-style microphone (Azden PCM-2000). Refer to Fig. 10 if you have the newer-style microphone (Azden PCM-369). Fig. 7 shows the connections to the program board. These leads should be left long enough to allow the case halves to open flat for servicing, but not any

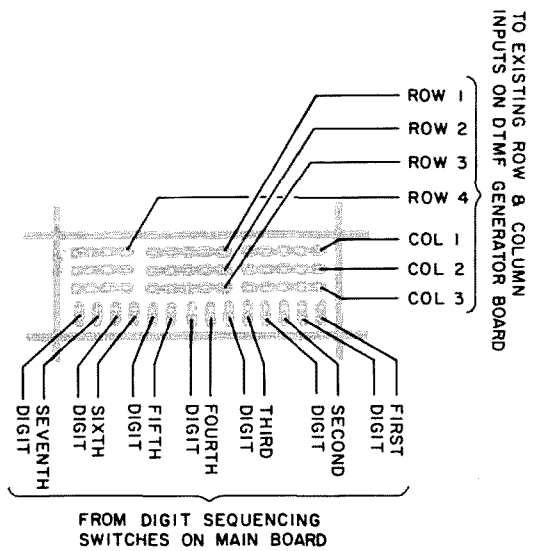

Fig. 7. Solder side of the program board, showing interconnect routing.

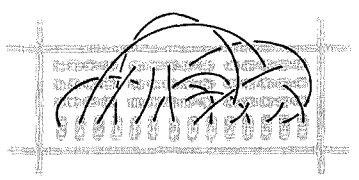

Fig. 8. A programmed memory board. The number is 296-1234.

longer than necessary. It all has to fit inside eventually!

There should now be only six holes left on the main board without wires in them—two for the dial switch, two for +Vcc and ground, and two for the PTT preconditioning circuit. Cut four eight-inch wires. Solder one end of a wire into each of the remaining holes except the dial-switch holes. Refer to Fig. 5. Let the free ends dangle for now.

Cut a piece of electrical tape and cover the solder side of the little memory board. Referring to Photo E, lay the memory board vertically between the microphone element and the up/down switches. The tape-covered solder side should face away from the microphone element. The main board should lie flat against the back of the microphone element, solder side down against the top of the microphone element. You must remove any pieces of sticky-backed foam that were used to keep the microphone element in place.

Fig. 3 shows a portion of the circuit used in the existing DTMF encoder. The circuit is *similar for* both models of Azden. Fig. 3 indicates electrical connections for the four wires previously mentioned. Depending on your type of microphone, Figs. 9 and 10 show the actual physical connections indicated in Fig. 3. Refer to the correct figure and Photos B, C, and D, and connect these four wires. Refer to Fig. 5 and connect the two wires coming from the dial switch.

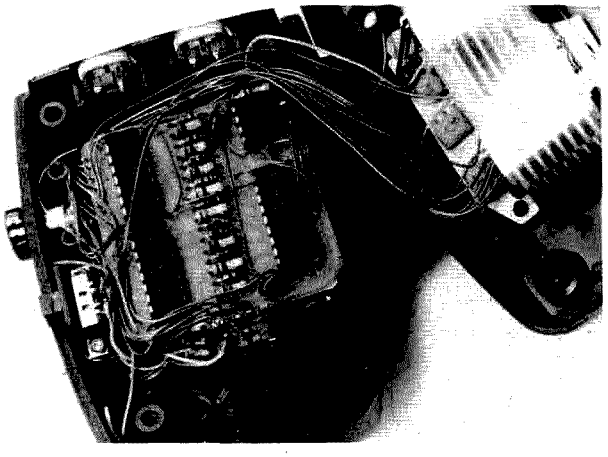

Photo F. When mounting the parts on the printed-circuit board, be sure to orient the three capacitors flat against the board—there is not enough room to allow them to mount vertically. The exact routing of the many connecting wires is not critical.

Refer to Fig. 6 and install the integrated circuits. Be careful not to handle their leads any more than necessary—use standard CMOS precautions. After soldering them in place, be sure to snip off all the sharp tips. Now cut out two pieces of heavy paper (I used index-card stock) just the same size as the main board. Slip one piece under the main board to protect the solder side from touching the microphone element. The other piece goes on top of the main board to protect its parts from touching the existing DTMF board. It might be a good idea to recheck the solder side of the board at this point for any sharp, pointed connections. These connections will work their way through the paper insulation in time and cause malfunctions when they short to the microphone element.

Checking It Out

It is a good idea to check the performance of the circuit before you go to all the effort of assembling the case halves and installing the four retaining screws. The easiest way to check it is to put the transmitter on a seldom-used simplex frequency, connected to a dummy load, and then push the dial button while listening with another receiver. You should hear the seven-digit phone number transmitted at about six to eight digits per second. It should be transmitted only once, unless you hold the dial button down.

If everything seems normal, assemble the case halves together making sure that no wires get pinched in the process. This is a fairly snug fit; it needs just a slight bit of pressure to make the case halves fit completely together. If it requires heavy pressure, or if you feel that you are having to force things, then there is something wrong and you need to check for pinched wires, unclipped solder leads, large blobs of solder on the back, parts not inserted all the way into the board, etc.

Now that the case halves are assembled together, make the on-the-air test again to make sure nothing

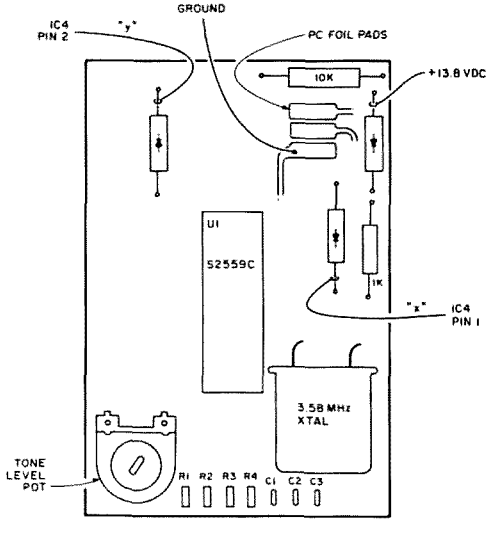

Fig. 9. The PCM-2000 DTMF generator.

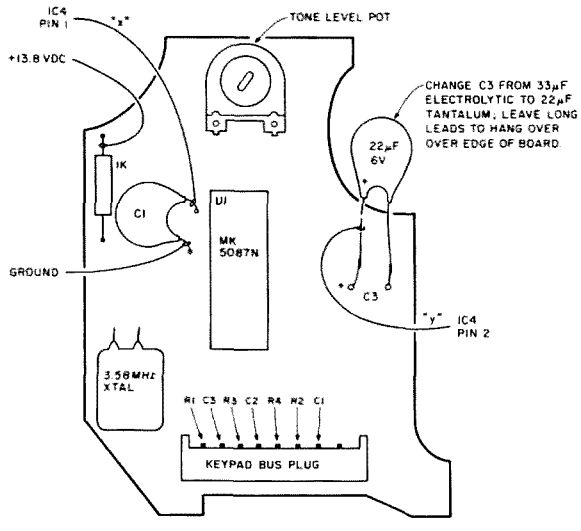

Fig. 10. The PCM-369 DTMF generator.

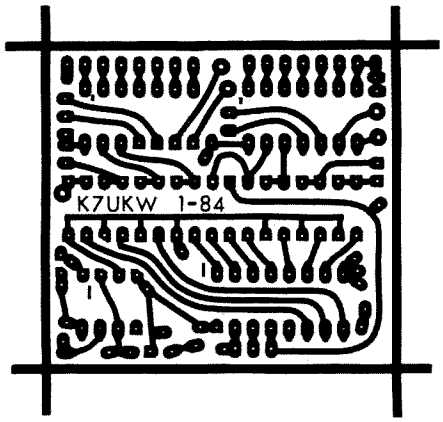

Fig. 11. Circuit pattern, full size, foil side.

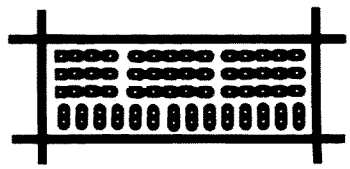

Fig. 12. Program-board pattern, full size, foil side.

got pinched or shorted. If this goes well, make a manual test of all the keys on the keypad. Another very important test to make is to check the power-up reset circuitry, C3 and CR10. Turn off your transceiver but leave the separate monitor receiver on. Now turn on the transceiver connected to the modified microphone. It should come up in the receive mode and should not transmit a string of tone digits. Repeat this several times to assure yourself that the modification will always power up in a standby mode.

The last and most important test is the on-the-air test. Call up your local patch, push the PTT bar, and tap the dial button. Make sure that it dials the number you expected. Repeat several times to be certain that it is consistent.

When you are satisfied that all is working properly, you are ready to put the finishing touches on the project. This consists of attaching a small cylinder about one-quarter inch high around the push-button dial switch. This prevents accidental dialing when reaching for the microphone or holding it in your hands. It will not allow a casual brush to trigger the switch, but an on-target finger tip can still very easily trigger the dial sequence when desired.

To Generate Digit	From Column	To Row
1	C1	R1
2	C2	R1
3	C3	R1
4	C1	R2
5	C2	R2
6	C3	R2
7	C1	R3
8	C2	R3
9	C3	R3
0	C2	R4

Table. 1. Jumper programming connections.

The material for this protection ring can be nearly anything you can imagine. I used a piece cut from the cap of a discarded Flair felt-tipped pen. After sanding the cut edges smooth, mix up some epoxy glue and attach the cylinder to the microphone case around the switch. It helps to rough up the microphone case first with a pin or sandpaper so that the epoxy can stick better. You can experiment with other types of adhesives, but the only thing I've found that will adhere to the plastic in these microphones is the two-part epoxy that you mix individually for each job. After the epoxy hardens, the ring can be painted black to match the rest of the microphone.

In Case of Difficulty

Troubleshooting and correcting problems are not too difficult if you keep in mind how the circuit operates and how it interconnects to the other microphone circuits.

If you have trouble, the first thing to do is to verify your power source. Check for +13 V dc (nominal) at IC1 form pin 8 to pin 1. Also check for +13 V dc from IC2 pin 16 to pin 8, and ICs 3 and 4, pin 14 to pin 7. This verifies the proper placement of the Vcc and ground jumpers on the board, too. I checked both circuits I made for proper operation over a varying voltage source and found them to be reliable from +8 V dc to +17 V dc. This is, of course, a much greater range than one would ever expect from an automobile system, but it perhaps will help eliminate any suspicions of malfunctions due to low (or high) battery voltage.

Check for a constant clock pulse on IC1 pin 3. This should be nominally 10 Hz. This waveform must be present as long as power is applied to the circuit. It should toggle to within at least 10 percent of the supply rails.

If a number is dialed, but it is the wrong number, first check that you can correctly dial the number manually using the built-in touch pad on the microphone. If this works properly every time you try, then the trouble must be in the circuit you have added, not in the DTMF generator or phone patch. Check to make sure that you have wired the digit-switching wires correctly between the main board and the number-program board. Refer to Figs. 5 and 7. Another possiblity is incorrect wiring between the program board and the row-and-column inputs of the existing DTMF chip. Refer to Fig. 7 and either Fig. 9 or Fig. 10 and double check. Of course, you should check the actual number programming on the little board—refer to Figs. 7 and 8, and Table 1.

Note that the telephone company has certain limitations concerning the speed at which we dial, the length of each digit, and the quiet space between each digit. Listen to your burst of digits; it should take about one second to send out all seven digits. If it takes significantly less time, you may be pushing the limits of the telephone company's equipment. Check R2 and C1 for correct values (Fig. 2).

If all these checks turn up nothing, try temporarily tacking a larger capacitor (something like 4 to 10 mF) across C1 on the main circuit board. This will greatly slow down the clock to the counter chip and allow you to follow in detail the digit generation sequence. Perhaps you can spot the trouble at this slower rate. This slower rate will also enable you to probe the output pins of IC2 during the digit sequencing to verify that IC2 is working properly. While listening to the sequence, make sure that there is a quiet period between tones of about the same duration as the tones are on. If not, check very carefully the orientation of all the diodes in the middle of the board. Refer to Fig. 6. Note that two of them are reversed from the others.

If you experience a dial sequence upon power-up, check that CR10 is not in backwards or open. Also make sure C3 is not open. If you can get no dial sequence or only part of a sequence, check that C3 is not

shorted. If the dial sequence runs over and over, suspect a shorted dial switch or connecting wires. This can also be caused by a leaky C3. Make sure the value of R3 is 10k Ohms.

If none of the above exercises seem to have helped, you must get tough and start isolating the board into sections to find where the trouble actually is.

Begin by getting the circuit into a quiescent state (not dialing). If yours already is, skip to the next paragraph. If not, unsolder the jumper wire from pin 14 of IC2. This removes the clock from IC2. Now power up the circuit and momentarily touch a wire from +13 V dc to pin 15 of IC2. This must reset IC2. Pin 3 of IC2 should now be high, and all other digit outputs (pins 2,4,7,10, 1,5,6,9, and 11) should be low.

Now turn on the monitor receiver and listen while performing the following checks. Using a 10k-Ohm resistor with one end tied to +13 V dc, touch the other end to each bilateral-switch control lead one at a time, while listening to the generated tone in the receiver. Using another DTMF generator (or a telephone held to your ear), compare the pitch of the tones and verify that the required tones are correct for each digit. For example, touch the 10k resistor to IC4 pin 5. This should key the transmitter and generate the first digit of your programmed phone number. If everything goes well here, then the program board, the bilateral switch ICs, and the connecting wiring are OK.

You can then proceed backward through the circuit, isolating each chip and verifying if it is doing what it is supposed to do. For example, with a valid clock input to IC2 pin 14, IC2 should count from 0 to 9 on each rising clock pulse. As each output goes high during its count, all other outputs must go low. This can actually be checked with a meter if the clock is slowed down sufficiently with a swamping capacitor as described earlier. When output 0 goes high, this high should be fed around through R3 to pins 15 and 13. This should clamp the chip at reset and disable the clock from any more counting.

All of this troubleshooting advice may seem a little intimidating and, in fact, is probably not really necessary. I have had no trouble at all with either of the circuits that I have built. If good quality parts and reasonable care in construction are used, you should be able to gleefully skip over all this dry, pessimistic troubleshooting information. But if that bug does find its way into your project, its nice to have a little guidance for locating the rascal.

Parts List

C1, C2	0.68-μF, 25-V tantalum	Jameco TM.68/35
C3	0.01-μF, 50-V disc ceramic	Jameco DC.01/50 or RS 272-131
C4*	22-μF, 6-V tantalum	Jameco TM22/6
CR1-CR10	1N4148 or 1N914 diode	Jameco 1N4148 or RS 276-1122
IC1	NE555V	Jameco NE555V or RS 276-1723
IC2	MC14017 or CD4017	Jameco CD4017 or RS 276-2417
IC3, IC4	MC14066 or CD4066	Jameco CD4066 or RS 276-2466
R1, R3	10k, 1/4 Watt, 5%	Jameco 10k-1/4W or RS 271-1335
R2	120k, 1/4 Watt, 5%	Jameco 120k-1/4

Using the Circuit

A good many of the local telephone autopatches in use today are simple, open machines that use a star (*) to bring them up and a pound sign (#) to shut them down. The autopatch for which I designed this circuit works that way, too. In this case, there is truly no reason to ever take one's eyes off the road to use the patch. The star (*) button is easy to find by feel, and a short burst after a proper ID is all that it takes to hear a dial tone. Once the dial tone is verified, a short squeeze on the PTT bar coupled with a fingertip tap on the dial button initiates the dialing sequence. Make sure that you release the PTT bar and dial button after no more than a half second—just a tap is all that it takes. If you hold the button in for more than about one second, you may trigger another burst of dialing. This won't generally bother the telephone equipment, but it sounds rather unprofessional over the air.

When your transceiver returns to the receive mode, you will either hear the phone ringing or a few seconds of clicking and then the ring-back, depending on how modern your local central office is. Our central office has not yet been upgraded to ESS (electronic-switching system) equipment, so all of the DTMF tones we dial have to be slowly converted to rotary-dial pulses before being fed into the phone equipment. That is the reason for the two- or three-second pause before the ring-back is heard. The reason that I mention this is because you normally don't hear it. This is because by the time you have manually pushed all the touch-pad buttons for your call (a relatively slow process), the tone-to-rotary conversion (if required in your exchange) has been nearly completed. When you stop dialing and listen, usually all that you hear is the last few clicks and then a ring-back.

When you dial with this speed-dial circuit, however, the tones are sent out so fast that only the first one or two digits have been converted by the time your receiver kicks back on. Hence you hear a relatively long (three to six seconds depending on the phone number) period of either silence or dialing clicks before the phone begins ringing. I mention this only so those individuals who are not familiar with the phone system won't panic or wonder if they got a wrong number before the phone finally rings.

Of course, when your call is finished, bringing the patch down is just as simple. The pound sign is easily located by feel and a quick jab is all it takes, followed by your call and any necessary logging. This can all be accomplished without ever taking your eyes away from traffic. If your local patch requires a security number to bring it up, rather than a simple star then, of course, this will require a brief glance at the touch pad. But the concentration and viewing required for dialing the actual phone number has been completely removed by this speed-dial circuit. ■

Don't Be A Kamikaze!

The Hara-Kiri Box is an improvement on the suicide cord that's still dangerous, but it's a lot safer than the cord.

Larry C. Ledford KA4J
553-4th Street SE
Cleveland TN 37311

Few hams will admit that they are foolish enough to use a suicide cord—a line cord with two alligator clips that is used to apply 110 volts ac for testing a transformer or motor. While it is very unhandy to properly set up a test jig to apply power for the testing of a component, it is equally unhandy to complete a project only to find that a component is defective or unsuitable (and have to replace it with a component of a different and often larger size).

The use of a suicide cord will tell you if the item is usable, but can kill in the process. You reach over to plug the cord in as one of the leads comes loose, and when you reconnect it, *zap!* your body becomes a conductor between the clip and the concrete floor.

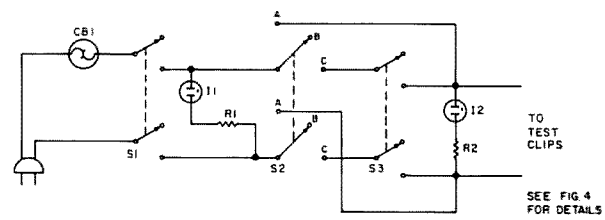
The Hara-Kiri box is an improvement on the suicide cord that still is dangerous, but far safer than the cord. It is a unit that will allow you to apply power to a component momentarily or for extended periods of testing. It is protected from shorts by an automatically-resettable circuit breaker and has two indicator lights to warn if power is on or available. Both sides of the line are switched to protect you. When any two of its three switches are in the Off position, no voltage appears across the test clips or between either of the test clips and ground.

The only exotic component used in the Hara-Kiri box is the circuit breaker. This is a four-for-a-dollar hamfest item which apparently was surplus from a manufacturer of battery chargers. It looks like a large neon bulb. If you can't find one, use a 1-3-Amp fuse and holder.

Construction is standard except for the preparation of the test leads. The end of the zip cord is separated for about three inches with one side cut one inch shorter than the other. This is done so that if the clips should slip off the component under test, they cannot touch each other and cause a short. Due to the flexibility of the wire, they can be brought very close together. Should one clip come undone, the resiliency of the zip cord will spring it away from the other clip. Be sure to use the insulating boots on the alligator clips.

Label the switches as follows:

S1 Mains Off
Mains On
S2 A Steady On
S2 B Off
S2 C Push Switch
S3 Push On
I1 Mains On
I2 Live



Also put a label stating: "Caution! Dangerous Voltge." My box also carries this warning: "Be Careful! Death Is So Permanent."

S1	S2 Position	S3	I1	I2	Ohmmeter Reading
Off	Off (B)	Off	Off	Off	0
On	Off	Off	On	Off	0
On	Steady (A)	Off	On	On	110 V ac
On	Push Switch (C)	Off	On	Off	0
On	Push Switch	On	On	On	110 V ac

Fig. 1.

S1	S2 Position	S3	Ohmmeter Reading
Off	Any	Off	High Ohms
On	B (Off)	Off	High
On	A (Steady On)	Off	Low Ohms
On	C (Push Switch)	Off	High
On	C (Push Switch)	On	Low Ohms

Fig. 2.

Note: all switches shown in the off position.

Fig. 3. Schematic.

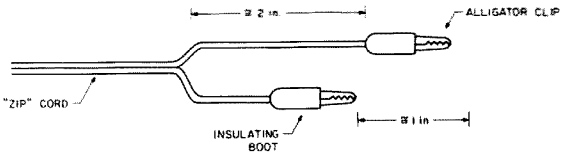


Fig. 4. Preparation of the test leads.

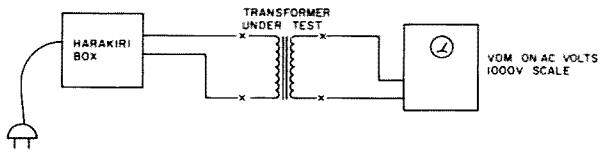

Fig. 5. Setup for using the Hara-Kiri box.

After you have finished wiring the box, it's important to run a series of tests to ensure that the box is safe to use. With the line cord disconnected from 110 V ac, connect the test clips together. Connect a VOM (in the Low Ohms position) across the blades of the line-cord plug. You should refer to Fig. 1 when operating the switches.

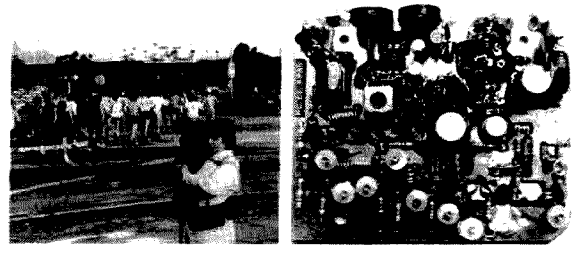
Any departure from the readings in Fig. 1 indicates either a defective switch or miswiring. Correct before continuing. If the readings are OK, then connect the VOM between one of the blades of the plug and one of the test clips. Since we are switching both sides of the line, there is a 50-50 chance that one of the VOM's leads will be connected to the wrong side. So if you can't get an indication on the ohmmeter, move the VOM lead to the other blade. Go through the switch sequences in Fig. 1. Readings should be the same. If they are, move the VOM leads to the other blade and the other VOM lead to the other test lead. Again, repeat the test sequence. If all is normal, then test for leakage between either of the plug blades (test one at a time) and the "bats" of the switches and the case (if you used a metal one). There should be no leakage.

Now give it a smoke test. Set the VOM for a 150-V-ac-or-more scale. Turn S1 off. Connect the test leads to the VOM. Plug the box into 110 V ac. You should have the readings in Fig. 2 on the voltmeter and indicator lights.

Turn S1 and S2 to the Off position. If the box has passed all the tests, it is now safe to use. While it may seem redundant to give this simple circuit this many tests, remember we are working with the one component that we cannot get an exact replacement for should we ruin it—*you!*

Using the Hara-Kiri box is simple and hopefully safe. Let's go through the procedure for testing an unknown transformer, which seems to be the component that I test the most often: Switch S1 (Mains) off. Switch S2 off. Plug the box into 110 V ac. For maximum safety, the box and the transformer should rest on an insulated surface. Connect the primary leads of the transformer to the test leads of the box. These are usually color-coded black. Place the VOM on the 1000-V-ac scale. This will protect the meter if the transformer has a high-voltage secondary.

Connect the VOM test leads to the transformer secondary. The leads of the VOM should have insulated alligator clips. It defeats the purpose of the box for you to hold on to the dangerous part of the circuit while applying power to it. Turn S1 on. I1 should light. Turn S2 to C (Push Switch). Push S3. I2 should light and the VOM should indicate some voltage. Release S3 and move the VOM to a lower scale for easier reading if necessary. Push S3 and note the reading. Release S3 and record the voltage of the secondary. Repeat for any other secondary windings.



For continuous use, switch S2 to the A (Steady On) position. If I1 should go out while testing, then either the transformer is shorted or a short exists across the test leads. The circuit breaker has tripped. Switch S2 to the Off position and wait for the breaker to recycle; when it does, I1 will light up. When you are through using the box, turn S1 and S2 to the Off position.

The name Hara-Kiri is a dark humorous reference to the Japanese custom of ritual suicide, for which surely the box will not be used. The purpose of the box is just the opposite, to use a dangerous voltage safely. Always switch it off when not in use. The gradual change to transistors, with their lower voltages, may have lulled us into a position where we have lost our respect for dangerous voltages. ■

Parts List

CB1	3–4-Amp circuit breaker, automatic-reset type
S1	DPDT toggle switch
S2	DPTT toggle switch
S3	DPST or DPDT push-button switch with spring return
R1, R2	47–100k Ohms, ½ Watt
I1, I2	NE-2 neon bulb
Line cord	
3–4' of zip cord	
2 alligator clips with insulating boots	
Metal or plastic (preferred) case 2" × 4" × 6"	

AMATEUR TELEVISION

KPA5 1 WATT 70 CM ATV TRANSMITTER BOARD

- **APPLICATIONS:** Cordless portable TV camera for races & other public service events, remote VCR, etc. Remote control of R/C airplanes or robots. Show home video tapes, computer programs, repeat SSTV to local ATVers. DX depends on antennas and terrain typ. 1 to 40 miles.
- **FULL COLOR VIDEO & SOUND** on one small 3.25x4" board.
- **RUNS ON EXTERNAL 13.8 VDC** at 300 ma supply or battery.
- **TUNED WITH ONE CRYSTAL** on 426.25, 434.0, or 439.25 mHz.
- **2 AUDIO INPUTS** for a low Z dynamic and line level audio input found in most portable color cameras, VCRs, or home computers.
- **APPLICATION NOTES** & schematic supplied for typical external connections, packaging, and system operation.
- **PRICE ONLY $159** delivered via UPS surface in the USA. Technician class amateur license or higher required for purchase and operation.

WHAT IS REQUIRED FOR A COMPLETE OPERATING SYSTEM? A TV set with a TVC-2 or TVC-4 420-450 mHz to channel 3 downconverter, 70 cm antenna, and coax cable to receive. Package up the KPA5, add 12 to 14 vdc, antenna, and any TV camera, VCR, or computer with a composite video output. Simple, eh?

CALL OR WRITE FOR OUR COMPLETE CATALOG & more info on atv downconverters, antennas, cameras, etc., or who is on in your area.

TERMS: Visa, Mastercard, or cash only. UPS COD by telephone or mail. Telephone orders & postal MO usually shipped within 2 days, all other checks must clear before shipment. Transmitting equipment sold only to licensed amateurs verified in 1984 Callbook. Calif. include sales tax.

132 Extra Memories for Your FT-107M

At three cents apiece, why not?

One of the very few operating inconveniences of the FT-107M is the necessity to change the memory switch when changing bands, unless you're lucky and the last 4 digits of the frequency coincide. This is the result of the storage system used by the transceiver. Internally, the memory unit counts the vfo frequency and stores the last four digits into 4 CMOS memories. When you use (recall) a frequency from this memory, a synthesizer contained in the memory unit replaces the vfo and synthesizes the frequency stored.

If you were operating, for example, on 7.1505 MHz, the memory unit stores only the last four digits (1505). Switching bands to 15 meters you get 21.1505 MHz on the display. On 10A you'd get 28.1505 MHz, etc.

Recently, while repairing a friend's FT-107's memory unit, I found that four of the 5101 memory chip's address lines are not used. Of the total of eight lines, only four are used to select the memory channel number; the other four go to +5 volts through 2.2k pull-up resistors. Reasoning that four extra lines give 16 extra possibilities, and needing only 12 (12 bands), there was the solution, ready to use.

The Circuit

The easiest way to code 12 bands (160, 80, 40, 20, 15, 10A, 10B, 10C, 10D, Aux1, Aux2, and JJY, the latter three having been modified for the new 30-, 17-, and 12-meter bands) into four lines is using a diode matrix. I wanted to use as few diodes as possible so I made up Table 1 first.

There's one code that doesn't use a diode, 4 codes that use 1 diode, and 6 codes that use 2 diodes. That totals 11, indicating the necessity to use one code with 3 diodes. Total diodes used in the coder: 19. The diode matrix is shown in Fig. 1.

The bandswitch is connected to a +8-volt supply, and the memories work on a separate +5 volts. A voltage translator was needed to convert the voltages and to isolate any possible timing problem between both supplies. A simple transistor inverter was chosen. No collector resistors are needed, as they are supplied by Yaesu in the form of the 2.2k pull-ups (Fig. 2).

Construction

When doing any work inside the transceiver, switch power off and take the plug out of the wall socket, both for the safety of the operator and the integrated circuits.

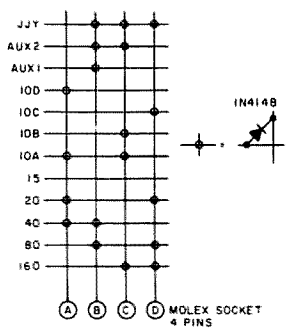

Fig. 1. Diode matrix.

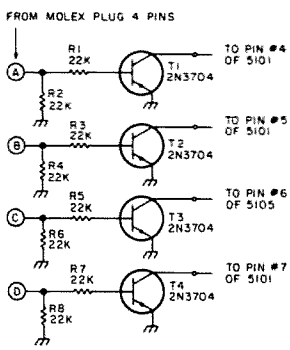

Fig. 2. Inverter/level translator.

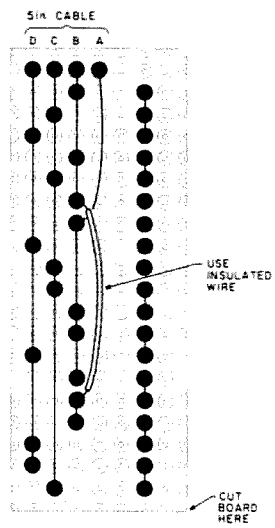

Fig. 3. Diode-matrix wiring pattern, foil side.

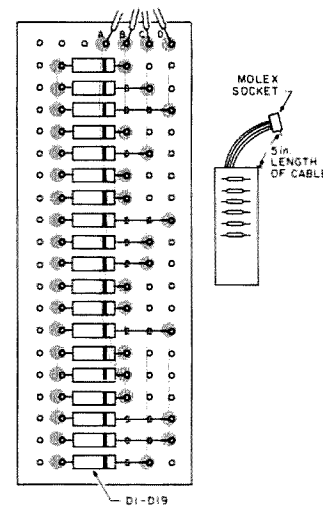

Fig. 4. Diode-matrix construction, component side.

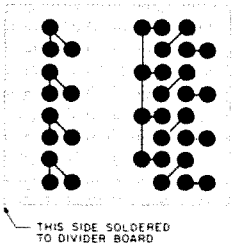

Fig. 5. Inverter/level translator board, foil side.

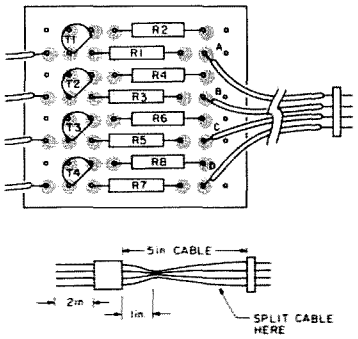

Fig. 6. Inverter/level translator board, component side.

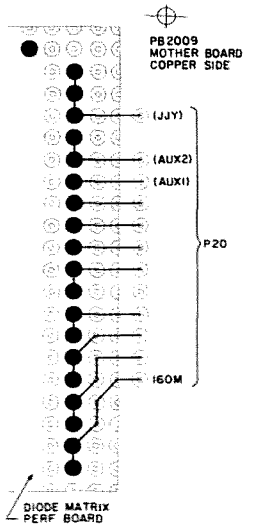

Fig. 7. Diode-matrix board pinout.

Both circuits were constructed on .1" perforated PC board (Veroboard or similar). Mount the diodes as in Fig. 4 to allow easy installation afterwards. Connect the cable to the board before mounting it inside the transceiver. On the inverter board, mount the transistors as close to the board as possible, or the board won't enter into the memory unit. Do connect the cable to the inverter board, but *without* the plug (you will have to pass the cable through one of the holes of the memory unit's enclosure first). Split this cable in two pairs.

Length of the wiring is of no great concern, but the construction as shown in the Figs. is probably the easiest.

Installation

In order to install both boards it will be necessary to remove both the top and bottom covers of the FT-107M (8 screws each). First remove the handle (2 screws).

The diode matrix fits on rf mother board PB-2009 (bottom side of the FT-107M) alongside the solder points of P20. On this plug, all the bandswitch points are available (see Fig. 7). When all the connections between the diode matrix and P20 are made, the construction is rigid enough to stay put without any other mechanical support.

The inverters were installed inside the memory unit. To take out the memory unit (metallic box near the speaker), it's easier to take off the black plastic cover of the rf unit and local unit.

Take off the cover of the unit on the component side. A 2.5 × 25 mm (.1" × 1") border of the protective paint of the divider unit is scraped off with a small knife. (The divider unit, PB-2084, is the small PC board which is upside down near the top of the box.) Then the inverter board is soldered side to side with the divider unit, as shown in Fig. 8. You can take out the divider unit to pass the cable through one of the top holes of the memory unit's box. Then install the divider unit again in the box and affix the plug to the end of the cable. Solder the four separate cables to the 5101 chips, as shown in Fig. 8.

Now close the memory unit again and install it inside the transceiver.

Testing

Connect the two cables together (the one coming from the diode matrix and the one going to the inverters). Don't worry about the polarity. Either way you plug it in, it will work.

Turn on the transceiver, set it on 20 meters, and set the memory switch to channel 1. Try to save and recall a frequency (say 14.1111 MHz). Now switch to 15 meters and store, *in the same memory channel*, another frequency (say 21.2222 MHz). Going back to 20 meters and recalling memory 1, it should still read 14.1111 MHz.

Now try some other com-

GLB ELECTRONICS

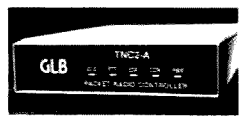
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight.
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement:
9 to 15 Volts DC @ 25 mA typical

Dimensions:
4.6 X 5.90 X 1.0 inches



Total Weight:
12 ozs.

PKIL—Wired and Tested
List— $239.95
Amateur net— $209.95

GLB MODEL TNC-2A KIT

Just when you thought TAPR TNC-2 Kits were a thing of the past, GLB — the first commercial producer of Packet Controllers — Joins the "TAPR Revolution" at last!

binations. No combination should alter the contents of any other band or memory number. If you have any problems, they will probably be wiring errors in the diode matrix. Use Table 2 to debug any wiring error or faulty diode.

Finally

Why so many memories? That is probably what Yaesu thought when they left them out in the first place. Now, an owner of an FT-107M can store the emergency frequency for each band on channel 1. He can scan these frequencies using only the bandswitch (the memory switch remains on channel 1).

Then, on channel 2 he can store his favorite nets for each band. You'll have a lot of unused channels, but at only three cents apiece, too many is better than too few! ■

Inside CoCo's ROMpak

Store your favorite Color Computer programs in ROM—and never type "Load" again.

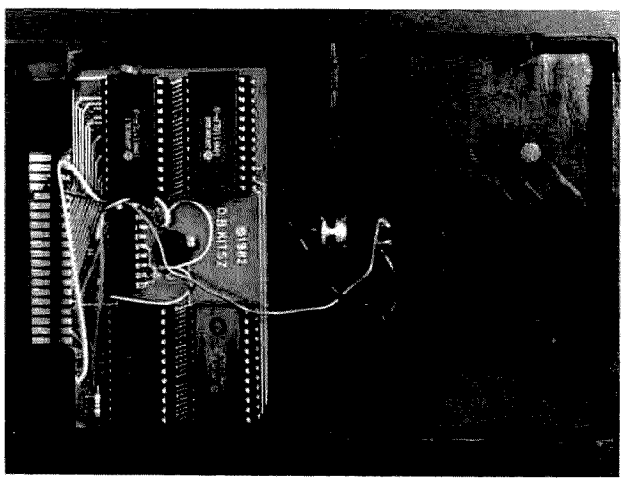

Photo A. A RAM pack configured to give 8K of RAM at the cartridge port. The switch is a "Comprise" auto-execute (see text).

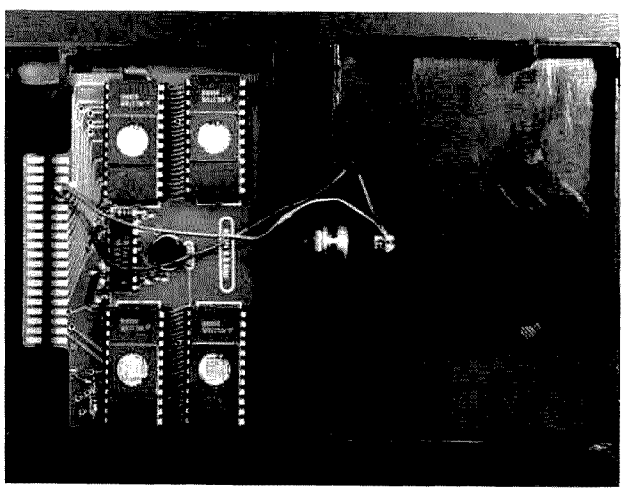

Photo B. A ROM pack configured with 16K of EPROM.

Mailboxes for HF and VHF are becoming more and more popular. As participation increases, there is a growing wealth of information available. In most areas, RTTY pictures, programs, bulletins, and public-domain programs are all available.

There is a tremendous advantage to having the proper software to access these systems. A good program needs

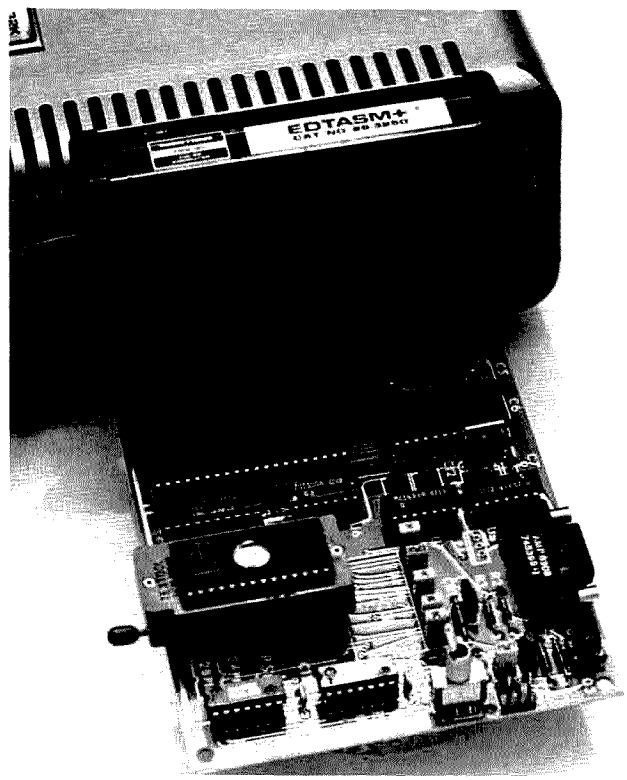

Photo C. The CRA and Associates Universal EPROM Programmer. This unit can be considered a complete development system. It also offers protection to the CoCo via full buffering.

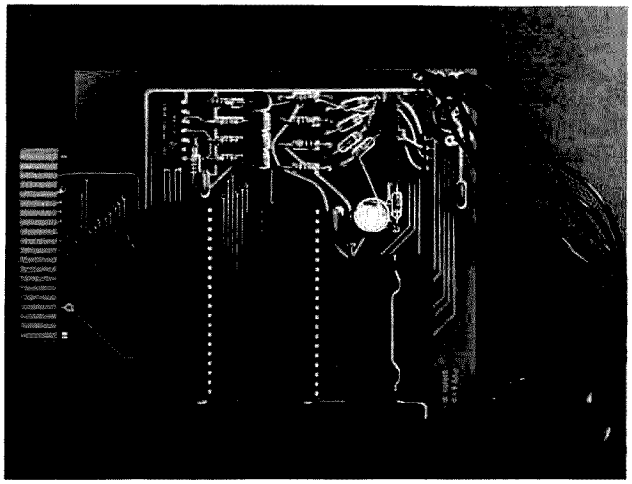

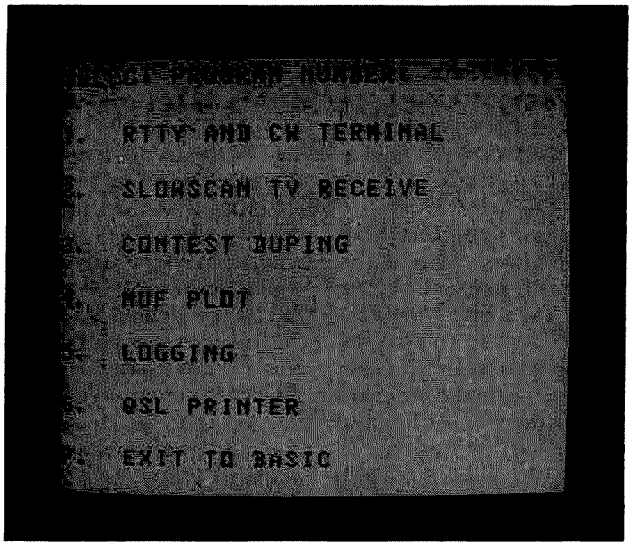

Photo D. The Green Mountain Micro Color Burner—one of the least expensive burners, available in kit form.

A dramatization of what can be programmed. (I wish I possessed a ROMpak with these programs!)

both a transmit and a receive buffer that can be saved and loaded. Using a program which prints only the information you receive can cause you quite a bit of typing should you decide you want to use it again.

The program that I use can be loaded from disk or tape. The program is long—7,341 bytes. A second CoCo is used for my amateur radio operations. I used to hesitate turning that computer off when it was not in use. After each power-down, a long tape load would precede any amateur activity. For this reason, I began searching for a way to keep the program in non-volatile ROM and be able to run it from a ROM pack. Here's how I did it; I call it ROMpak.

The Program

If your program normally runs in memory after a tape or disk load, the chances are that you will not be able to burn it into ROM and run it there. However, you can *store* your program in ROM. If you had a program that would transfer it back to where it should be in RAM and execute it, you would eliminate the tape load.

This is exactly what the loading program does. Once executed, it prints a menu screen with the titles for your programs. You choose the program you want, and the loader puts it into RAM and executes it.

The program as it appears will not do the trick. To make it work you will need to do a little paperwork and figuring. The program itself will require modification.

First, type it as it stands. You will want to assemble it to check for errors. If it is assembled as it sits, EDTASM will give you a wheelbarrow full of BAD MEMORY errors. EDTASM recognizes that you are trying to write to the ROMpak and will tell you that is a no-no. Change line 190 to read:

```
190  ORG  $1000
```

Now try an assembly with the following switches: A/IM/WE/AO. If everything checks, change line 190 back to the original and save the source code.

Your Programs

Although Basic programs can be loaded and run in this manner, this program will work only with machine-language programs. You will need a number of addresses from each of these programs:

1. Where the program begins in RAM.
2. Where it ends.
3. Its length.
4. Where it executes.
5. Where to load it into the ROMpak.

From Basic, CLOADM one of the programs. Do not execute it, but return to Basic. The starting address of this program can be found by typing:

```
PRINT PEEK (&H1E7)
```

and

```
PRINT PEEK (&H1E8)
```

The first value is the most significant byte. Each of these will have to be changed to hex using EDTASM's Z-Bug calculator and concatenated. The ending address is given by:

```
PRINT PEEK (&H7E)
```

and

```
PRINT PEEK (&H7F)
```

The execution address is given by:

```
PRINT PEEK (&H9D)
```

and

```
PRINT PEEK (&H9E)
```

In Z-Bug, calculate the program's length. Enter this information in the worksheet (Fig. 1). Do this for all of the programs you wish to load into the ROMpak.

Modifying the Loader

The loading program requires a number of modifications before we can determine its length. Load the source code and print the menu lines. Modify these with the names you wish to use with each program. You may have more than seven programs to load, in which

ROMpak Formatting Worksheet

	LD#TO		LENGTH#	EXEC#	STPG#	
Loader						
Program #1						
Program #2						

Fig. 1. ROMpak formatting worksheet.

case you will have to expand the menu. If you have fewer than seven and you wish to load more into the ROMs at a later date, the area of ROM where the future menu lines will reside will have to be left blank.

The lines reading FDB $0D0D simply space the menu lines apart on the screen. The program looks for a "$FF" value to end the menu screen. This can either be put in (as in the program) or assumed as unburned ROM.

Once the menu has been modified, type A/AO. As the assembler scrolls the screen, it can be made to pause by pushing both the <shift> and <@> keys. The last byte of the menu, the "$FF" character, is the last byte of the program. By pausing the scrolling when this part of the program is on the screen, the ending address of the loader can be determined. Knowing that the start is at $C000, you now can complete the worksheet. You can also determine this ending address by assembling the source code to the printer (A/LP).

Once the worksheet is complete, enter the values into the source code that the program will need. If you are planning on expansion, remember that you will probably have to make two burn passes. The first will start at $C000 ($0000 relative to the start of the ROM). The second pass will leave the future menu lines unburnt and start loading in the stored program code for the first program.

Building the ROMpak's Code

There are three methods of building the code that will go into the ROMpak. The first is to use the computer's RAM, pretending that some arbitrary byte is actually $C000. Then, using the Z-Bug "P" command, make a copy of the memory.

Since the loader is not memory-independent, you will not be certain that the program will work at its proper address until you have the ROMs burnt. Then it's too late. Double and triple check any code put together this way.

A much more desirable

Program listing.

method is to use a RAM pack. This is a ROM pack configured with RAM. Photo A shows a Green Mountain Micro RAM pack configured for the 6116 chip. This gives 8K of memory at the port. 16K can be addressed there and this same RAM pack can be modified to accept four 6116s (piggyback) to have 16K available. (Write to Green Mountain Micro at Bathory Road, Roxbury VT 05669.

If a RAM pack is used, a simple modification to the computer will have to be made. A stock computer cannot write to addresses $C000 to $EFFF. Different RAM packs give different instructions to do the modification. The most simple method to allow the RAM pack's use is to ground pin five of the 74138 multiplexer (U10) through a switch. I have seen other methods that cut pins and use other "no-turning-back mods." Some of these will affect memory map number one in such a way that it cannot be used. That will make full RAM programs, like the VIP Library, useless. Don't cut pins.

The third method entails copying addresses $8000 to $FEFE into the unused 32K of RAM in the 64K chips. This was done by Ray Guavreau in the January, 1984, issue of *Rainbow* magazine (PO Box 209, Prospect KY 40059). You then switch to all RAM and can use the computer's upper RAM to simulate a ROM pack.

My code was assembled in a RAM pack, and this is the way it was done. EDTASM is position-independent and can run anywhere in memory above about $1000. Copy it to RAM by using a U C000 1000 27FF command. It then can be saved to tape with P 1000 27FF 1000. The RAM pack can now be used with EDTASM.

Make an object code tape of your loader. Load this from Z-Bug into the RAM pack. As each of your programs is moved into the loader, you will have to ensure that they do not cream EDTASM. For example, if EDTASM is running at $1000 and you try to load a program in at $1E01, you will load over EDTASM and crash the system. It may be necessary to move EDTASM all over the computer as you proceed.

Load your program into memory using Z-Bug. Move them into the RAM pack with the "U" command. After they are are all loaded, make a tape print of the RAM pack with P RAMPAK C000 (hex address of last byte of last program) C000.

The acid test is to now power down and bring the system back up, reloading the RAM pack. Check each program thoroughly to see that everything is working. If you do find a program which crashes, go back to the worksheet and recalculate all values. Hex numbers are tricky.

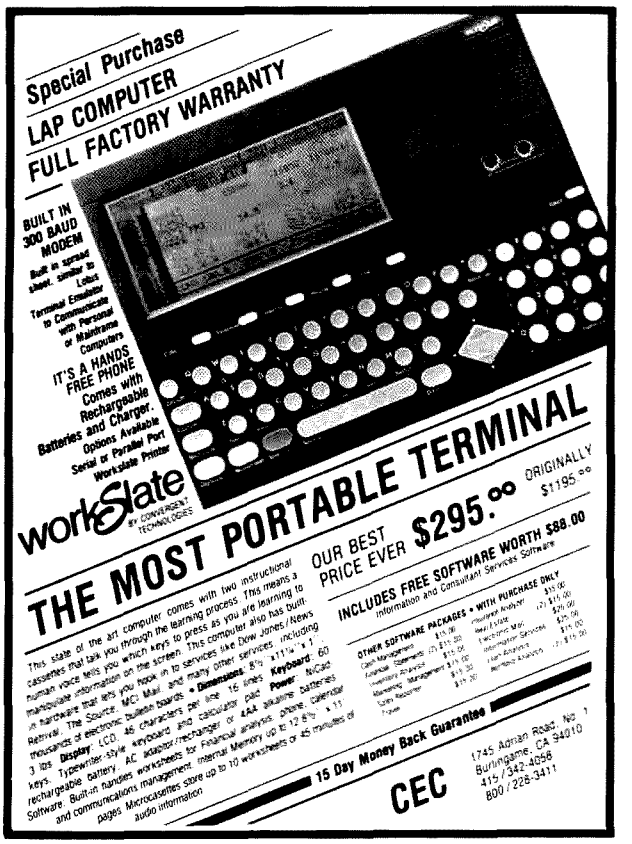
ROM Packs

Photo B shows a Green Mountain Micro ROM pack configured with 16K of 2732 EPROM. I have two programs burnt which occupy about 9K. This leaves about 6K for future expansion. (Come on people! Let's see some packet software for the 6809 Color Computer!)

Autostart on a typical ROM pack is achieved by shorting pin seven to pin eight on the connector. The pin assignments go top-bottom-top-bottom so these two pins are above and below one another on the ROM pack. If this is done each time the computer is powered up, it will execute $C000 automatically. Rather than allow it to do that, I have installed a push-button between these two pins. By tapping the button, it effectively does an EXEC &HC000 command. I still can get back into Basic for my day-to-day needs without a power-down and removal of the ROMpak.

PROM Burners

PROM burners used to be $500.00 devices that required an excellent fluency in hex numbers. That has changed.



One of the cheapest available burners is available from Green Mountain Micro; it can be purchased in kit form, and except for four transistors is easy to build. These four transistors have extremely close lead spacing and require the utmost care in soldering. The software that can be purchased will allow you to program at least six types of EPROM including a 68764. This last EPROM can be put into one of the sockets used for Basic or Extended Basic.

For a development system, CRA & Associates (31235 Avon Road, Westlake OH 44145) offers a "Universal EPROM Programmer" for the CoCo. A number of bells and whistles are built into this board. First and foremost, a program pack connector is built onto the board. This allows the EDTASM to remain on the board and available. A (true) RS-232 port capable of up to 19.2 KB is also standard. This could be used to burn ROMs for use in other non-6809 systems. Everything on the board is socketed. Protection is obtained through full buffering and current limiting on the program pulse. What else could you ask for?

I cannot detail how the code is burnt into the ROM since each burner is different. All have software available. They show how to take your object tape and put it into ROM.

Conclusion

When I have a few free minutes, I like to pop down to the shack and get into a QSO. The ROMpak has relieved me of the hassle of a tape load to bring up my terminal. Also, I am no longer hesitant to power down after each operation. It is a nice system that could easily be implemented by software designers to put their programs into a ROM pack. ■

Build A Digital IC Trainer

A great helper for testing components, as well as experimentation and circuit development.

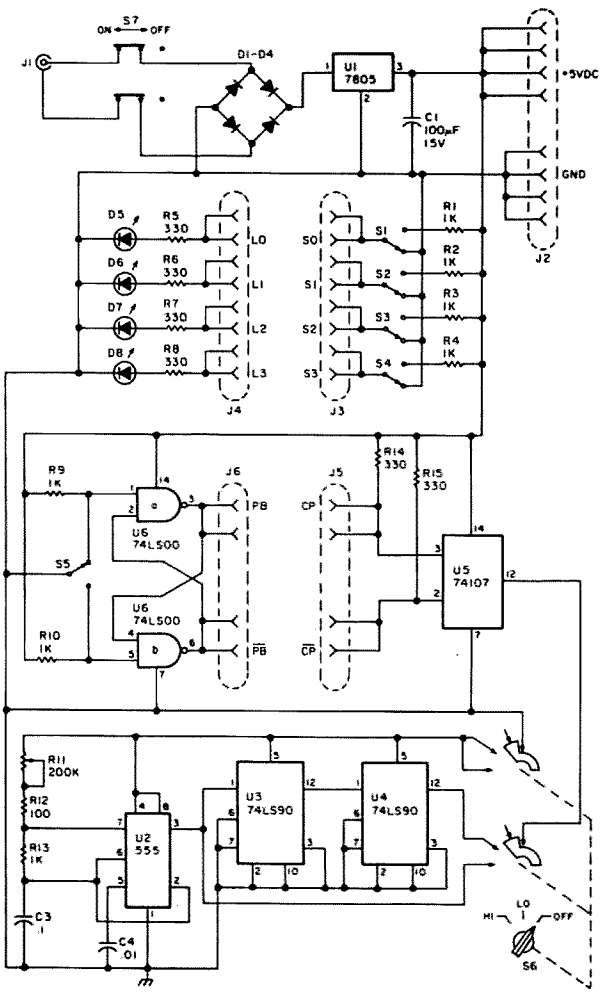
Have you made the transition to integrated circuits yet? Perhaps, as in my case, you find that integrated circuits aren't quite as convenient for the experimenter as has been rumored. Let me explain that bit of heresy.

With discrete components, you can throw together a simple circuit quickly by tacking the component leads together as required; with an integrated circuit, the leads are so close together that such an approach invites short circuits and component destruction. The answer to that problem is a trainer designed for digital integrated-circuit experiments.

As I considered the requirements for an IC trainer for myself, I came up with the following as features that should be provided:

- Sockets to accommodate standard ICs with from 8 to 40 pins
- Switches for use in setting up inputs to the experimental circuits
- LED indicators
- Internal pulse generator to provide pulse train for input to experimental circuits
- Internal power supply
- Interconnections in setting up experimental circuits made by jumpers and requiring no soldering

The most convenient socketing arrangement I could find to suit my requirements was a modular



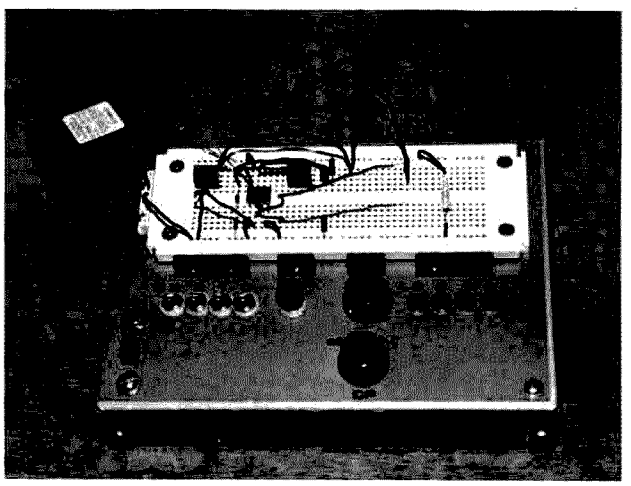


Fig. 1. Digital IC trainer schematic.

The digital IC trainer.

IC breadboard socket such as marketed by Radio Shack. This socket has 550 holes with the same spacing as the pins on common ICs. There are 47 columns of 5 holes which are connected internally in both the upper half and the lower half of the socket. Any of the standard integrated circuits can thus be inserted in the socket astride the center divider and each of its pins will be connected to a column of connection points. Across the top and bottom of the socket are rows of holes connected together horizontally to serve as power-bus connections. Connections can be made to the socket by 22- to 30-gauge solid-wire jumpers.

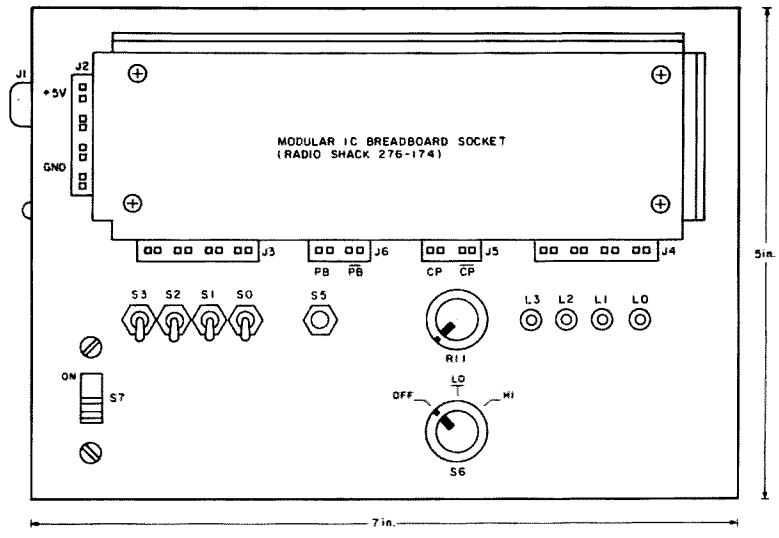

Fig. 2. Panel layout.

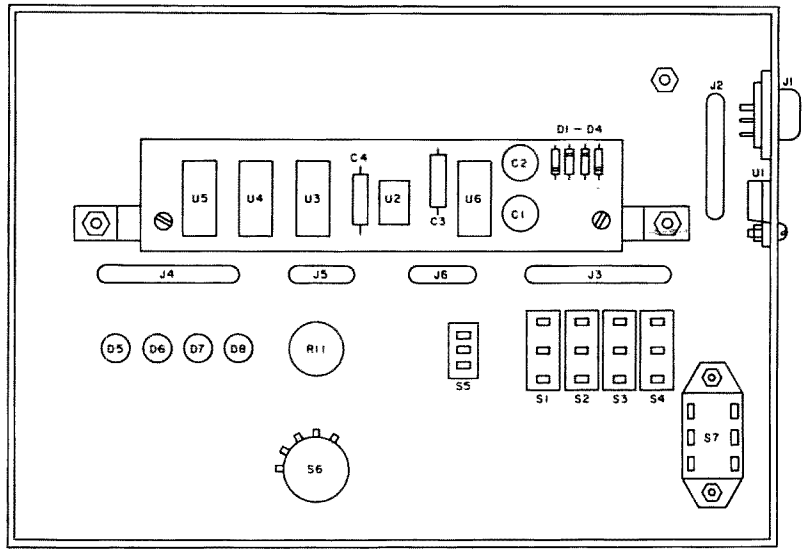

Fig. 3. Interior view showing major components.

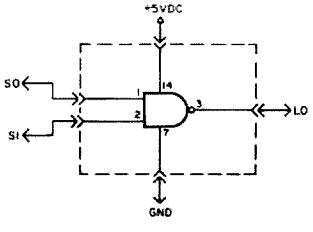
Circuit Description

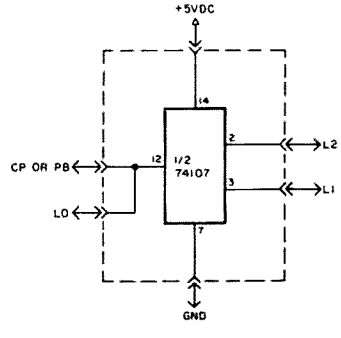


The circuit used is shown in Fig. 1. A power section is provided as well as a switch section, an indicator section, and a pulse-generator section.

The power section has no transformer since there wasn't enough room in the chassis I selected. Instead, the input is connected to a full-wave bridge whose output is regulated by U1 to +5 V dc. The power source connected to J1 can be any voltage from 7 to 35 volts, the limits of the regulator. If the input is ac, the diode bridge serves as a rectifier. If the input is dc, the diode bridge serves as an automatic switch to connect the proper polarity, so it doesn't matter what polarity is connected to J1.

Four SPDT toggle switches, S1–S4, are provided to select between +5 V dc and ground to provide either logic 1 or logic 0 at the jacks labeled S0 to S3. Limiting resistors R1 to R4 prevent catastrophic failures provoked by connecting +5 V dc with 1 Ampere capability to the test sockets. A push-button switch, debounced by the NAND gate circuit, provides a push-button output and its complement at the jacks labeled PB and $\overline{PB}$.

Four red light-emitting diodes are used as logic-level indicators accessible by connection to jacks labeled L0 to L3. Limiting resistors R5 to R8 are insurance against LED failure and are selected to limit current through these indicators to the specified value even when the full dc voltage available is connected to them.



The pulse generator is a

Fig. 5. 74107 flip-flop test.

bit more involved. U5, a 74107 flip-flop, is used primarily to provide a clock-pulse output and its complement at jacks CP and $\overline{CP}$. This flip-flop also divides by two, so this must be considered when selecting the frequency of its driving source. Switch S6 selects, as the input for U5, either the output of multivibrator U2 (high range), the output of a divide-by-100 chain (low range), or ground (off). The multivibrator is designed to operate over the range of 500 Hz to 50 kHz, adjustable by R11, so the CP output is 2.5 Hz to 250 Hz in low range and 250 Hz to 25 kHz in high range.

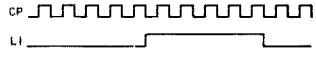

Fig. 6. 7490 test.

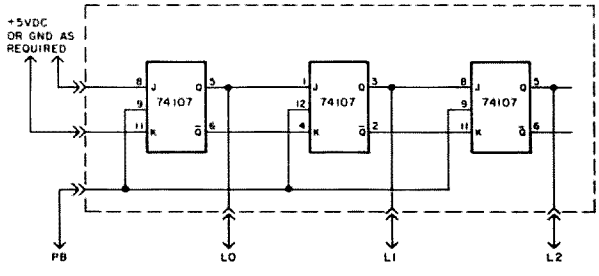

Fig. 7. Shift register development.

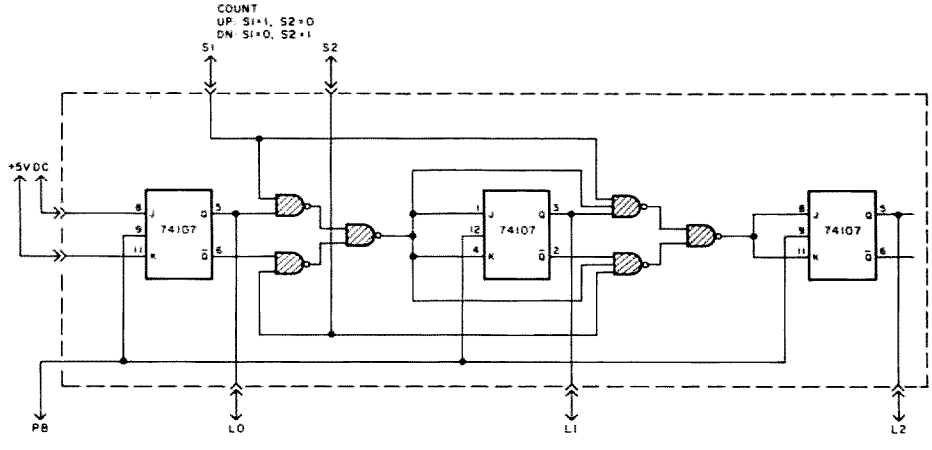

Fig. 8. Parallel up/down counter development.

Construction

The breadboard socket is mounted on the top of a 5″ × 7″ aluminum chassis which occupies about half the available panel space. The remainder of the panel space is devoted to the controls, indicators, and sockets as shown in Fig. 2. The sockets that serve as terminations for the switches, indicators, and power sections are made from IC sockets so that they will be similar to the breadboard socket. Switches and indicators are numbered S0–S3 and L0–L3, respectively, on the panel, conforming to the numbering of lines in a digital bus.

The interior of the digital IC trainer is shown in Fig. 3. The +5-V-dc regulator is attached to the chassis, insulated by mica for heat sinking. As you can see, there is plenty of room for future additions and expansions.

Using the Trainer

The digital IC trainer simplifies testing and experimenting with digital ICs. The IC is inserted into the socket and is powered by appropriate connections to the power buses, which are jumpered to the +5-V-dc and ground connections. Components and jumpers are plugged into the sockets as needed to set up the circuit.

As a simple example, look at the test circuit of the 7400 NAND gate shown in Fig. 4. Pin 14 is jumpered to the +5-V-dc bus, and pin 7 to the ground bus. The inputs, pins 1 and 2, are jumpered to switches S0 and S1 and the output, pin 3, is connected to indicator L0. With power applied, switches S0 and S1 are manipulated to set up the 4 possible input combinations. L0 is read as 1 if on and 0 if off, and the results are compared to the NAND-gate truth table.

A flip-flop can be tested as shown in Fig. 5 by wiring it according to its schematic and clocking its input with PB, using one of the indicators to monitor its output for proper toggle action.

A counter, such as the 7490, can be tested as shown in Fig. 6. Its input can be clocked using CP at a low frequency—or PB can be used so that the division ratio can be determined.

Though useful for testing ICs, the digital IC trainer has been most valuable to me in experimentation and circuit development. For example, I was asked to design a three-flip-flop shift register capable of serial data entry, complement operation, up-count, and down-count. While some, no doubt, find it possible to design entirely on paper and then to build a working circuit, I much prefer to take a project such as this in smaller steps. The digital IC trainer is ideally suited for developing a circuit in steps and provides a means for testing each step before proceeding.

A serial shift register is made by connecting J-K flip-flops so that the inputs to the first flip-flop can be manipulated to clock in a 1 or a 0 and the state to which each succeeding flip-flop will clock is determined by the state of the previous flip-flop. Such a shift register is shown in Fig. 7. The jumpers shown indicate connections from appropriate holes in the breadboard socket to the trainer sockets indicated. Power connections are not shown but are made in the same manner, using jumpers. To enter a 1, the push-button is used to clock the circuit with the J input connected to +5 V dc and the K input connected to ground. For a 0, these connections are reversed. (The operation of the shift register is verified using the trainer before proceeding to the next step.)

The shift register can be modified to form a parallel up/down counter if the first flip-flop is wired to toggle each time it is clocked and the following flip-flops are made to toggle dependent on the Q or $\overline{Q}$ outputs of the preceding flip-flops. If the Q outputs are used, the count will be in ascending binary

sequence. If the Q outputs are used, the count will be in descending binary sequence.

This modification consists of wiring the J and K inputs of the first flip-flop to +5 V dc and installing the six gates shown shaded in Fig. 8. When S1 is at logic 1 and S2 at 0, the upper gates are enabled and the Q outputs are selected for up-count. When S1 is at 0 and S2 at 1, the lower gates are enabled and the $\overline{Q}$ outputs are selected for down-count. As in the case of the shift register, the operation of this circuit is verified before proceeding.

The main difference between the shift register and the counter is the source of the J and K inputs of each flip-flop. These two circuits can be combined if provision is made for selecting the proper signals as the J and K inputs for each operation. Similarly, the complement operation can easily be included at this step as it requires only that both inputs of all flip-flops be held high while the circuit is clocked. This switching can be accomplished by the addition of the 12 gates shown shaded in Fig. 9. As before, S1 and S2 control the count sequence. S0 selects shift register operation with a logic 1 or counter with a 0. A 0 on S3 overrides all other functions, forcing all flip-flop inputs high for the complement operation.

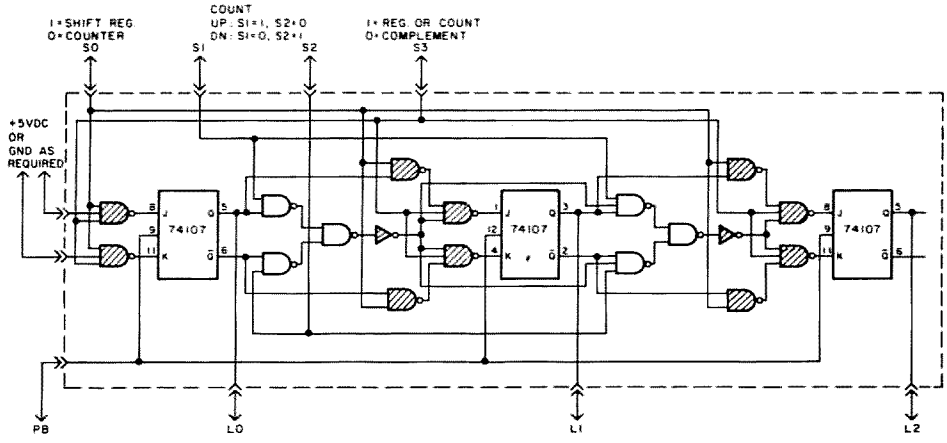

Fig. 9. Shift register and counter combined.

Though the circuit illustrated here has limited practical application, it serves to illustrate that the digital IC trainer is a convenient aid in the development of complex circuits. As the breadboard socket becomes crowded by the inclusion of more circuits, the space available can be extended simply by attaching another socket. These sockets provide for such expansion by means of interlocking grooves. The only limitation is the capacity of the power supply...and the size to which you want to build the working area.

I have found the digital IC trainer to be a valuable addition to my shop. It has proven to be a great help in testing components as well as in experimentation and circuit development. Why not build one for yourself and see if it doesn't make your digital experimentation less painful?■

"When You Buy, Say 73"

Get Organized Today With Argo's Helper

If your present QRP station is comprised of a half-dozen black boxes interconnected with several cables, then this may be the construction project for you.

F. T. Marcellino W3BYM
13806 Parkland Drive
Rockville MD 20853

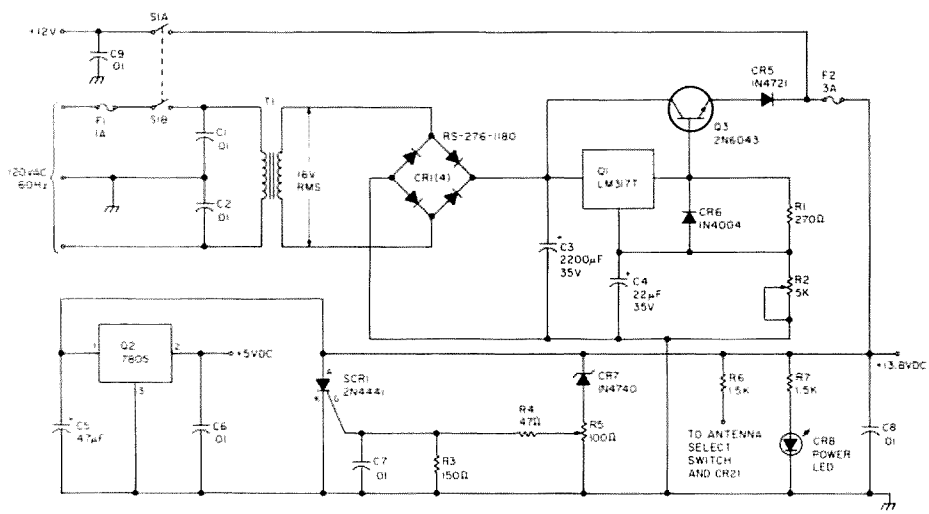

Fig. 1. Power supply and crowbar protection circuit.

Attention QRPers! How would you like an organized station? Would you prefer your favorite accessories packaged in one cabinet? Would you consider increasing the talk power of your SSB signal and having additional features for more operating enjoyment? If you answered yes to just one of these questions, you will

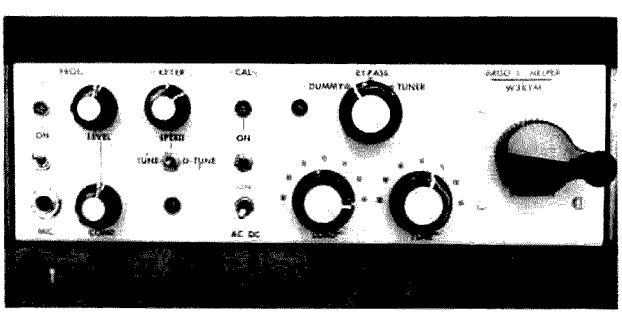

Photo A. Front-panel view—notice arrows indicating direction for tune and delay tune. LED colors are red for power and CAL, green for dummy load and processor.

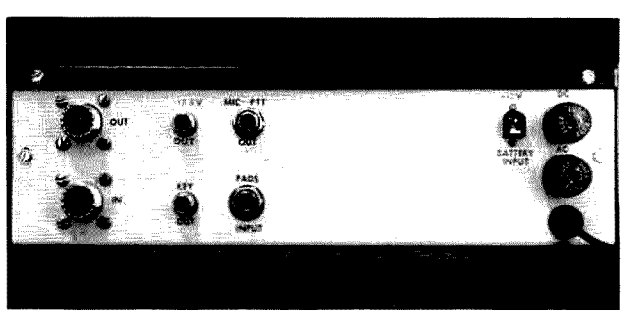

Photo B. Rear-panel view—rf connectors are SO-239, plus 13.8 and key-out are RCA phono types. Plus 12-V-dc battery input is a panel-mount coaxial power connector.

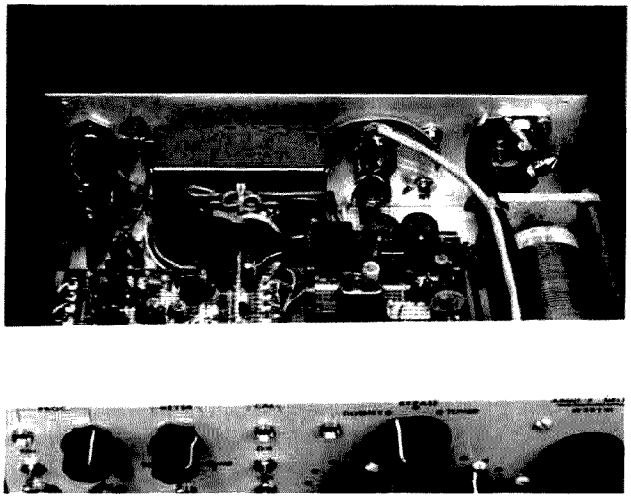

Photo C. Internal rear portion showing major power-supply components. Notice bypass capacitors and RFC1 choke placement.

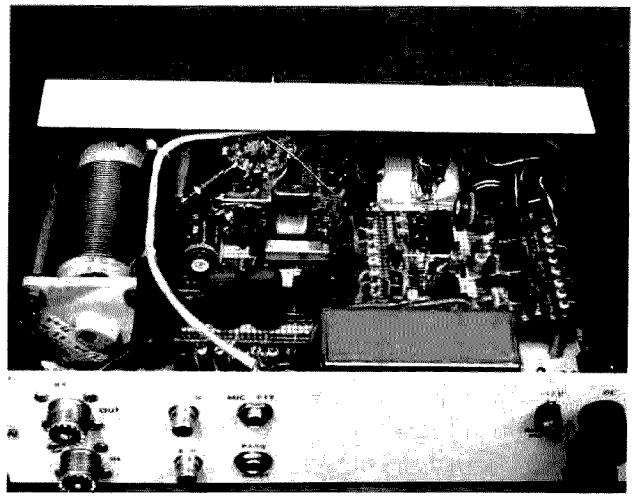

Photo D. Internal front portion showing board layouts and rotary inductor. Notice the RG-58/U routing.

find this article interesting reading. If you answered yes to more than one question, you should consider building a similar project.

This article describes a QRP station accessory that I built to complement my Argonaut 515 transceiver. For those who keep abreast of construction articles in this magazine, you might remember my first station organizer, the "Supernova," that was published in August, 1981.

Since that time I've enjoyed QRP operation a great deal and decided to expand my capability to include SSB operation. I traded my HW-8 for the Argonaut 515 and at that time began the design of the second organizer, which I named "Argo's Helper." Some of the original ideas and circuits are included, but Argo's Helper has several new ideas to provide increased pleasure.

This project features a 100-kHz crystal calibrator, a switchable dummy load with LED indicator, a speech processor with adjustable gain and compression, a delay-tune and full-tune function, an ac power supply with over-voltage crowbar protection and provision for operation from a dc power source, and finally, an antenna tuner using a continuously-variable rotary inductor.

The entire station organizer is neatly packaged into a Ten-Tec cabinet (model LW-10) measuring 10½" × 7" × 3¼". The front-panel switches, knobs, and LED assemblies were purchased from Radio Shack, except for the offset knob for the inductor, which I picked up at a flea market. A turns-counting dial was purposely omitted because of limited front-panel space and the need for only a few turns for most coupling situations.

The internal construction is shown in the photos. For ease of construction, two PC boards (RS 276-162) were used, incorporating point-to-point wire and solder construction. The power supply and crystal-oscillator circuitry are mounted on the center board, while the speech processor and keyer circuits occupy the remaining board.

The series-regulator output transistor is mounted near the back and below the power-supply board, directly on the chassis. The chassis provides an excellent heat sink when the transistor is mounted using a mica washer and thermal grease. The dc output from the regulator is controlled by a board-mounted trimpot, R1, which I preset to 13.8 V dc. The over-voltage crowbar circuit mounted on the power-supply board is preset to about 15.5 V dc using another board-mounted trimpot, R5.

Construction of the tuner isn't critical but requires special attention for mounting the variable capacitors, C38 and C39. These two capacitors must be isolated electrically from the front panel on both their rotors and stators. I accomplished this by using nylon screws with fiber washers threaded into the pre-tapped holes in the capacitor frames. Clearance between the capacitor frames and the bottom surface of the chassis was extremely tight in this installation, requiring a small piece of plastic sheet for complete isolation.

Most of the tuner wiring is on the switch wafer and the two capacitors. The rotary switch is another flea-market purchase which I chose

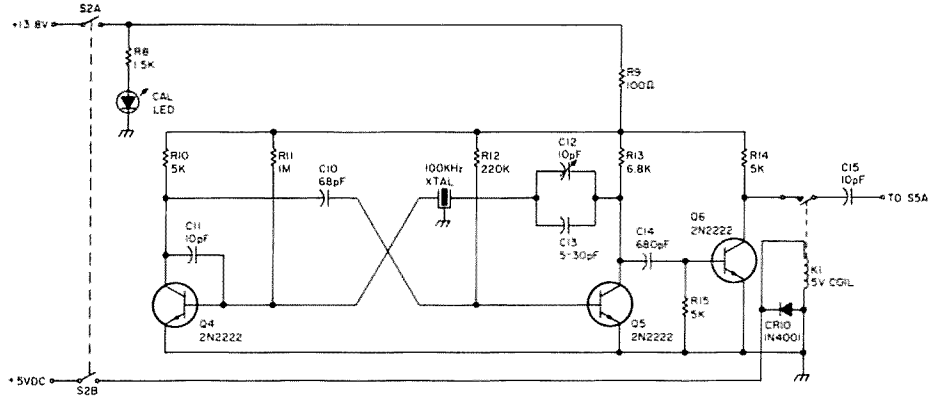

Fig. 2. Crystal calibrator circuit.

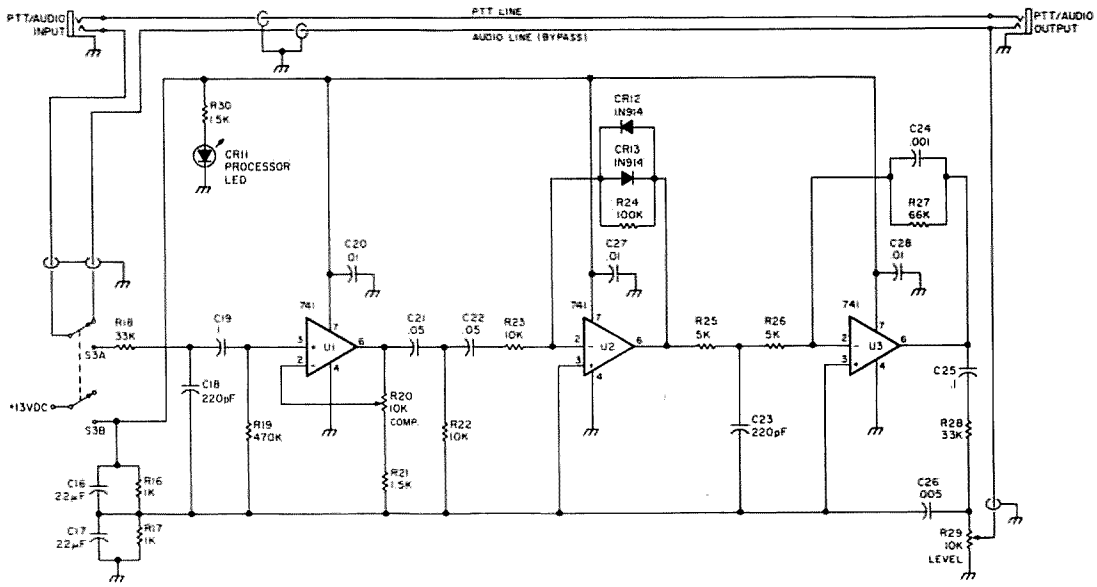

Fig. 3. Speech processor and bypass circuit.

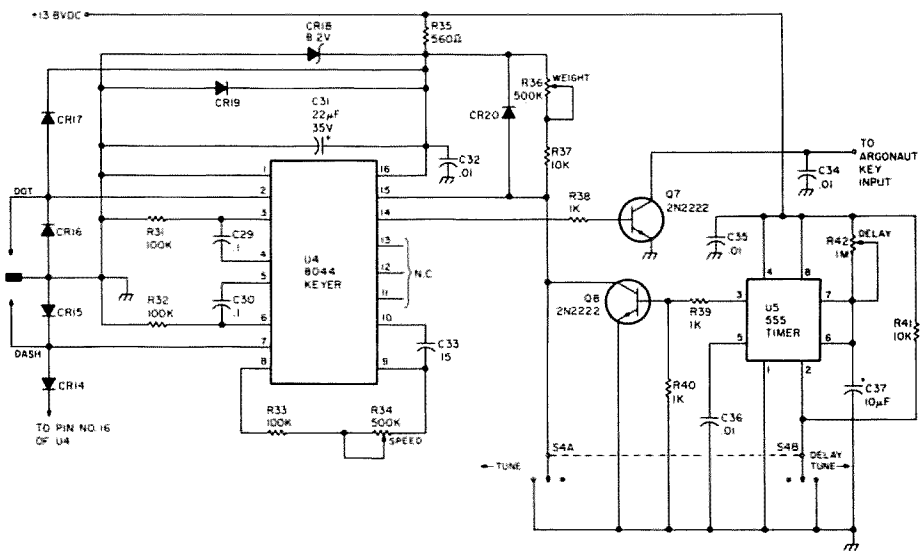

Fig. 4. Keyer and delay-tune circuit.

because it is a miniature, low-loss ceramic type. RG-58/U coax cable was used with the braid grounded from the SO-239 connectors to both wiper arms of switches S5A and B. One bus wire (AWG 14) was used to connect the top of inductor L1 to both capacitors C38 and C39.

The RFC1 choke is mounted directly across the rf-output SO-239 connector. The purpose of this choke would normally be to prevent high voltage from reaching the antenna in the event of a capacitor failure in the final amplifier. In my application, I am using the choke as a dc return path for the dummy-load indicator, LED CR21. When front-panel switch S5A connects the 50-Ohm dummy load to the transceiver, S5B will return the cathode of CR21 to ground via RFC1.

The power-supply circuit is very conventional (Fig. 1). The power transformer has no brand name, but is rated for 16 V rms at 4 Amps. This unit was purchased for $4.00 at a local hamfest, but other transformers (e.g., 18 V rms at 2 Amps secondary) will do equally as well. Power switches S1A and B control either ac or dc input power and diode CR5 protects the regulator circuits when using a dc power source.

The over-voltage-protection circuit will prevent the 13.8-V-dc line from rising above 15.5 V dc if the LM317T regulator fails. If a failure occurs, the gate voltage of SCR1 will reach the trip point set by trimpot R5. This action forces SCR1 into conduction and switches the 13.8-V-dc line to near ground potential very quickly while simultaneously exceeding the limits of fuse F2. F2 will open circuit, thereby protecting the Argonaut and its "Helper" from harmful voltages.

The front-panel power LED and dummy-load LED have their current-limiting resistors, R6 and R7, mounted on the power-supply board. Notice the abundant use of .01-uF disc bypass capacitors. These are very cost-effective devices used throughout the station organizer to bypass any unwanted rf currents to ground.

Fig. 2 shows the 100-kHz crystal calibrator. This circuit uses a standard multivibrator circuit built with discrete parts. Care should be taken to follow the circuit very closely. The 10-pF capacitor, C11, is necessary to guarantee oscillator starting each time the power is applied via S2A and B. The two capacitors, C12 and C13, can be replaced with one larger variable capacitor if one is available. In my circuit, I soldered the case of the crystal to ground using a

short piece of bus wire for added stability. The calibrator will provide an S7 to S9 signal from 100 kHz to 30 MHz, and to ensure this high output, capacitor C14 must be connected to the collector of Q5. The circuit will work if C14 is connected to Q4's collector, but the output is greatly attenuated at high frequencies. Relay K1 was included to protect the output buffer transistor Q6 from rf overload when the Argonaut is transmitting.

Fig. 3 shows the speech processor. This circuit uses a single supply with on-board filtered voltage division. The following brief description tells how the circuit works. The first stage is a common audio amplifier with its gain controlled by potentiometer R20. The second op amp is a audio amplifier with diodes in the feedback loop. If U1's output remains below ±0.6 V dc, it will behave like an amplifier. When audio peaks exceed 0.6 V dc, CR12 and CR13 will conduct and limit the gain of U2. This action keeps the audio level constant on U2's output. U3 is a bandpass filter that removes unwanted harmonics and R29 controls output level.

I built my processor using three 741 op amps in 8-pin packages. The reason for the three-chip design instead of one quad is the ease of component layout. You can use the single quad, but placement of the many components around it presents quite a challenge.

Fig. 4 shows the conventional Curtis Keyer circuit which I used in the first organizer, and because of its trouble-free operation, I decided to use it in this project. The output keying circuit is slightly different, consisting of R38, C34, and Q7. The Argonaut key input presents about a 2-V-dc positive signal to ground. This signal, and hence the keying function, is easily controlled by driving the NPN transistor from the 8044 output pin.

I've added a new feature for holding the key line down for a preset interval; I call it "delay tune." This has been very useful during tune-up periods, allowing both hands to be free to adjust the tuner's inductor and capacitors. Using trimpot R42, I've set the delay tune for 6 seconds, which seems to be a good time interval for this function. The 1-M trimpot will allow about a 10-second maximum delay. Switch S4B (spring-loaded side) will initiate the timing cycle of U5. I also included the conventional full-tune function, which holds the key line down all the time with S4A (standard toggle side). This switch, a DPDT, spring-loaded, one side only, is another special item not readily available, which I found at a flea market for $2.00.

Fig. 5 shows the antenna tuner with switchable dummy load and indicator. The load was fabricated using two 100-Ohm, 2-Watt carbon resistors connected in parallel. The tuner circuit is a basic T-match circuit and allows me to use practically any antenna. I've included a tuner bypass feature which effectively removes the tuner when a resonate antenna is available for the operating frequency. The two variable capacitors, C38 and C39, are single gang types, having about 400 pF each. Note the connections from the crystal-calibrator output and from the 1.5k-Ohm R6 for the indicator LED.

Calibration and setup of the various trimpots and capacitors is not difficult, but requires a little patience. Adjustment of the main dc voltage is done by monitoring the voltage between the cathode of isolation diode CR5 and chassis ground. Trimpot R2 will set this voltage to any desired value between 12 and 15 V dc. I set my power supply to 13.8 V dc to be in compliance with Ten-Tec's specifications.

The over-voltage crowbar circuit will clamp the main dc voltage to ground in the event of an LM317T failure. Fuse F2 should be temporarily replaced with a 100-Ohm, 2-Watt resistor for this adjustment. Starting with the arm of R5 adjusted to the ground side, slowly rotate the trimpot until the main dc voltage drops to zero. When the trip point is located, rotate the trimpot back toward the ground side about two turns to reach a trip level of 15.5 V dc. In my

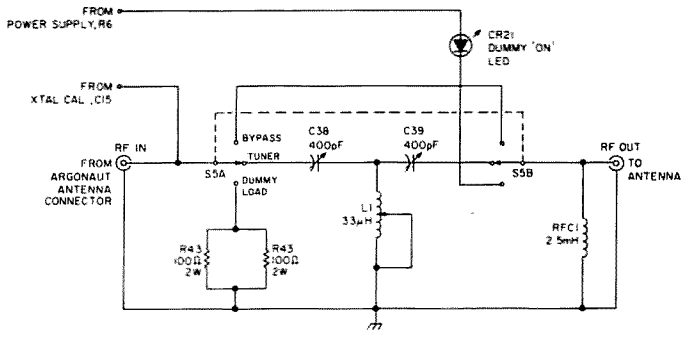

Fig. 5. Antenna tuner, bypass, and dummy-load circuit.

installation, a 10-turn trimpot offered increased settability.

The crystal calibrator was calibrated using my R-1000 receiver, but a frequency counter would be a better standard if available. Set the receiver to a multiple of 100 kHz near 30 MHz and couple the output of C15 directly to the receiver's input. At this frequency and with the same component values, capacitor C13 will vary the output a total of 6 kHz. Zero-beating WWV at 10 MHz is another good method using a suitable receiver. Obviously, the higher the test frequency used, the greater the accuracy of the calibration.

The keying-circuit adjustments are mostly self explanatory. Speed control R34 can be set easily for any wpm between 8 and 50. I set R36, the weight control, for 50/50 operation with a midscale setting. Other weight settings can be determined by monitoring the transmitted signal with an independent receiver.

Operation of Argo's Helper combined with the Argonaut 515, whether in my shack or using a dc power source in the wilderness, has been very enjoyable. The unit is more versatile than the first organizer and could be modified for operation with other QRP rigs. The delay-tune function is used almost exclusively and really helps by freeing my other hand for tuner adjustments. The speech processor gives the 5-Watt signal additional punch and makes a good conversation topic when switched in and out without informing the other operator. The tuner allows better matching on all bands while using a wider variety of antennas.

I hope some of you QRPers will find my ideas useful, or better yet, are motivated to construct a similar unit. If your present QRP station is comprised of a half-dozen black boxes interconnected wth several cables, then this may be the project for you. I will be glad to answer any questions if additional clarification is needed or a circuit problem is encountered. ■

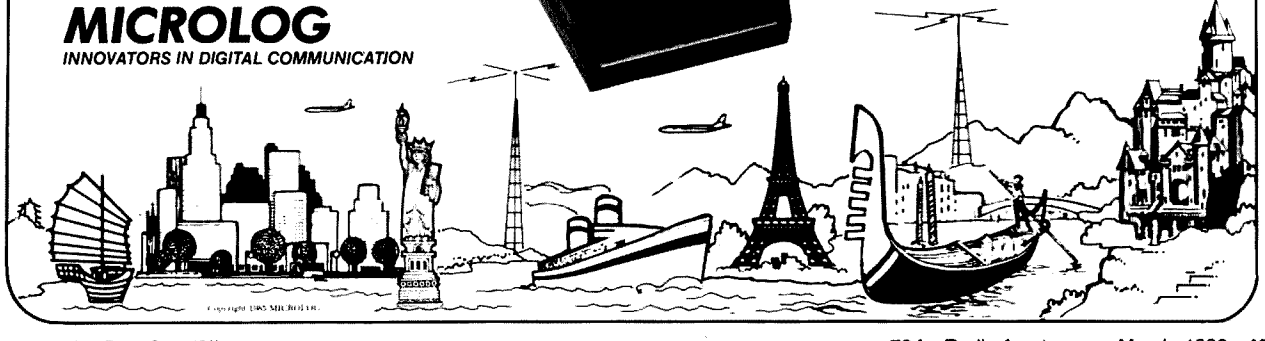
Copy Worldwide Short-wave Radio Signals on Your Computer

Remember the fun of tuning in all those foreign broadcast stations on the short-wave radio? Remember those mysterious sounding coded tone signals that baffled you? Well, most of those beeps & squeals are really digital data transmissions using radioteletype or Morse code. The signals are coming in from weather stations, news services, ships & ham radio operators all over the world. Our short-wave listener cartridge, the "SWL", will bring that data from your radio right to the video screen. You'll see the actual text as it's being sent from those far away transmitters.



The "SWL" contains the program in ROM as well as radio interface circuit to copy Morse code and all speeds/shifts of radioteletype. It comes with a cable to connect to your radio's speaker/earphone jack, demo cassette, and an excellent manual that contains a wealth of information on how to get the most out of short-wave digital DXing, even if you're brand new at it.

For about the price of another "Pac-Zapper" game, you can tie your Commodore 64, 128 or VIC-20 into the exciting world of digital communications with the Microlog SWL. $64. Postpaid, U.S.

"When You Buy, Say 73"

Instruction Instructions

Discover hidden savings in the last place you'd ever look — the instruction manual.

Leon Fletcher N6HYK
274 Webster Drive
Ben Lomond CA 95005

Recently I bought an antenna system consisting of the usual four units — tower, antenna, rotor, and rotor control. All the gear is nationally-advertised, widely-used, and highly-regarded by hams throughout the country.

But *every unit* came with printed instructions which had serious errors, omissions, confusions, even contradictions. Indeed, at least one error was an absolute farce.

How serious is the problem of ham gear supplied with instructions which are inaccurate, inadequate, inferior, incomplete, or just plan bungled? Apparently no one knows. At least, a diligent search of ham magazines, handbooks, guides, instructions, and other such publications found no helpful reports, tips, or solutions.

Step 19. Solder C14 as shown in PCB schematic using minimum heat setting on page D-11 of the Owner's Manual 349X not reversing polarity carefully. When done check to be sure D5 was installed first.

Casual on-the-air comments by hams in Washington, Ohio, Florida, Nebraska, California, and other states, however, confirm that poor instructions are indeed a widespread concern.

Ham talk also seems to document that most of us select our gear without giving much thought — perhaps no thought at all — to the effectiveness of the printed instructions which come with our purchases. Yet it is obvious that good instructions can make assembling and operating a unit easy, fast, efficient, and safe — a pleasure to own.

On the other hand, poor instructions can cause delays, waste efforts, spark frustrations, increase costs, produce errors, ruin equipment, and create dangers. In extreme cases, injuries can result.

From my unpleasant struggles with poorly-written instructions have come 10 key questions which can help all hams select their gear more intelligently. Along with these questions are specific examples of poor instructions which accompanied ham gear sold in the past year. By now, however, at least some of these problems — it is hoped — may have been corrected. Therefore, the names of the offending companies are not mentioned.

1. *Can you read the instructions before you buy the gear?*

At any of the current 64 Heathkit® stores throughout the nation you can read the instruction manuals for any of the company's more than 50 pieces of ham equipment, no obligation to buy and no cost, of course. And as the manager of the Cupertino, California, store told me, "Take all the time you need."

Or you can buy a copy of any of Heath's instruction manuals. The cost (a few dollars) is but a modest investment to help you be sure the instructions are effective and that you'll be able to follow them.

On the other hand, when I phoned cross-country to ask a manufacturer of antenna towers for a copy of the instructions for putting up one of its towers which I was considering for purchase, the chief engineer told me, "We don't lend or sell copies of our instructions. You'll get them when the tower's delivered." By then, you are of course pretty much trapped into using the instructions,

bad as they may be; it's clearly not practical to return a tower which can cost several hundred dollars for shipping alone.

2. *Do the instructions make sense?*

Some ham gear comes with instructions that are clearly impractical, unrealistic, even downright foolish. An overstatement? Consider this example.

This farce was included in the 15-page *Instructions for Installation and Operation* for a nationally advertised antenna tower. The purchaser was instructed to lay a concrete foundation on which to raise the tower—a foundation 24 inches square and ten inches deep. That would be a block weighing some 500 pounds.

A few pages later those same instructions told the purchaser that *after* the 480-pound tower was in place on top of that 500-pound foundation: *If tower is out of plumb, shift the concrete foundation block to bring it into vertical alignment, and then backfill firmly around the foundation.*

Can you imagine the struggle to try to prop up one corner of that 25-foot-high, 980-pound mass, or lowering another corner, to get the entire installation sticking straight up in the air?

3. *Are the instructions free of contradictions?*

Instructions which came with one "world famous" beam antenna warned, "Correct assembly and dimensional adjustments are very important to successful operation." Later in those same instructions, the length of one part of an element was stated to be 51 inches; in a table which followed, the length for that same part was given as 50 inches.

Worse still, when I phoned the manufacturer to ask which dimension was correct, I was told, "Ohhh yes...we know about that error. But we haven't got around to correcting our instructions as yet."

Contradicting instructions also came with that infamous tower we've been using as a fine source of poor instructions. On one page the purchaser was told to place "the base hinge plate [which attaches the tower to the concrete foundation] hinge side away from the wall as shown on Detail FB." That "detail," a drawing on the next page of the instructions, showed the hinge reversed, its side *toward* the wall.

Later, those same instructions introduced two contradictions with one sentence. It said the "pulley and safety rest have been inverted so that its [sic] arm will not project outward" during shipping, and therefore "must be reversed as explained below." The instructions "below" never mentioned reversing the pulley; however, that made sense because the pulley arrived not reversed, as stated, but welded firmly in position. And the safety rest, which the instructions said to "reinstall," arrived not installed in reverse, as claimed, but came uninstalled, in parts, unassembled.

4. *Are the instructions free of unnecessary jargon?*

The problem in trying to establish guides for this criterion is that language that is jargon to one person may be perfectly understandable to someone else. Furthermore, the more you read and use jargon, the quicker it may become understandable and therefore acceptable.

The first time I read the *Owner's Manual* for my new rotor control, I was confused by such jargon as "Rec Last," "SCAN then 7," "Counter Clockwise end travel," "access memory location #1," and many other expressions. But at this moment, after rereading the manual many times during the several months I've been using the control, I'm having difficulty finding examples of jargon in the manual; I've finally learned the language.

So try to avoid instructions which are jargon-packed, but also remember that those strange-sounding sentences will probably become clear to you as you reread the instructions and work with the equipment.

5. *Are the instructions specific?*

The instructions for the winch which came with my antenna tower included this great line: *If brake disc mechanism operates intermittently or erratically, brake disc inspection should be accomplished.*

Ignoring that twisted syntax, I searched without success for instructions on how that inspection should be "accomplished." Should I dismantle the winch? Should I look for loose parts, dangling cable, or whatever? *Well,* I thought, *forget the inspection—how do I fix the winch when it operates "intermittently or erratically"?*

No instructions on that, either.

Other nonspecific instructions you should watch out for include such lines as: "Adjust as may be needed." —"Place in a suitable location."—"Tighten as required."

6. *Are the instructions clear?*

The 30-page booklet which came with a nationally-advertised rotor control unit includes instructions not only for the model I bought but for two similar but more sophisticated models.

If the instructions for those other models had been in separate sections of the booklet, there would be no confusion. But this instructional booklet intermixes directions for operating all three units. Often there is little or no indication that the instructions do not apply to my particular equipment. When I first read those instructions, I would suddenly find myself trying to learn how to operate features that were not on my model. Confusing, indeed.

7. *Are the instructions in a logical sequence?*

I haven't found any manufacturer's instructions which say something such as, "But before doing that last step, you must. . ." But some instructions come pretty close to such confusion.

Page 11 of instructions for assembling a beam antenna said to install screws, lockwashers, and nuts on some straps. The instructions didn't state on which side the screws should be placed, yet in later steps the placement of that hardware became critical.

A very serious injury was almost caused by what was left out of another instruction. It said to "mount the balun clip to the circular boss." It did not include a warning that during the mounting the clip might become loose and fly off at a high speed. It did fly off, hit me in the forehead, broke the skin, and caused bleeding; if it had hit me just one inch lower, I would probably now be blind in one eye.

On the other hand, if you want to read instructions which are a model of logical sequencing—indeed, a model of the ideal instructions on almost every criterion—look at a Heathkit manual. Each of the more than 25 Heath manuals I've used starts with an "Introduction," a brief overview of the purpose, use, and features of the unit. Next are tips for "Unpacking," to make sure you do not mix parts intended for one board, for example, with those to be used on some other board. Heath manuals also present "Assembly Notes," hints on tools, identifying parts, soldering, and such.

Then come detailed step-by-step assembly instructions presented in a very logical, clear-cut sequence. There's a check-off system

Judging Instructions for Ham Gear
Check-Off List

When evaluating the instructions which accompany ham gear you are thinking about buying, check off each item below to help you decide if the instructions are effective.

_____ 1. Can you read the instructions before you buy the gear?
_____ 2. Do the instructions make sense?
_____ 3. Are the instructions free of contradictions?
_____ 4. Are the instructions free of unnecessary jargon?
_____ 5. Are the instructions specific?
_____ 6. Are the instructions clear?
_____ 7. Are the instructions in a logical sequence?
_____ 8. Are the instructions free of any "surprise instructions" which may come after you've ordered the gear?
_____ 9. Do the instructions include a phone number you can call for help—ideally an 800 (toll-free) number?
_____ 10. Are you confident the instructions tell you everything you need to know?

to help ensure that you install each part correctly. There are numerous drawings, enlarged drawings of small units or more difficult steps, and photos. Many parts are identified four ways: by Heath part number, circuit component number, electronic values, and by a description of markings.

Final sections of Heathkit manuals present operating guides, procedures "In Case of Difficulty," specifications, circuit description, schematic, and other details. Unlike some other instructions, you'll rarely need to search back and forth through Heathkit manuals for an out-of-sequence step.

8. *Are the instructions free of any "surprise instructions" which may come after you've ordered the gear?*

"Surprise instructions" are such unrevealed details as additional equipment that may be needed, restrictions on use, limitations on locations, unexpected safety recommendations, unmentioned delivery problems, and such.

About a week after I'd ordered that infamous tower—but *before* the tower was delivered—I received in the mail three additional instructions from the manufacturer—details I'd not been told about before ordering the tower.

One instruction was printed in brilliant red on bright yellow paper. Across the top of the page, in letters a half-inch high, was the word "WARNING!" Then came these statements (among others):

- Be sure to check your shipment carefully before acceptance.
- All shipments are made at the risk of the purchaser and (name of the tower) will not be responsible for shortage, loss, or damage occurring in transit.

As fate would have it, the antenna was delivered during a heavy rainstorm. But even without the rain, you can imagine the problem of trying to get a big and busy truck driver to wait as you unpack, count, and inspect some two dozen parts ranging from 20-foot tower sections to 1¼" cotter pins.

A second page of surprise instructions came only after the tower was ordered. It was titled "Duty of consignees to accept freight even though damaged." It presented four long paragraphs of quasi-legal statements claiming that if what I'd ordered was delivered in a damaged condition, I had to accept it no matter what! The final point in those instructions: If the gear arrives damaged, "it is decidedly to [your] advantage to either repair [it] and file claim for cost," or "to sell the merchandise 'as is'" and then "file claim for the loss suffered."

Sure enough, the gear arrived damaged. I phoned the manufacturer and firmly pointed out that while such a provision might be enforceable in the state from which the tower was sent, it probably could not be enforced under the laws of the state in which it was delivered. The manufacturer backed down immediately and sent replacement parts.

Another example of surprise instructions came with a beam antenna. It was not until page 16 of the instructions—just as the antenna was about ready to be raised—that I was told I'd need a 3- or 4-foot mast ("not supplied") to use in finding the "balance point" of the antenna.

While many hams have hefty stocks of such supplies stored at their QTH, I don't. The result can be an unexpected dash to the hardware store, inconveniently and unfairly delaying friends who have gathered to help raise the antenna. A minor point? Perhaps. But why shouldn't all instructions present—right at the start—a list of everything you'll need to complete the project?

9. *Do the instructions include a phone number—ideally an 800 (toll-free) number—you can call for help?*

include this detail. Heathkit instructions always include phone numbers for technical assistance, ordering replacement parts, and such, although they are not toll-free. If the instructions you're evaluating don't give a phone number, there are three steps to getting information you need.

First, of course, phone the store from which you bought the unit. If the staff there can't give you the information you need, then phone the corporate headquarters of the manufacturer of the gear. Ask for "customer service" or "the expert" on the gear which has the problem instructions.

If you still don't get the answers you need, don't hesitate to phone the president of the company. It's been my experience that a surprising number of top executives are readily available and will have the information you need sent to you quickly. Indeed, I find that the president's personal secretary (but often no one less) also will get you answers promptly.

The doubter asks, "What about the extra cost for the phone calls?" Even several cross-country calls cost but a tiny percent of the expenditure you are considering investing in the gear. Besides, you may be lucky: When you call, the key person may not be in, so you can leave a message asking him or her to return the call to you; then the cost is on the company's bill. Presidents, in particular, I notice, generally return calls promptly.

10. *Are you confident the instructions tell you everything you need to know?*

This question is obviously difficult to answer—perhaps impossible—until you are actually trying to follow a set of instructions. Still, there are a few precautions you can take.

First, you can try to find some other ham who has used the gear and ask him or her how complete the instructions are. You might have used another set of instructions, for some other gear, put out by the same manufacturer. Check these; the chances are that if a company has prepared clear-cut, specific, valuable instructions for one of its units, then instructions for

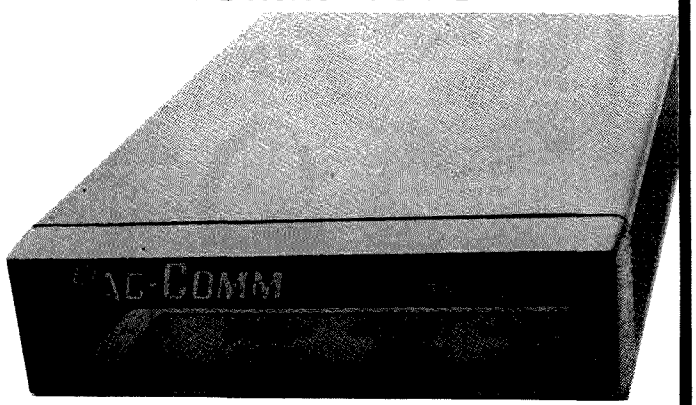
Eucha, OK. 74342 **PH: 918-253-4094**

its other gear are likely to be effective, too.

Another possibility: Compare the instructions with those prepared by another company.

As a last resort, you might ask a salesperson or a manufacturer's representative if the instructions include all the information you'll need. It's not likely they'll tell you about any shortcomings, but if they say, "Yes, the instructions are complete," and you find later that they are not, you may have a bit more clout in trying to get the additional information you need.

In sum, as you consider the purchase of any piece of ham gear, you should be able to answer "yes" to all, or substantially all, of the above questions to help ensure that the instructions for the equipment are effective. If you must answer "no" to more than a few of those questions, you might well shop around for some other unit which may have better instructions.



Realistically, many of us don't want to reject buying a unit just because the instructions are poor. So if you find good gear with poor instructions, you should certainly contact the manufacturer to try to get clarifications.

Still, one key problem remains: Many instructional guides seem clear-cut and easy-to-follow when you're considering the purchase, but later, when you're assembling, installing, or operating the gear, you may face doubts, questions, and confusion.

Unfortunately, shortcomings in instructions for ham gear will very likely continue until hams themselves unite to tell manufacturers that their instructional manuals must follow specific criteria. Until then, we'll have to continue to depend on the ancient Latin proverb, *Caveat emptor*—Let the buyer beware. ■

REVIEW

KANSAS CITY KEYER

Dayton. Lance Johnson had a booth there, on a corner I think it was, and he was hawking a keyer, pretentiously claiming that with it, "CW would never be the same again." I can remember seeing a group of ogle-eyed contest types huddled around the display, listening to the code coming out of a tan box, their fingers twitching and their smiles broadening as Lance led them through his spiel.

The next time I thought of Lance Johnson's Kansas City Keyer was a few hours after a grueling ARRL Sweepstakes. It was grueling because I had spent twenty-four hours flailing away at my ten-year-old Accu Keyer; by hour six, each dit and dah required a supreme effort of will! It was in that quiet, ringing-head time after the contest that I remembered those twitching fingers and broad smiles and swore to myself that, come next test, I, too, would have a reason to smile—my Keyer arrived a week later.

Outside

The Kansas City Keyer comes in an attractive two-tone tan box which is about four and a half inches wide and seven inches deep. There are two LEDs, a green one for power and a red one marked "Status," which monitors the machine's reaction to what you are trying to do. To the right of the LEDs is a rotary pot that serves both as an on-off switch and an analog speed control. The rest of the front panel is taken up by a sixteen-button touchpad (0–9, A–D, *, and #) which you use to access the Keyer's functions.

The rear panel is home to two RCA jacks, used for either positive or negative keying voltage, a momentary-contact Reset button, a DIN jack for connecting the Keyer to your paddles, and a miniature phone jack for power (8 to 18 volts dc).

Inside

The true beauty of the KC Keyer is evident when you pop the cover. What you get in there is a powerful microprocessor dedicated to one job—managing your CW. The micro is a Rockwell 6502, a very popular and flexible chip found in many single-board computers (including the successful Apple II). Three chips are used in supporting roles: a 6522 Peripheral Interface Adapter, a 4K EPROM for program storage, and a 6116 2K SRAM for on-line memory. A handful of discrete components and SSI chips completes the hardware. The PC board is plated, double-sided, and obviously laid out by a professional.

Is there any advantage to using a general-purpose microprocessor for this sort of job instead of gates and clocks? Yes! Two advantages, in fact. The first is a reduced parts count—all of the gates and timers found in the last generation's keyers can be implemented in software. Of course, the program to do this may be quite long, but memory is so cheap today that program size can be discounted as long as the coding is efficient.

The second advantage is that a keyer in software can do anything that you want it to! Want automatic serial numbers? Fine, just write a few program lines. Need translation from Morse to International code? No problem, just add a lookup table. You get the idea. An additional plus is that upgrades are as easy as swapping a single EPROM. Power On!

Now we know what the KC Keyer looks like and what's inside it, but what can it do? When the power is turned on, the Keyer will be in its default configuration: speed at about 15 wpm, standard weighting, and automatic character spacing. The fourteen message buffers will be empty and the automatic serial number will be set to zero.

Programming is accomplished via the sixteen-button keypad. Each pushbotton has an assigned function which is assessed by pressing the * key. For example, pressing the sequence * Speed 2 5 will set the speed to 25 wpm. Speed is above the 2 on the keypad. A short beep is output through the internal speaker to confirm each keypress.

One small gripe about the speaker: There is no provision to disable the sidetone from the keypad. The beep is handy to have during the programming steps, but after about ten minutes of CW it becomes annoying. I ended up permanently disabling the sidetone by clipping the wire off the speaker. It would have been better, I think, to have used the rotary pot as a volume control rather than an analog speed control.

The Buffers

What really sets the Kansas City Keyer apart from other memory keyers on the market is the way the message buffers are set up. There are fourteen of them, 0-9 and A-D, and you can partition the 1500-character memory among the buffers any way you like. Text is entered by sending CW to the keyer after specifying which buffer is to hold the information. An "editor" of sorts is available in this mode; if you make a mistake, a string of eight dits will erase the current word and play back the word before it. Perfect word spacing is as simple as watching the red Status LED: At the end of each word, wait for the light to flash before entering the next code group.

Now for the really *good* stuff! You can at any time during text entry add a Wait command. When the command is encountered during transmission, the keyer will stop sending until a character or word is sent manually from the paddle. Say you have buffer A configured like this: TEST DE KW1O (WAIT) TU 5NN NH K. When message is selected, the Keyer will send TEST DE KW1O and stop. Now send the call of the responding station on your paddle: KM1C. After the C, the KC Keyer will continue with the message in buffer A: TU 5NN NH K.

You also can chain buffers together. Let's put TEST DE KW1O (WAIT) (B) in buffer A and TU 5NN NH K (WAIT) (A) in buffer B. Selecting message A will put the Keyer into a loop of calls and answers; if no one responds to your CQ, just select A again.

Automatic serial numbers are available, too. Add a pound sign (#) to your message for this option. I use one buffer for answering the inevitable requests for repeat—it DECrements the serial number and sends the exchange again. The number can be set at any time directly from the keyboard, and pressing the pound sign by itself will cause the Keyer to send the current serial number (be aware that doing this will also increment the number).

Remote Buttons

Any one of the features I've mentioned so far would have convinced me that the KC Keyer was in a class by itself, but Lance Johnson was on a roll! They decided that it would be neat if four of the message buffers were available remotely. What they designed was a little bracket made to attach to a Bencher paddle that brings out buttons A, B, C, and D. (I also tried it out on a set of Nye paddles—it fit without modification.)

This means that you can program buffers A-D with the appropriate information and operate an entire contest by pushing little buttons on your paddles! I do this with my left hand; my right hand is free to log and dupe. There's plenty of time for paperwork as the Keyer is busy sending the exchange.

The Keyer has a provision for battery backup. At first I thought that was odd, but I soon found it indispensable. I happened to have a couple of students who were learning Morse code. It was very easy for me to rattle off ten or fifteen minute's worth of practice into a buffer at 30 wpm at home, then take the Keyer to class and play back the material at 5 wpm. The Rate function let me set the character speed at 13 wpm, a method used by most instructors.

Last Words

Obviously, I like the Kansas City Keyer. I think you will, too. It is expensive—about $200—but what you get is a flexible CW computer that does things you can only dream about with your present machine. The manual is *very* good, and a newsletter comes out now and then which features programming tips and modifications.

If you are *serious* about CW, get in touch with *Lance Johnson Engineering, PO Box 7363, Kansas City MO 64116*.

ISOTRON SOLUTION FOR THE 160-METER BAND

Since the opening of the 160-meter band to amateur use, the 1.8-band-selector position on my FT-102 has been gathering dust. Like a number of hams, I simply do not have space to put up a 252-foot-plus wire antenna for 160 meters. Even if space was available I doubt if I would consider a wire antenna because of the difficulty I had in getting permission to put up my 5-band vertical at my apartment. It would be nice if there was a zero-space antenna for the 160-meter band!

Baltimore, Maryland, is approximately 500 miles from my QTH, and my contact with WB3GBF on 40 meters opened my eyes to the signal power of the Bilal Isotron antenna. My RST using a 5-band

vertical was 5–9 while WB3GBF's RST, using an Isotron 40-meter antenna, was 5–20 dB over 9. And to top this, he was using it inside his apartment.

As an ARRL Assistant Technical coordinator for North Carolina, N4BTK asked me to help him with his 20-meter-antenna problems in a local Senior Citizen retirement apartment complex. John lives on the 12th floor and had been using a coil-loaded window antenna but for some reason, 20 meters, even at the altitude of a 12-story building, was very weak. I suggested an Isotron 20-meter antenna as a better solution since the management would not permit a vertical or beam to be mounted on the roof. John's Isotron 40 was mounted 3 feet from the apartment's windowsill on an offset 1"-mast section. By comparison, it out-performs my 5-band vertical on 20 meters.

Impressed with the two-band performance of the Isotron antennas, I contacted Ralph Bilal WD0EJA about his 160-meter antenna and proposed that I work with it to obtain details for an article. My thought was that perhaps only an Isotron could give me 160-meter operation in my apartment complex, and this was an opportunity for me to see what it could do.

The Isotron antennas come in a kit form that can be fully assembled in less than an hour using only a screwdriver and 7/16" socket wrench (Photo A). They are definitely unique in that no frequency model occupies more than an area of 1.5' x 2' x 2.5', and most frequencies even less. Technically speaking, they defy the accepted antenna theorem of voltage and current distribution on a dipole antenna. One cannot help being impressed when seeing an Isotron in operation.

Assembly begins by attaching a formed aluminum plate to the insulated top support member. In my assembly of the 160-meter antenna, I first installed the mast clamp, U bolts in the end of the insulated bar and attached it to a mast section. This method supports the insulated bar while you attach the formed metal plates.

I followed the same method to mount the square metal lower support section to the mast for attaching the lower formed metal plate. Since the top and bottom plates are aluminum and will quickly oxidize, I spread a thin film of No-Ox over the surfaces that would overlap when bolted to the support bar.

No-Ox is a common non-oxidizing compound used to prevent aluminum oxidization of electrical wiring and is usually available at most electrical supply houses. After attaching the top and bottom formed plates, my antenna looked like bird wings, one above the other (Photo B).

The rather large antenna coil is attached between the top and bottom support bars by adjustable bolts Inserted in the top and bottom sections of the coil. I inserted both bolts and loosely positioned their lock nuts so that final centering of the coil could be accomplished with minimum effort. I attached the top of the coil to the top insulated support bar first and ran the coil's bottom bolt through the bottom support without attaching the securing nut. This was to permit attachment of the two plastic side panels without first adjusting the position of the lower support bar attached to the assembly mast.

At this point of the antenna's assembly, only the 1/4–20 bolts holding the formed metal plates to their respective support bars had been tightened securely.

There are two transparent plastic side panels to be attached to the top and bottom formed plates. One plastic plate contains a terminal. After loosely attaching the top ends of the two side plastic plates to the top plates, loosen the bottom support bar mast clamp and gently raise or lower the bar until the side plate holes line up with the bottom plate's holes. Insert the 1/4–20 bolts. At this point, all 1/4–20 bolts joining metal to metal may be tightened securely.

Those 1/4–20 bolts connecting the side plastic plates to the metal of the top and bottom plates should be tightened with less force than the metal-to-metal bolts to prevent shattering of the plastic. These bolts may be finger-tightened if used in connection with locktite or other thread-locking compounds.

Centering the coil between the top and bottom plates is not difficult. Merely measure the distance between the bottom and top ends of the coil to their respective metal plates—not the support bars. There should be some tension put on the top and bottom formed plates by the coil's bolts that will pull the formed plates in slightly. This increases the rigidity of the plates to eliminate wind flutter and subsequent detuning of the antenna. (See Photo C.)

Pre-soldered wires with closed terminal ends connect the PL-259 antenna cable connector to the coil's top-end winding and the top formed plates. A second closed terminal from the PL-259 connector connects to the coil's bottom-end winding and to the bottom formed plates (see Photo D). The resulting electrical circuit is a simple LC series circuit with the top and bottom plates forming the plates of a capacitor connected in series to the coil.

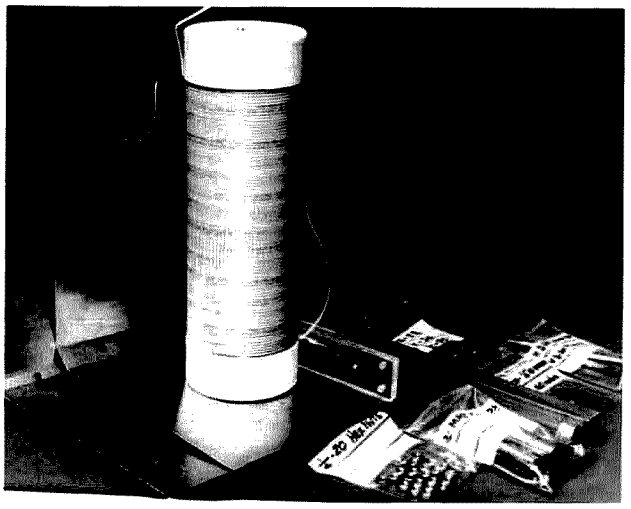

Photo A. The Isotron 160 kit.

The final assembly consists of two threaded L-shaped rods on which two small rectangular aluminum plates are attached (Photo B). It would be advisable to round all edges of these plates with a file, including each corner, before attaching to the bolt. This will reduce rf-energy discharge into the atmosphere.

The actual antenna assembly is basically an easy push-in-a-bolt-attach-a-nut operation. At worst, it takes no more than an hour. The hard part comes in the final tuning of the antenna. This is done by moving the tuning plates on the L-bolts until the lowest swr ratio has been reached.

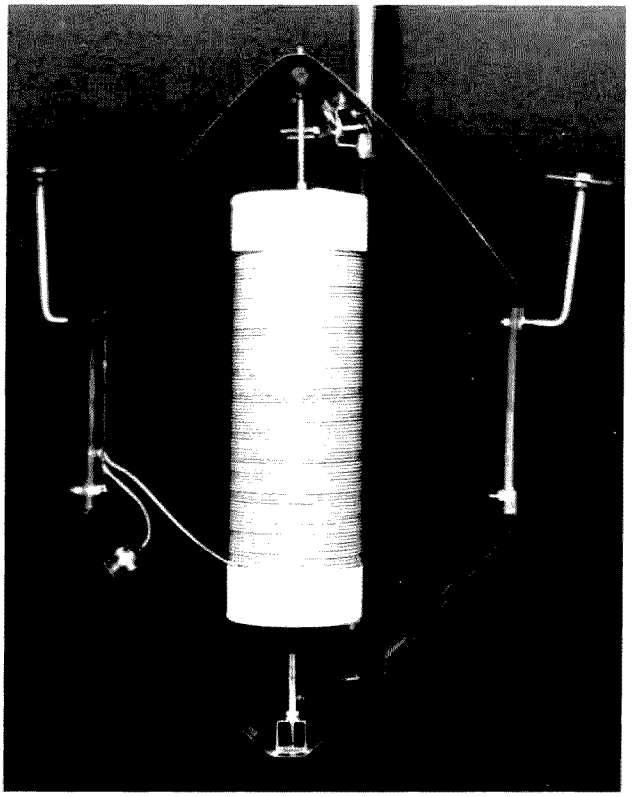

Photo B. The Isotron 160 assembled.

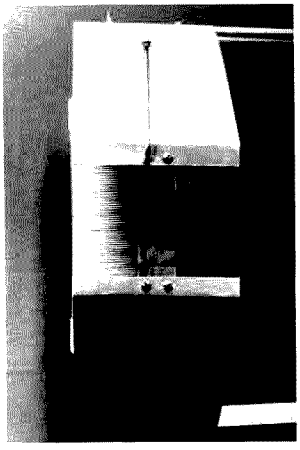

Photo C. Side view. The plastic holds the upper and lower wings together under slight tension.

This will be a trial-and-error approach where you select your transmit frequency, and, at the transmitters lowest power level, tune the finals to resonance and note the swr indication. Now turn off the transmitter and make a very slight change in the positions of both tuning plates. Turn on the transmitter and recheck your swr. This procedure is repeated until the swr lowers to between 1:1.5 and 1:2.0.

The Isotron 160-meter antenna produces such a strong rf field at 100-Watts input that it is unsafe for indoor use. It is best used outdoors at a height above ground where no one walking by could possibly reach it and suffer rf burns or shock.

The advantages of the Isotron antennas are small physical size, no ground-plane radials required, and minimal parts, for trouble-free operation. Its radiation patterns are typical of ground-mounted vertical antennas when it is connected to ground by an 8-foot-copperclad ground rod. The only disadvantages are tuning it and a somewhat narrow bandwidth.

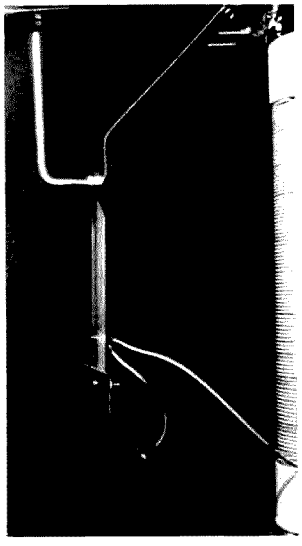

Photo D. One of the tuning plates.

I believe that a remote tuning system, using plastic components and nylon or monofilament control lines, could be added to the tuning L-bolts that would enable the antenna to be remotely tuned under power to eliminate the present difficulties when frequencies outside of the antenna's bandwidth are wanted.

I visualize connecting the two L-bolts together with a small plastic rod which could be moved forward or backward by the movement of the line in the manner that a pointer on a radio-tuning dial is moved by the dial cord. Another approach would be to use two control lines so that each tuning plate's bolt could be moved independently by a dual-cord system.

I do not know if atmospherics or lack of 1.8 MHz activity in my area was the reason I made no 1.8 MHz contacts in the period I had access to the antenna. I do know that it boosted the background noise level from zilch to S-9 on my FT-102.

James A. Grupton, Jr. KF4PW
Charlotte NC

USER'S REPORT

Ralph Bilal gives you a complete set of instructions for tuning his antennas, and the 160-meter version is no exception. I placed the antenna on a seven-foot mast at ground level and began the preliminary tuning procedure using an MFJ antenna-noise bridge and the station receiver. The antenna is designed to be resonant, as received, just above 2.0 MHz, and Ralph recommends that you try it out under low power to check your swr at a frequency just below the top band edge.

The antenna environment at ground level will make a difference in your results because of antenna capacity to ground and to nearby objects. I supported it temporarily with one of those umbrella tables with a hole in the center. This one was aluminum, and I knew that it would affect the antenna resonance point somewhat. Sure enough, it resonated a bit above 2.0 MHz, but I was able to add the small tuning rods provided and achieve resonance at about 1950 kHz.

There are two rods, one mounted on each side of the antenna at the top plate. Bringing them down from the vertical to the horizontal by simply rotating them on their mounting hardware and retightening them, lowered the resonance to below 1900 kHz. I reasoned that this was close enough for now, and that by mounting the antenna on the roof I would be able to lower the resonant frequency still further.

Incidentally, it would be good to point out that *any* antenna which is only a small fraction of a wavelength in size and consists of "lumped" values of inductance and capacitance, will necessarily have a limited-frequency bandwidth, so I did not expect to be able to cover the entire band with one setting. As it turned out, I was able to cover only 25 kHz either side of resonance without retuning the antenna, but that's getting ahead of the story.

So far, things were going according to plan, and the moment of truth had arrived; it was time to install the Isotron 160 on my chimney mount, up in the clear and away from surrounding objects—or at least as far as possible considering that my "antenna farm" is a hole in the midst of trees, with the nearest being about 25 feet away.

Another point: I prefer antennas that are tuned to resonance at the antenna and not in the shack by means of a coupler or antenna tuner. In other words, I like to bring the coax directly to the transceiver and not have to go through any sort of matching device to make it work. This requires that the antenna itself be properly tuned.

It took only a few minutes to mount the antenna to the chimney bracket and secure it for testing. Since I happened to have RG-59/U available (instead of the RG-58/U which I prefer) I used that, and connected it to the chassis-type connector on the antenna. Tuning up the rig was easy, and the antenna accepted power readily at 1900 kHz—but not at 1850 where I wanted to center it. Back up to the roof again to adjust the tuning rods; down the ladder to the check and another tune-up. After about three trips, I got the antenna to resonate at 1860 kHz—close enough for government work, as they say.

And Now, For The Test

It was necessary only to wait until dark now to test the antenna—a time when I knew that there would be stations available for contacts. As it turned out, I could have done my on-the-air tests right away because there was a contest in full swing! Nevertheless, I did wait until about 2130Z, and began to tune the band.

There was plenty of activity. Normally, I prefer CW operation, but in testing this antenna I reasoned that SSB should be a more difficult evaluation mode because the antenna would really have to put out a good signal to compete with the stations using full-size antennas for this top band.

Tuning, tuning. . .oops, here's one: *"CQ Contest, CO contest, from VE1ASJ, VE1ASJ, Contest, K."* Frequency 1823 kHz. Quick, now.

"VEQASJ, VE1ASJ from W1XU, W1XU, New Hampshire. Over"

"W1XU from VE1ASJ; five nine of hive, OSL?

"VE1ASJ from W1XU; OSL and thanks, OM. Five nine oh five. Good luck in the contest." Wow, the antenna worked into the Maritimes!

In quick succession, I worked VE3OME (Ontario) and VE2DVI (Quebec) with 5/9 signal reports. Then, I happened upon K2LXN and KA1W; Connie in Parish, New York, and Dave in Bridgeport, Connecticut, having a nice QSO. Calling KA1W, Dave came back with a *"Five nine plus 10 dB, here in Bridgeport OM. Nice signal; how do you copy W1XU, Connie? K2LXN from KA1W."*

"W1XU, with KA1W, here is K2LXN. Nice signal OM in Parish, New York. Five and nine on a noisy band. How do you read me? Over."

"Thanks lot, gentlemen. This is an experimental antenna, and I really appreciate the reports. You're both doing well here through a lot of QRN, and both well above S9. Good chatting with you, and so long from Peterborough, NH. Name is Jim, and I'll be looking for you on 160 again. Seventy three."

Great stuff, this antenna really seems to get out. Frequency was . . . hmm, let me see . . . 1850 kHz. Not bad at all. A little later I heard W3GFR calling CQ at exactly 1850 kHz. There—he's signing.

"W3GFU, W3GFU, W3GFU, here is W1XU, W1XU, Whiskey One X-Ray Uniform in Peterborough, New Hampshire. Over."

"Roger, Roger. W1XU from W3GFU right back. Thanks for the call. Name here is Jim and the GTH is Churchville, PA near Philadelphia. Your signal is five by nine here, with some QSB. How do you read me? W1XU from W3GFU, over."

W3GFU from W1XU. Hi, Jim, good to hear you. My name is Jim,

too, and you're coming through just great; also five by nine here in Peterborough, New Hampshire. I'm running about 100 Watts to an experimental antenna, and would like to see how it goes for a few minutes."

These exchanges lasted for 45 minutes, and during this time I learned that Jim was transmitting on an inverted vee dipole at 40 feet and had a TS-830S (I was using my TS-820S) at about the same power output. His receiving antenna was a coaxial loop, about five feet on a side and rotatable. Although the received signal strength was down a bit on the loop antenna, Jim reported the signal-to-noise *ratio* was better, and he planned to install an amplifier to improve the signal.

When I described my own antenna, Jim was enthusiastic and wanted to know more. He remarked that it ought to be ideal for an apartment dweller, a condo owner, or someone in a travel trailer—virtually anywhere a full-sized antenna couldn't be used. Naturally (with great satisfaction) I agreed.

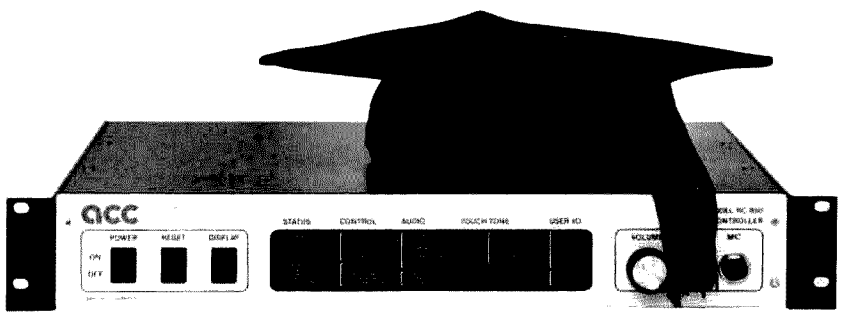
During the course of the conversation, Jim said: *"100% copy; really amazing! Really hard to believe that it works that well. You're doing a job—and as good as many of the signals I hear from guys running the same or even more power on big, outside antennas. The guy who designed that antenna must be a pretty smart cookie."*

And so it went. Other contacts have been as rewarding, too. On CW and phone, the Bilal Isotron antenna performs very well, indeed—perhaps much better than I had any right to expect. I've had fun with it, but can't claim that under all conditions it will out-perform a big antenna. That would be ridiculous. However, I can recommend it for the ham who needs to operate 160 meters but can't put up a larger one.

Make no mistake, it is a bit fussy to tune, and you're going to have to be patient and take your time with it. The bandwidth in my case is about 50 kHz either side of resonance between the 2:1 VSWR points. Ralph's antenna, which is at 40 feet and tuned to perfection, gives about 100 kHz between the 2:1 vswr points on either side of resonance.

As a last measure, I went up on the roof and painted all of the critical connections with weatherproofing—because I plan to leave it up this winter and enjoy 160!

By the way, I did hear some DX coming through—faintly, but it was there. No hope, of course, to contact it with the Isotron . . . or is there?



Jim Gray
***73* Staff**

MMT 144/28R TRANSVERTER MICROWAVE MODULES

I love transverters. I've got six of them right now for various assorted purposes on four different bands driven from three different radios. Not surprisingly, five of the six are made by Microwave Modules of Liverpool, England, long the biggest maker of transverters for sale in this country (and perhaps the world as well). MM has long made a quality product allowing transmit and receive conversion of 28-MHz signals to 50, 144, 432, and 1296 MHz, as well as 144 MHz to 50, 432, and 1296 MHz. They even have a model that allows operation on 28 MHz from 144 MHz. Talk about covering all the bases!

Naturally, I was excited to hear about the new line of MM transverters for 1985, which feature GaAsFET front ends and 25 Watts output. In addition, the new models claim input sensitivity as low as 1 mW for rated output. At this time, the only model available in this country is the MMT 144/28R, and I was able to obtain a sample for review from the US importer, the "PX" Shack.

The MMT 144/28R is a handsome unit, as shown in Photo A. This is a big departure from the old black-box approach to transverters—i.e., you set 'em and hide 'em away. With its LED bar-graph power display and attractive faceplate, this unit demands to be set out on your operating desk. MM has retained the rf VOX-type keying of previous models, where your 28-MHz signal actuates the

The RC-850 Repeater Controller just got a whole lot smarter.

Our new Version 3 software makes the best repeater controller **EVEN BETTER.**

The autopatch now supports remote telephone lines linked by radio, so that you can extend your autopatch coverage to match your RF coverage. You can have autopatch even if you can't get a phone line at your site. The 250 autodial numbers meet the needs of even the largest groups, with up to 35 digit storage for MCI and Sprint.

The easy-to-use Electronic Mailbox lets you include phone numbers, times, or frequencies as parts of messages. And it's so smart, it'll leave you a message if you miss a reverse patch, or if an alarm condition occurs.

Selective call and signalling capabilities range from two-tone sequential to numeric display paging, so you'll always be available. And its voice response metering is enhanced to continuously store low and high readings – so you can find out how cold it gets, how high the reflected power reads . . . and *when*.

Of course, a controller so feature-packed gives you secure control. Individual user access codes, with user callsign readback, can control access to selected functions to completely prevent horseplay.

ACC's amateur radio controllers are anything but "amateur". They're used by the U.S. Army, Navy, Forest Service, and other government and commercial users around the country. But, of course, you'll also find them on the leading amateur radio repeaters in North America and abroad.

There's never been a better time to upgrade your repeater system with an ACC controller, unmatched anywhere in quality, sophistication, and performance, with documentation and support to match.

Please call or write now for the rest of the story on all our repeater products, including controllers, digital voice storage units, and other Touch-Tone control products.

You'll be GLAD you did.

acc advanced computer controls, inc.

10816 Northridge Square, Cupertino, CA 95014
(408) 749-8330

transmit section and the drop-out is determined by the front-panel potentiometer.

The rear-panel connections are similar to earlier MMTs. They have retained the 5-pin plug for power and keying. Also included are UHF connectors for 28-MHz transmit and receive signals, as well as a single UHF connector for 144-MHz antenna. This latter departs from previous designs as there is no provision for a separate 144-MHz-receive input, mandatory when using a tube-type amplifier and SPDT relay. (It's my understanding that the factory will make this option available on future models.) It would appear that hams in Great Britain (and possibly the rest of Europe) are accustomed to the transceive operation this unit offers. Most solid-state amplifiers use rf VOX keying also, and allow a single connection to the driving source, switching the amplifier in and out of the line.

Also on the back panel is a small access hole for adjusting the input-drive level. Those familiar with the older MMT units will welcome this access hole, for in the past you had to remove the top cover to set the drive level. The control complement is rounded out by the front-panel power switch on the left and the multifunction switch marked FREQUENCY SHIFT.

This switch also is a departure from previous models. What it does is to incorporate an offset oscillator into the transmit circuit so that you can work repeaters with your FM-equipped HF transceiver. Only the -600 offset is supplied as this is standard in Europe. With the switch in the NORM mode, your transmit signal is offset -600 kHz. In SIMP position, transmit and receive are the same. In REV position, your receive frequency is offset −600 kHz from the transmit frequency. This is similar to what we call a +600-kHz offset here, except we offset the transmit frequency instead. At this time, there is no provision for +600-kHz offset in Europe, so this switch functions as a repeater reverse switch.

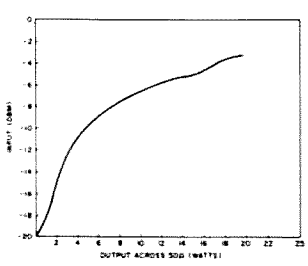


Fig. 1. Input drive vs. output power at maximum sensitivity.

Photo A. The MMT 144/28R transverter.

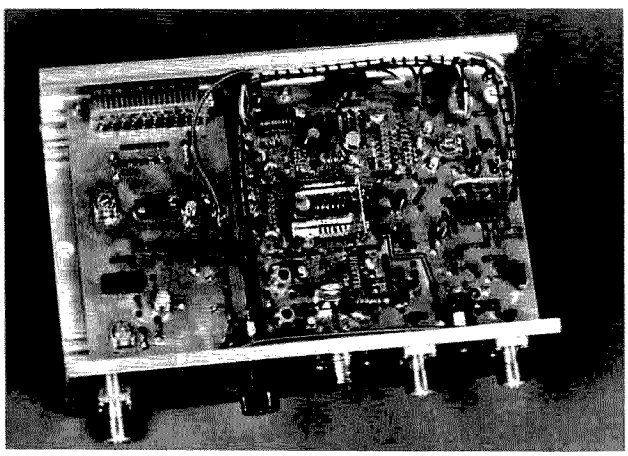

Photo B. Top view with cover removed.

One additional control I'd like to see is the addition of another switch to allow bandswitching the coverage from 144–146 MHz to 146–148 MHz. Ivars Lauzums KC2PX of The "PX" Shack says that this option is being studied and future units may be so equipped. As the unit comes, however, you can work FM simplex and access repeaters in the 145-MHz region using the standard −600-kHz offset. Of course, you could also replace the LO crystal with a 118-MHz unit and the offset crystal with a 117.40-MHz unit to allow this, but you'd give up use of the SSB and CW segments. Hence the request for a bandswitch.

The unit was put into service immediately and a marked improvement was noted on receive signals. The GaAsFET is not rated as far as gain goes, but initial tests over the air indicated it was at least 2 dB better than the standard MMT 144/28R, as far as noise figure goes. (We'll substantiate performance claims shortly.) The receiver displayed good performance in the presence of strong local adjacent signals, such as stations S9+60 dBm, 10 kHz away. Measurements bore this performance out in the lab.

Driving the unit with my ICOM 740 resulted in 23 Watts output power across 50 Ohms at 13.8 volts dc. I could not increase this output to the rated 25 Watts, and the input mixer appeared to be saturated at the given drive level. Subsequent conversations with Ivars resulted in the adjustment of the internal ALC circuit, which then yielded 25 Watts output. In fact, with a Bird 50-Ohm termination, I was able to increase output all the way up to 28 Watts but set it back to 25 which is more than adequate for my requirements. Since I use both solid-state and tube-type amplifiers, I need only 1 to 3 Watts of output and a step attenuator in series with the 28-MHz transmit input. This is switched out for QRP use or for driving a solid-state amplifier.

One peculiar problem cropped up early: After keying the circuit several times, it locked up in transmit. However, with the FREQUENCY SHIFT in NORM or REV, I was able to unlock the unit. Soon, however, these positions locked up as well. Careful study of the schematic resulted in clipping a diode to the offset oscillator circuit, and that did it. I was back on the air. It seems that the quad op amp LM324 used to effect the switching of the offset oscillator schemes blew up for some strange reason—perhaps none other than it was a defective chip. I replaced it with a new chip and installed a socket in case of future trouble, which hasn't occurred. This is a quirk the manufacturer is looking into.

After spending many hours working SSB and CW, I fooled a bit with the offset oscillators and worked several repeaters in the area in the 145-MHz range, getting excellent signal reports. Of course, this is no way to measure linearity, especially on FM! So, after arrangements were made, we trucked the units off to a local test lab to make some honest-to-Abe measurements using sophisticated equipment.

For the bulk of our tests, we em-

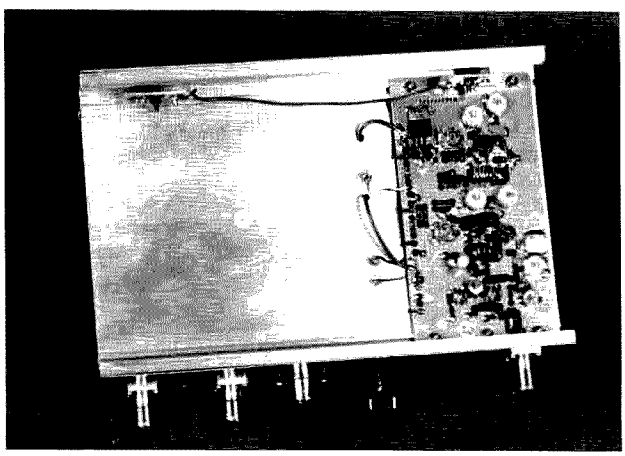

Photo C. Bottom view with cover removed.

ployed a Hewlett-Packard 8640B generator and 8554-141T analyzer. No noise-figure measurements were made, due to the lack of the right test equipment. The first test we ran was receiver conversion gain, claimed to be 22 dB ± 1 dBm by the manufacturer. We measured 19 dB at 144.0 MHz and 20.8 dB at 148 MHz. (A second unit measured 21 dB at 144.8 MHz.)

Sensitivity was found to be 0.07 uV for 10 dB S+N/N (−130 dBm)—more than adequate. In fact, excellent! But the associated problems of receiver crunching in the presence of a strong signal often come with high gain and sensitivity figures.

How did the MMT 144/28R do? We calculated the 1-dB compression point to be +6 dBm, which is very good for a GaAsFET front end. As a reference point, another manufacturer of preamplifiers in Europe sells a 144-MHz GaAsFET preamp with a 1-dB compression point of −4 dBm, indicating that likely it would have trouble with relatively strong signals encountered in everyday operation.

We found that the transmit section is relatively linear, although saturation occurred with an input of .4 mW for 17 Watts output. Fig. 1 shows input drive vs. output power. These tests were made using the signal generator directly into the 28-MHz input, and the output of the transverter terminated into a Bird 50-Watt Termaline resistor, and power was measured on a Bird 43 with 50-Watt 100–250-MHz slug installed. The second harmonic was down −48 dB from the reference signal, and the third harmonic down in excess of −60 dB. No spurs were evident. The transmit section complies easily with FCC regulations. These measurements were taken at both 10 Watts and 15 Watts output.

To anticipate your next question, we didn't measure gain of the front-end rf stage. But as you can see from the sensitivity and compression-point data, the front end is more than adequate for weak-signal work. This is one transverter that doesn't need a preamp in front of it. In fact, such a scheme would lead to degradation of the receiver performance, and unless you are trying to overcome 10 dB of feedline loss, I wouldn't recommend it.

Incidentally, the transverter uses a GaAsFET to drive the diode ring mixer, which helps dynamic range considerably over an active mixer. This is a common scheme

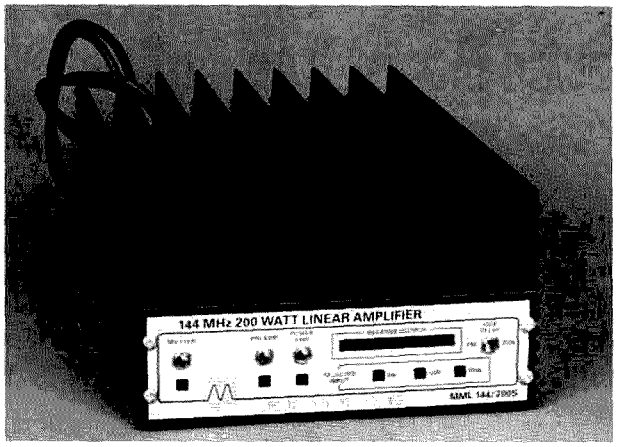

Photo A. The MML/200-S, 200-Watt, 144-MHz power amplifier.

on the newer HF transceivers and there's no reason why it can't work at VHF, either. It would appear also that MM has tamed the GaAsFET and made it a valuable addition to the VHF station. Based on actual over-the-air tests, I'd guess that the noise figure is probably under 1 dB with room to spare.

To sum it up, the MMT 144/28R represents a real step forward for the transverter user—not just in performance but in appearance and flexibility as well, what with the additional offset oscillators for FM work. The power output is sufficient for QRP work or for driving a higher-power amplifier, especially the newer grounded-grid types using 3CX800 tubes. These amplifiers typically need 20–30 Watts to attain full output, which has been a problem with the earlier transverters. Now you can set aside that intermediate amplifier!

Discussions with Ivars also reveal that some models of the MMT 144/28R can make as much as 45 Watts output with the ALC shut off, but this is risky operation. Surely the circuit can tolerate 30 Watts output, which is safely within the drive requirements of the 3CX800.

As regards the output, the heat sink is simply a thick piece of aluminum to which the PA stage is bolted. This piece of aluminum is contained within the transverter and appears to do a sufficient job of drawing off heat, but I'd still prefer an external heat sink that could be air-cooled—especially on a hot day!

The MMT 144/28R is available from *The "PX" Shack, 52 Stonewyck Drive, Belle Mead NJ 08502.* Price class: $350.

Peter H. Putman KT2B
Morris Plains NJ

POWER AMPLIFIER/ MICROWAVE MODULES

Many readers are familiar with Microwave Modules transverters and receiving converters. But MM also manufactures a fine line of solid-state rf power amplifiers for the VHF and UHF spectrum which are very popular in Europe. Continuing along these lines is the new MML/200-S amplifier for 144 MHz, with several interesting features.

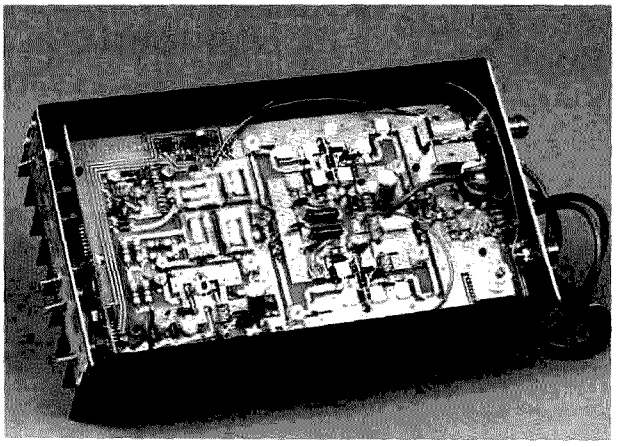

Photo B. Underside of the MML/200-S showing input-selector switch, lower right.

First of all, the heat sink is massive. This is one of the few high-power rf amplifiers I've seen that really can hold its power! It's big, all right, but you can still fit it in the trunk of your car, should you desire to go mobile. Front-panel layout is uncluttered, with separate switches for MASTER POWER, PREAMP ON, POWER AMP, and VOX DELAY. A front-panel LED bar-graph indicator shows relative output, and three other LEDs show the input mode selected (see Fig. 1).

A word about the input mode: MM has come out with a truly universal amplifier, and the user can select input sensitivity ranges of 25, 10, or 3 Watts. Now *that's* flexibility! Everyone from the FT-290 user to an IC-271 can run 200 Watts now with the same amplifier. The selection is made using a standard screwdriver to rotate a switch through a hole in the bottom cover in the rear of the chassis. In the 25-Watt position, the finals are driven directly. In the 10-Watt position, the driver comes into play with a fixed 50-Ohm attenuator ahead of it, and in the 3-Watt position, the input signal goes straight to the driver.

The transistor line-up features Thompson-type SD1275 in the driver with a pair of SD1477 finals operating into a hybrid Wilkinson power combiner. The gain of the final stage is 10 dB.

Fig. 2 shows the bottom of the amplifier and the PC board with the cover removed. Also included is a 12-dB GaAsFET preamplifier which is switchable from the front panel and is automatically switched when transmitting. The rf VOX circuit determines the drop-out delay, and is used only when the rf-sensing circuit comes into play. In my station I prefer to hard-key the amplifier through the rear-panel RCA jack, which is grounded for transmit.

Performance! Performance! I hear you screaming! Hold onto your hats, for this unit really makes the grade. Initially, I evaluated the receiver preamp section with Steve Katz WB2WIK, using Hewlett-Packard 8554-141T analyzers and an H-P 8640B generator. MM claims 12 dB of gain and deliberately minimized gain so as to not overload the front end of a multimode transceiver which would be used with the preamp. Good move!

This, of course, keeps compres-

25-Watt Range (Swr calculated at 1.75:1)

Fig. 1. Power-output tests. Drive source: ICOM 740 driving MMT 144/28R with step attenuator on 28-MHz transmit line. Dc power: ASTRON Model RS-35 35-Ampere, 14.0-volt regulated dc supply. Input calibration: Bird Termaline 25-Watt coaxial resistor. Output load: Cushcraft 32-19 Boomer (Type. Imp. 50 Ohms at 144.150 MHz). Input and output measured with Bird Thruline 43 wattmeters using 5-, 10-, 50-, 100-, and 500-Watt slugs. Input drive first calibrated into dummy load, then applied to MML 144/200. Input and output measured simultaneously. Dc voltage monitored, dc amperage unknown.

sion point high and also helps dynamic range. In our tests, we verified the gain to be 14 dB—a bit higher than claimed, but useful. The 1-dB compression point is +6 dBm, very good for a 144-MHz GaAsFET. This means the MML-200-S preamp will hold its own in the presence of very strong local signals. Sensitivity was calculated to be −124 dBm at 10 dB S+N/N. The minimum discernable signal (MDS) was −133 dBm.

Now, on to the power measurements. For these tests, I used an ASTRON RS-35 power supply set at 14.0 volts. The driving source was an MMT 144/28R transverter, excited by a Kenwood TS-430S. A step attenuator was put in line from the TS-430 to the MMT 144/28R. Next, I ran the output from the transverter through a Bird 43 wattmeter, using 5-W, 10-W, and 50-W slugs for calibration. Finally, the input went through a coaxial switch to either a 25-Watt Termaline load for calibration or the amplifier.

The output of the MML 200-S was monitored using a 50-Ohm load and Bird 43 with 100- and 500-Watt slugs. The reason I put the coax switch at the input with the dummy load is that inputs to solid-state amplifiers usually don't look like 50 Ohms, so my readings would have been falsified. Fig. 1 shows calibrated input power, measured input power, and output power in the 3-, 10-, and 25-Watt positions.

One thing that becomes evident right away is that the input to the final amplifier stage is not 50 Ohms. In fact, it calculates out to about 85 Ohms! That's not surprising in view of what I stated earlier. Remember that in this mode, your input signal drives the final stage directly. In the 10-Watt stage, the swr is excellent, but this is due largely to the resistive pad employed at the input to the driver. Here, calibrated and measured readings agreed each time.

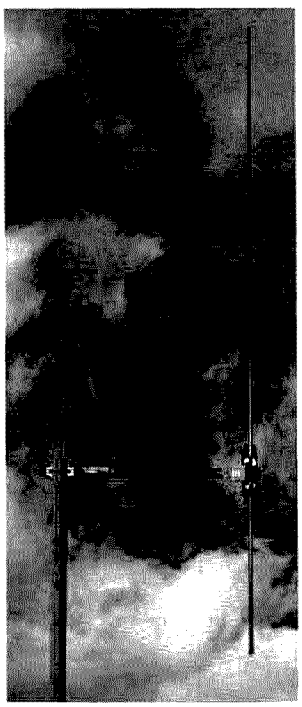
In the 3-Watt position, the swr appeared to be lower than 50 Ohms, probably around 25 Ohms. Here, your signal goes directly to the driver stage, and don't use anything more than an HT here! You could damage the driver if you hit it with 10 Watts of power. Again, use caution in selecting the desired drive range.

When was the last time you saw an amplifier that put out 200 Watts for 2.5 Watts of drive? Or, for that matter, 100 Watts output for 1/2 Watt of drive? (This amplifier ought to make happy those types who insist on using handie-talkies as mobile rigs.) We did not measure linearity, although on-air reports have been good. At no time was I able to get more than 200 Watts out of the amplifier, and at that output level the voltmeter still indicated 14 volts. MM rates the current consumption in this mode at 30 Amperes, so the RS-35 can do the job nicely.



In this particular model, the rf VOX keying didn't work at all. I'm not sure what caused this problem, but the unit I obtained was one of the early production models, so I must assume component failure. One other area of complaint is the method used to connect the front panel to the internal circuit board: The panel uses a 7-pin inline socket, much like half an IC socket, while the circuit board has a mating plug.

Unfortunately, there is no way to see if these two parts mate when attaching the front panel, so I spent nearly a half-hour after making the receiver tests trying to get the panel back on and make contact. Conversations with the US importer indicate that this method of connection has been changed to a flexible ribbon cable. At least the folks at MM are responsive to complaints!

This is indeed a clever amplifier, and one which any 144-MHz operator would love to have in his or her station. The advantage of being able to custom-tailor your input-drive requirements make it only that much more desirable, and it takes care of the need for a high-power amplifier for SSB/CW and FM simplex work. I'd venture to guess that it would also work nicely in repeater service, derated to the 100-Watt level with a small cooling fan. That is indeed an enormous heat sink!

Price class: $400. US importer: *The PX Shack, 52 Stonewyck Drive, Belle Mead NJ 08502.*

NEW PRODUCTS

The Omni antenna.

AN IMPROVED OMNI FROM GROVE

The Omni, developed by Bob Grove and now improved, is a non-directional vertical dipole with continuous 30–960 MHz coverage. A single 66-inch element works on the harmonic principle to provide in- and out-of-band scanner reception throughout the VHF/UHF spectrum.

Low band, high band, UHF, military and civilian aircraft bands, and cellular radio telephone, all can be received on this one antenna. All mounting hardware is included. Requires a TV type-F connector on your coax.

For further information, contact *Grove Enterprises, Inc., PO Box 98, Brasstown NC 28902; (800)-438-8155.*

NEW SLIMLINE OHMMETER BY NES

The new addition to the Slimline series of digital panel meters allows reading resistances never before possible. With the high resolution, stability, and accuracy of this latest product, you can determine if just one turn of a winding (motors, transformers) is shorted. The contact resistance of a switch, relay, or connector, can easily be measured.

The Slimline ohmmeter uses high-stability, amplifier circuits to permit better accuracy and stability than most laboratory units. These integrated circuits and techniques are the same ones used in the past in medical electronic-monitoring equipment. The ohmmeter is capable of the 4-wire- or 2-wire-measurement technique. With the 4-wire approach the extra two wires allow automatic compensation of all wire, connector, and switch resistances in the measurement path. The 2-wire approach allows manual zeroing of the path's resistance. There are many proponents of each; both have their advantages.

As with all Slimlines, the meter mounts on the front of the panel only. The meter measures 3½ x 4½ x ¾" and can be adapted easily for programmable controller or computer interface. Parallel or strobed BCD, serial ASCII, RS232, or RS422 are all available. This allows an easy way to grow into an automation test or CAM system.

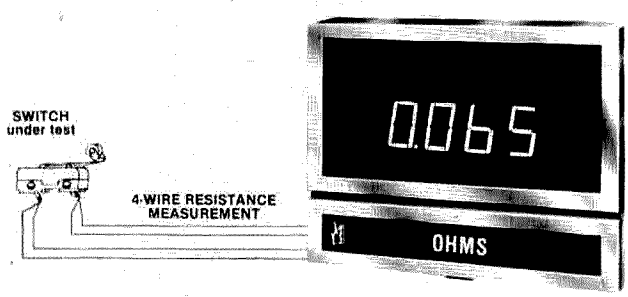
As with all NES meters, the Slimline ohmmeter is backed by a full 3-year unlimited warranty.

For more information or application assistance, call or write: *NES, Inc., 3003 Wakefield Drive, Carpentersville IL 60110; (312)-426-5900.*

UNCLE BILL'S SOFTWARE CODES AND ANTENNAS

Uncle Bill's Code Course is a Morse code training program designed for the Commodore C-64 and C-128 computers. The Code Course is very user friendly. The program is broken into three parts, allowing instruction at any level from beginner to professional.

Part 1 introduces each character by calling for the student to press a key, then hear the properly sent Morse code equivalent and view the character on the screen. The sight and sound combination is used for emphasized (dual sensory) learning.



Part 2 sends a properly formed Morse character and requires the student to respond by pressing the appropriate key. If an incorrect response is made, the character will be resent. This will continue until the proper response is made, or a special key is pressed to assist the student. At the end of each session in this part, the computer will grade the student's progress.

Part 3 sends properly formed Morse characters in random groups of five characters each. The sending speed is selectable from 5 GPM to 20 GPM. This part gives the student practice at writing down what he hears. The student's written responses may later be checked for accuracy by viewing the screen. The computer will send these groups until told otherwise, not just one group at a time.

Random code groups were selected, as they are the most difficult to "copy." Mastering of this section will enable the passing of any code test given, including the commercial Radio Telegraph Operators test.

All Morse is sent at 20 WPM. Hence, the student has only to learn character sounds once. This method is sometimes referred to as the Farnsworth method. Varied sending speeds in Part 3 are attained by adjustable spacing between the characters.

Operating instructions are in-

The NES Slimline ohmmeter.

cluded as a part of the program, and are carried on the screen.

Antenna System

Uncle Bill's "Antenna System" is an antenna modeling and design package usable for planning HF antennas of most types. It is very user friendly and has helpful graphics. The program is broken into two parts.

Part 1: Designs standard (full size) antennas of horizontal, vertical and yagi types. Merely enter the frequency you wish to design an antenna for, and the screen will fill with all the necessary dimensions for proper planning. Ask the computer for a display, and a model of your selection will be shown graphically, complete with dimensional labels.

Part 2: Designs dipole antennas of reduced size for the ham who does not have the necessary lot size for full-sized HF antennas. The operator has only to enter the frequency of planned operation and answer a few questions about his own circumstances (all menu driven). Based upon the responses, a computer model of a custom designed antenna will be displayed. All dimensions are given with the graphics model. The "Antenna System" is particularly useful for designing 80- and 160-meter antennas.

Operating instructions are included as a part of the program, and are carried on the screen.

For further information, contact: *Uncle Bill's Fine Software, PO Box 2403, Falls Church VA 22042.*

THE LISTENER'S HANDBOOK FROM GROVE

Two of the most popular Grove books were Bob Grove's *Communications Monitoring* and *Behind The Dial*, now out of print.

The basic subject material has been taken from those two books, extensively reorganized, updated, and supplemented, with new illustrations and photos. The result is *The Listener's Handbook*, by Bob Grove.

Virtually every topic of interest is explained in Bob's easy-to-understand manner. Subjects include the radio spectrum and its users; security and surveillance equipment and techniques, including scrambling; how to choose a receiver; selecting the best antenna for your installation; all about coax cable, preamplifiers and preselectors; interference and its cures, and other topics.

For the do-it-yourselfer, Bob has included a special home projects section with easy-to-build filters, tuners, receivers, descramblers, *antennas*, power supplies, converters, amplifiers, and other essential accessories for the serious listening hobbyist.

Containing 94 pages (softbound, 8-1/2 x 11) and more than 100 illustrations, charts, and tables, *The Listener's Handbook* is a reference for any listener to the first 1,000 megahertz of the radio spectrum.

For further information, contact *Grove Enterprises, Inc., PO Box 98, Brasstown NC 28902.*

Yaesu's YS-60 meter.

Yaesu's YS-500 meter.

MONITORING TIMES GROWS TO 40 PAGES

Monitoring Times, the comprehensive and timely tabloid on monitoring the total radio spectrum, has now grown to 40 pages at no additional increase in subscription cost.

MT covers VLF to microwave, BBC to satellites, law enforcement radio to private broadcasters, aircraft to ships at sea, for complete listening coverage. Free sample available upon request to the publisher, *Grove Enterprises, Inc., PO Box 98, Brasstown NC 28902.*

RF NOTES #2

RF Notes No. 2 is the second in the series of rf design-aid programs for problems frequently experienced in radio frequency design. RF Notes No. 2 contains four programs and can aid in such activities as "Inductor Design." Single-layer coils, both close- and space-wound, and Toroid coil design. "Complex Impudence Matching Circuit Design includes L, PI, T, and wideband configurations. "Attenuator Pads," designs 11 different pad configurations. Additionally, a short program, "Capacitor Application Evaluation," is included. Color or monochrome, *for IBM* 128K, graphics card required. For more information, call or write Etron RF Enterprises, PO box 4042, Diamond Bar CA 91766; (714) 594-8471.

YAESU HAS TWO NEW IN-LINE METERS

Yaesu Electronic Corporation announces two new in-line swr and power meters. The YS-60 measures both average and peak power output, reflected power, and vswr in the range from 1.6 to 60 MHz. The YS-500 performs *the* same measurements covering the 140-to-525-MHz range. Three functions provide monitoring of either forward or reflected average transmitter output power for CW, AM, FM and FSK modes, and vswr for testing the performance of antennas. The linear circuit design assures accurate measurements with minimum insertion loss over the entire specified frequency range, even at low power levels.

For further information, contact any Yaesu dealer or Yaesu Electronics Corporation, PO Box 49, Paramount CA 90723.

NEVER SAY DIE

from page 4

So, what have you found to work best in spreading HI? Has anyone found demos in *shopping* malls to do anything? Most of the ones I've seen have kept the public so far away that they couldn't see, hear, or understand what was going on. There's a self-destructive drive to show off esoterica such as slow-scan or RTTY at fairs and malls. These are just ego-gratification exercises. If we want to get HI around we may do better to stick to simple things like voice communications and rag-chewing. What've you found?

To change metaphors, I think you *may* find that it's important both to expose and re-expose the potentially infected to the virus. It's sort of like getting them to take the bait, then setting the hook.

In my case, Fred had me baited, but the hook didn't really set until about five years later when someone gave me a box of radio parts. There were enough for me to build a radio circuit out of Popular Mechanics. The hook was set—permanently. So let's hear it on how you got caught up in amateur radio. Did you go for the bait and get hooked like I did? We can learn how to spread our joy to others if we share our experiences.

Yes, I know, you've probably never written to an editor before. Well, that sort of irresponsibility doesn't wash with *73*. When you send in your subscription you're just getting started here. I expect you to join me and the others to get some recognition for the hobby, to get more hams, and to help get us back to where every major communication development has been invented and pioneered by hams, the way it used to be before 1963.

Did a ham magazine have much to do with your getting licensed? If so, try to remember what it was that did it to you. Let me know so I can do it some more. I can make *73* any way I want it, and what I want is to make it so it's got what you want to read and will help amateur radio to grow. Let me hear from you.

WHILE YOU'RE WRITING

One thing that is never far from my mind is getting a *new piece of* ham gear. So, like you, I read over the ads carefully. Since the smaller the type, the better the bargain, I tend to get out my magnifying glass and go over the dealer ads with particular care. But I find myself getting confused. Oh, I know most of the model numbers, but not all. And I remember some of the recommendations I've gotten over the air, but I'm not so sure about some of the gear I'm interested in buying.

What I'd like to see is a regular listing—maybe quarterly—of what you think of all that ham gear you've bought. If you'd just go through your ham shack, list the gear you're using and let me know how you like it—say, on a scale from zero to nine—I'll tote up the votes and run them in *73*, listing the make, model, number of votes, and average score. Sure, I expect a manufacturer will send in a nine for his equipment, and his competitor will send in a zero. But by the time we have a few hundred votes, we'll have a very good idea *of where* truth lies.

Another thing. I enjoy reading the reviews of new products as much as you do. But I'd much rather know the opinions of a dozen or so active hams who bought the unit, after using it for a few weeks, than the opinion of some joker who is writing to make money and who doesn't want to make the manufacturer mad by being too critical. I want to know what the average ham thinks of the product—what you think of it. So, the next time you buy a new piece of gear—an antenna, a rig, an HT, test equipment, or anything else—once you've used it for a while and know its good and bad points, how about dropping me a letter and telling me what you've found? If I print it I might just extend your subscription a month or two—maybe a year, if I find your opinions particularly interesting. Mostly you'll be doing it either to help other hams avoid a bad experience or to help a manufacturer who has brought out something worth knowing about. Here's a chance to talk about ease of use, instructions, damned-fool dials, weird connectors, good signal reports, and so on. We're supposed to be communicators, so let's communicate!

Most of us will be particularly interested in what you think of the products which are currently being advertised in the ham magazines. But I think we also will be interested in older products, *ones* we see at flea markets and ham auctions, so don't figure it's too late once something has been out for a year or so. Heck, I'm still seeing Gonset Communicators selling at Dayton!

Once I'm able to get your Home Test Report into *73*, I'd like to set up a place on the reader-service *card for everyone* to vote for the most helpful report of the month, with perhaps a $100 reward for the winner. I believe that good actions should be rewarded.

Send your reports to Home Test Reports, *73* Magazine, WGE Center, Peterborough NH 03458. And, yes, I want to hear from hams anywhere in the world.

AND ANOTHER THING. . .

The word is that a few of you have been busy doing more than just rag-chewing. I don't put much stock in these reports, but just in case you have been playing around with some crazy things like slow-scan, RTTY, satellites, moonbounce, or such, know that I want to hear more about what you're doing and, if you know, why you're doing it.

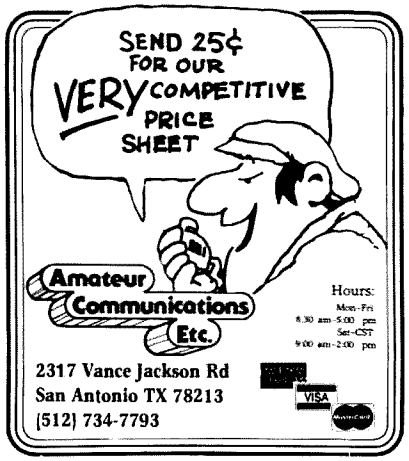
It's been years since I used RTTY, so I hardly know where to start today. What do you recommend I buy? Do you have to build anything? Who's on the air for me to talk with? How about contests? How many get involved and what does it take to win? How many countries can I hope to work on RTTY these days? How many standards are there? Do I use the old five-bit code, ASCII, or what? My old 1948 RTTY gear should probably be in a ham museum now.

Is there any reason for me to get going on slow-scan again? I tried that *around* 15 years ago *and* had a ball. But then, like most everyone else, I got bored with the lack of program material from others—and lazy in making my own. I remember a chap getting DXCC on slow-scan—how many countries might I work today if I had a good station? Are any DXpeditions dragging along slow-scan equipment? I remember making SSTV contacts when I operated from KC4DX on Navassa back in 1972, and also from Amman as JY8AA, and also from JY1 in 1973.

What's my best bet in gear to work through OSCAR these days? My old 432/145-MHz 1975 setup is long gone. My best DX was Moscow, where I had a 20-second window one day. That took some doing—and luck. But what should I get now to get on with a good signal? If you're working the satellite with some success, let me know what I need in a rig, a receiver, and antennas.

One of my great enthusiasms around 15 years ago was cross-band repeater operation. I had WR1AAB set up on our nearby Pack Monadnock mountain, with cross links to six and ten meters. With that, the local two-meter gang was able to make lots of contacts all around South America. I had another repeater setup at home linked to twenty meters. The FCC scotched that for a few years, but now it's blooming again and I'd like to know what you're doing along this line. Who knows, I might be in your neighborhood and want to see what I can work. I get around a lot—a whole lot.

So if you're having fun with some special ham interest, tell me



Hmmm, that paunchy chap on the left has been dipping into too many dim sum. That's me with Tim Chen BV2B in the middle and Ken Miller K6IR on the right. Ken and I have been visiting Tim every October for a while while on a round of Asian consumer electronics shows. As a matter of fact a surprising number of hams are on the trip with us—which makes it all the more fun. Maybe you worked Tim or his recent visitor, Barry Goldwater, during their January stint.

and the other 73 readers what you're doing, why it's fun, and how we can join in the fun. What can we build? What can we buy? What short cuts are there to save some money or time? How about some references to good information sources?

GOOD HELP

If I'm going to get *73* back into shape, I'm going to need a lot of help. I know some things to do and you'll tell me more, but I'm looking for someone for my staff who can make my W2NSD/1 ham station really sing. I want to work with someone to help me get active on OSCAR again, to get on RTTY again, and to see what I can do with packet radio. If you know of someone with some experience in some of these things and who would like more than anything else to make hamming a life's work, someone with some technical smarts—any age, any sex, any race, any religion—pass the word!

Look out *Ham Radio*! Look out *CQ*! *73* is going to do those things which should be done so you won't want to miss an issue—and maybe we can get amateur radio itself moving again. We have the greatest hobby in the world, and that's not just puffery. Our hobby is the key to getting our country back into the act in consumer electronics, so you and I have a responsibility. We've got to make amateur radio and the fun it provides known. I need your help to do this. If we can work together, nothing can stop us!

COMPUTER PROGRAMS AID IN RADIO FREQUENCY DESIGN

For the IBM PC, PCXT, and PCjr Computers, the RF Notes series of design aid programs can help in solving daily Engineering problems. Intended as inexpensive tools, these programs aid in circuit design as well as serve as an invaluable source of reference material.

RF Notes 1 can aid in Mixer Cross-Product evaluations, Resonant Circuit design, Filter design, Microstrip and stripline design and more.

RF Notes 2 will assist in Impedance Matching circuit design, Inductor design (including Toroids), Capacitor evaluation, and more.

RF Notes 1 is priced at $57.00, RF Notes 2 is $60.00, plus $3.00 each shipping & handling. For PC DOS 2.1, Graphics card required. Available in Color or Monochrome. Send Check or MO, or write to:

INTRODUCING SACCK
(for the C-64)
Semi-Automatic CW Contest Keyboard
(WITH INTERFACE)

SACCK is a POWERFUL semi-automatic CW keyboard with its own INTERFACE.

SACCK comes with many AUTOMATIC features that makes CW contesting and rag chewing both easy and fun.

A few of the many OUTSTANDING features are:
10 MESSAGE BUFFER • DUPE CHECKING WITH PROPER MESSAGE PLACED IN THE XMIT BUFFER AUTOMATICALLY • AUTOMATIC TEXT INSERTION • ON LINE CODE SPEED CHANGE • CHAR., WORD, LINE AND MESSAGE XMIT OPTIONS AND MUCH MUCH MORE!

CRUMTRONICS

Little Board™ $249
The World's Least Expensive CP/M Engine

CP/M 2.2
INCLUDED

- 4 MHz Z80A CPU, 64K RAM, Z80A CTC, 4-32K EPROM
- Mini/Micro Floppy Controller (1-4 Drives, Single/Double Density, 1-2 sided 40/80 track)
- 2 RS232C Serial Ports (75-9600 baud & 75-38, 400 baud), 1 Centronics Printer Port
- Power Requirement: +5VDC at .75A; +12VDC at .05A / On board -12V converter
- Only 5.75 x 7.75 inches, mounts directly to a 5-1/4" disk drive
- Comprehensive Software Included:
  - Enhanced CP/M 2.2 operating system with ZCPR3
  - Read/write/format dozens of floppy formats (IBM PC-DOS, KAYPRO, OSBORNE, MORROW...)
  - Menu-based system customization
  - Operator-friendly MENU shell
- OPTIONS:
  - Source Code
  - TurboDOS
  - ZRDOS
  - Hard disk expansion to 60 megabytes
  - SCSI/PLUS™ multi-master I/O expansion bus
  - Local Area Network
  - STD Bus Adapter

Atco NJ 08004

DX CONTEST—PHONE ARRL INTERNATIONAL
Starts: 0000 UTC March 1
Ends: 2400 UTC March 2

This annual DX contest for all DX hunters is sponsored by the **ARRL** and open to all amateurs worldwide. W/VE amateurs are to work as many amateur stations in as many **DXCC** countries as possible on **1.8** to **30 MHz**, excluding the 10-MHz band. Foreign amateurs are to work as many W/VE stations in as many states and provinces as possible. Check *QST* for any last-minute rule changes. Operating categories include:

(A) Single Operator—one person performs all operating and logging functions. Spotter nets are not allowed and only one transmitted signal may be used at any given time. Within the single-operator category, participants may compete within all band or single-band categories as well. Single-band entrants who make contacts on other bands should submit logs for checking purposes.

(B) Multi-Operator—more than one person operates, checks for duplicates, logs, etc. Within this category, entrants may compete within single-transmitter, two-transmitter, or unlimited-transmitter categories. Single transmitter implies only one transmitted signal at any given time and once station has begun operation on a given band, it must remain on that band for at least 10 minutes. Listening time counts as operating time. Multi-op single-transmitter stations must keep a single, chronological log for the entire contest period.

Two-transmitter multi-op entrants are limited to only two transmitted signals at any given time. Again, each station must stay on a given band for a minimum of 10 minutes. Both transmitters may work any and all stations; the second transmitter is not limited to only working new multipliers. Each of the transmitters must keep a separate log.

With an unlimited number of transmitters for multi-op entrants, only one transmitted signal per band is permitted at any given time. Separate, chronological logs must be kept for each band.

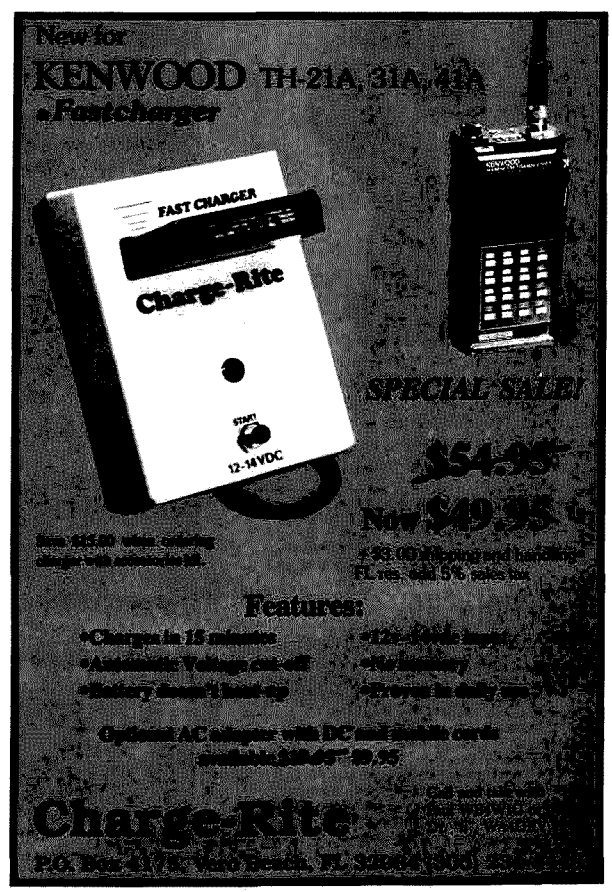
(C) **QRP**—10 Watts input or less (or 5 Watts output or less), single operator, allband only.

Operators must observe the limitations of their operator licenses at all times. Your callsign must indicate your DXCC country station location. One operator may not use more than one callsign from any given location during the contest period. The same station may be worked only once per band; no crossmode, crossband, or repeater contacts. Aeronautical- and maritime-mobile stations outside the US and Canada may not be worked for QSO or multiplier credit by W/VE stations. All transmitters and receivers must be located within a 500-meter-diameter circle, excluding directly-connected antennas. This prohibits the use of remote receiving installations. However, multi-operator stations may use spotting nets for multiplier hunting only.

EXCHANGE:

W/VE stations send **RS** and state or province. **DX** stations send **RS** and power as three-digit number approximating transmitted input power.

SCORING:



All stations count **3** points per valid QSO. W/VE multiply QSO points by sum of DXCC countries (except US and Canada) worked per band. **DX** stations multiply QSO points by number of US states (except KH6/KL7) and District of Columbia (DC), VE1–7, VO, and VE8/VY1 worked per band (58 maximum per band).

AWARDS:

Plaques awarded to top W/VE scorer in each entry category; top scorer in the single-operator all-band category worldwide and on each continent; worldwide leaders in the single-operator single-band, QRP, multi-op single-transmitter, multi-op two-transmitter, and multi-op unlimited categories—plus additional special plaques as sponsored. Certificates will be awarded to top single-operator, allband entries from each country and **ARRL** section; top single-band entries in each US call area and each country; top multi-op entries in each country, US call area, and in Canada. Additional single-band and multi-op certificates will be awarded if significant effort or competition is displayed. Also, DX entrants making more than **500** QSOs on either mode will receive certificates. **ARRL** affiliated clubs also compete for gavels on three levels: un-

CALENDAR

Mar 1–2	ARRL International DX Contest—phone
Mar 8–10	Virginia State QSO Party
Mar 15–16	YL-ISSB QSO Party—CW
Mar 15–16	Bermuda Amateur Radio Contest
Mar 29–30	Rio CW DX Party
Apr 12–13	CARF Commonwealth Phone Contest
Apr 14	ARRL 144-MHz Sprint
Apr 22	ARRL 220-MHz Sprint
Apr 30	ARRL 432-MHz Sprint
May 8	ARRL 1296-MHz Sprint
May 17	ARRL 50-MHz Sprint
May 31–Jun 1	National 6-Meter Invit. Net Activity Day Contest
Jun 7–8	ARRL VHF QSO Party
Jun 28–29	ARRL Field Day
Jul 1	CARF Canada Day Contest
Jul 12–13	IARU Radiosport Championship
Aug 2–3	ARRL UHF Contest
Aug 16–17	New Jersey QSO Party
Sep 13–14	ARRL VHF QSO Party
Oct 11–12	Rio CW DX Party
Nov 1–2	ARRL Sweepstakes—CW
Nov 15–16	ARRL Sweepstakes—phone
Dec 5–7	ARRL 160-Meter Contest
Dec 13–14	ARRL 10-Meter Contest

limited, medium, and local clubs.

ENTRIES:

All entrants are encouraged to use official forms available from ARRL headquarters to report contest results. Logs must indicate times in UTC, bands, calls, and complete exchanges. Multipliers should be clearly marked in the log the first time worked. Entries with more than 500 total QSOs must include cross-check sheets (dupe sheets). All operators of multi-op stations must be listed.

Entries must be postmarked within 30 days of the last contest weekend, otherwise they will be classified as check logs—no extensions, no exceptions. All stations are requested to send their entries in as early as possible. Each entrant agrees to be bound by the provisions of the ARRL rules, licensing authority, etc. The decisions of the ARRL Awards Committee are final. Usual ARRL disqualification rules apply. Address entries and forms requests to ARRL Headquarters, 225 Main St., Newington CT 06111.

VIRGINIA QSO PARTY
Starts: 1800 UTC March 8
Ends: 0200 UTC March 10

The 1986 QSO party is again sponsored by the Sterling Park Amateur Radio Club of Sterling Park VA. The same station may be worked on each band, once on each mode. VA stations may contact in-state stations for QSO and multiplier credit. VA mobile stations must sign as mobile and may be worked in each new county they operate from for new QSO and multiplier credit regardless if previously worked on the same band and mode in another county. Stations on county-line borders count for only one QSO regardless of the number of multipliers they offer. QRP stations must run 5 Watts or less for their entire operating time.

EXCHANGE:

QSO number starting with 001 and QTH consisting of state, province, DX country, or VA county. VA stations note that the reference for valid counties is the *CQ's Counties Award Record Book*, which lists a total of 95 counties.

FREQUENCIES:

Phone—3.930, 7.230, 14.285, 21.375, 28.575, and anywhere on 160-meter band except in DX windows. CW—60 kHz up from the low end of each HF band and anywhere in 160-meter band or Novice subbands.

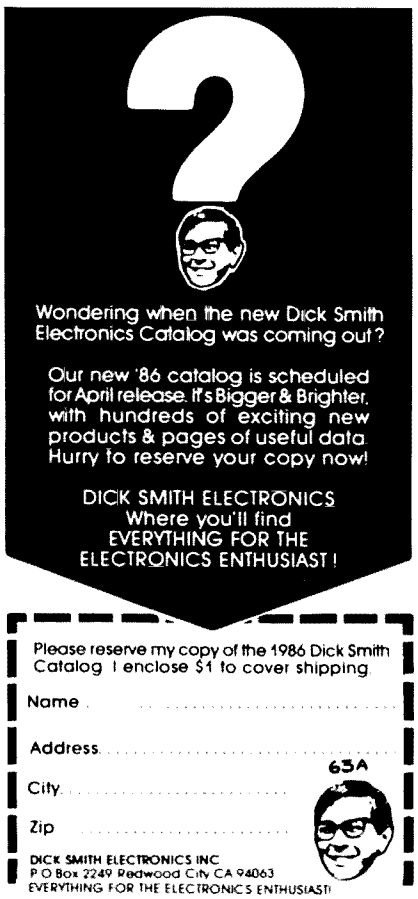
SCORING:

Count one point per voice QSO; two points per non-voice QSO (RTTY, CW, SSTV). No cross-mode QSOs. VA stations multiply total QSOs by the sum of states, Canadian provinces, DX countries, and VA counties worked. Others multiply QSOs by the number of VA counties worked. VA mobiles may count fixed stations only once as multipliers. VA stations vying for the CW-only award will have only CW contacts and multipliers counted.

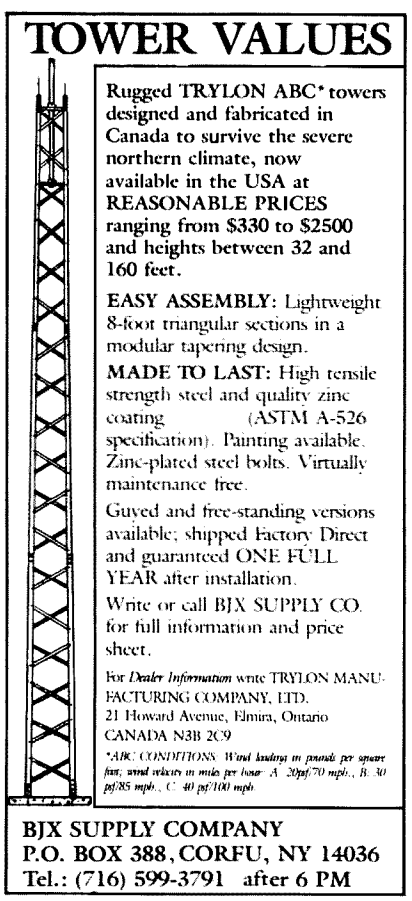
AWARDS:

Engraved plaques to the top-scoring stations in the following categories: High VA single operator (fixed location, multimode); high VA CW-only station; high VA mobile; high out-of-state (including DX) station; high VA QRP station; high 4th call area club award; and high out-of-state station. Certificates awarded to winners of VA counties, states, Canadian provinces, and DX countries.

ENTRIES:



Follow ARRL standard contest guidelines for logs. Indicate each new multiplier as worked and include a summary sheet with your log. Indicate on summary sheet if mobile, QRP, or if entering for CW-only award. Put your name, callsign, complete address, and name of your radio club (if vying for the club award) on the entry forms. Mailing deadline is April 1, 1986, and should be addressed to: Virginia QSO Party, c/o Barry Pybas KW4I, 313 W. Derby Ave., Sterling Park VA 22170.



WISCONSIN QSO PARTY
Starts: 1800 UTC March 9
Ends: 0100 UTC March 10

Use both CW and phone; stations may be worked once per mode on each band. Mobiles may be worked once per mode per county that they operate from. No repeater QSOs allowed! Entry classifications include: single operator, single transmitter; multi-operator, single transmitter; multi-operator, multi-transmitter; single operator, Novice/Technician.

EXCHANGE:

RS(T) and state, province, or WI county.

FREQUENCIES:

Phone—3.890, 7.290. 14.290; CW—3.550, 3.275, 7.050, 7.125, 14.050, 21.150.

SCORING:

Phone contacts count 1 QSO point; CW contacts count 2 QSO points, Wisconsin stations multiply QSO points by total number of states, provinces (13 max.), and WI counties. DX countries count for QSO points but not multipliers. Non-WI stations multiply QSO points by number of Wisconsin counties (72 max.). As a bonus, WI mobiles/portables add 500 bonus points for each county that you operate form outside your home county with a minimum of 15 QSOs per county to qualify.

AWARDS:

Awards will be presented to the highest single-operator scores in each state and province. Wisconsin awards to 10 highest single-operator entries plus highest multi-operator single- and multi-transmitter entries, highest Novice/Technician, and highest aggregate club score. Club member stations must be located within 50 miles of the club except for mobiles.

ENTRIES:

All entries must contain a log consisting of: time in UTC, call, RS(T), state, WI county, mode, and a score summary. Summary must include your name, address, and callsign. Circle new multipliers as worked. Logs containing more than 100 QSOs must be accompanied by a dupe sheet (use a separate dupe sheet for each mode). Mobile entries must indicate county changes in log and submit a separate dupe sheet for each county. Entries must be postmarked by April 15 and sent to: Wisconsin QSO Party, c/o West Allis Radio Amateur Club, PO Box 1072, Milwaukee WI 53201.

BERMUDA AMATEUR RADIO CONTEST
Starts: 0001 UTC March 15
Ends: 2400 UTC March 16

This is the 28th year, again sponsored by the Radio Society of Bermuda. The contest is open to all licensed amateurs in Canada, USA, United Kingdom, and the Federal Republic of Germany. Of the 48-hour contest period, your total operating time cannot exceed 36 hours, with off periods clearly logged. Each off period must not be less than three consecutive hours. All stations must be single operator only and must be operating from their own private residence or property. All use bands, 80 through 10 meters. No crossband or crossmode contacts are permitted.

EXCHANGE:

All stations will send RS(T) reports and give the following: Canadians add province, UK stations add county, US stations add state, West German stations add DOK#, Bermuda stations add parish. US and Canadian stations may exchange reports with West German, UK, and Bermuda stations only. UK and West German stations may exchange reports with US, Canadian, and Bermuda stations only. Bermuda stations may work stations in the UK, US, West Germany, and Canada only.

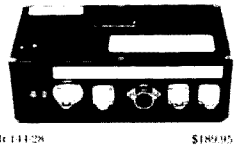
SCORING:

Each completed contact, on each band, counts 5 points. A phone and a CW contact with the same station on the same band will count if they are made at least 30 minutes apart. For all stations outside Bermuda, the multiplier is the total number of Bermuda stations worked on each band. For Bermuda stations, the multiplier is the total number of states, provinces, countries, and DOK# worked on each band. A multiplier may be counted only once per band.

AWARDS:

Printed awards to the top scorer in each state, province, country, and DOK area. The top scorer in Canada, US, UK, and West Germany shall receive a trophy to be awarded at the Society's Annual dinner held in October of each year. Round trip air transportation plus accommodation will be provided to overseas winners to enable them to receive their awards.

ENTRIES:



Logs must show all dates and times in UTC. A separate sheet must be used for each band. All contestants should compute their own scores and check for duplicate contacts. Dupe sheets must be submitted with logs to cover each band where more than 200 contacts are logged. For every duplicate contact for which points are claimed, a penalty or three contacts will be deducted by the contest committee. An excess of claimed duplicates may mean dis-

qualification. No penalty will be exacted against duplicates for which no points are claimed. Each page must be clearly numbered and marked with contestant's call, year, and band to which it refers. All contestants must sign a statement that they have complied with the rules and terms of their license. All logs must be received by the Contest Committee, Radio Society of Bermuda, Box HM275, Hamilton 5, Bermuda, not later than May 31. Overseas contestants are recommended to forward their logs via air mail. All decisions of the contest committee are final. Bermuda Parish abbreviations are as follows:

SAN—Sandys
PEM—Pembroke
SOU—Southampton
HAM—Hamilton
STG—St. George
DEV—Devonshire
WAR—Warwick
SMI—Smiths
PAG—Paget

YL ISSB QSO PARTY—CW
Starts: 0001 UTC March 15
Ends: 2359 UTC March 16

The contest is open to all amateurs but the emphasis is on member participation and member-to-member contacts. Operating categories include: single operator, DX/WK partners, and YL/OM teams. All bands will be used. VHF and UHF may be used, but all contacts must be direct and not through repeaters. Nets are not allowed!

EXCHANGE:

RST signal report. State, province or county, name; ISSB number (if member), and DX/WK partner's call.

FREQUENCIES:

On HF use the USA General-class band portions. Check 80 and 40 meters on the hour.

SCORING:

Score 3 points for each member contacted on own continent, 6 points if different continent. Non-members contacts count one point regardless of location. Only member station contacts count for multipliers. Multipliers are each US, VK, ZL, and VE state or province, plus each DX county. When DX/WK partners contact each other, it counts as a double multiplier. If your total input is 250 Watts or less during the entire QSO party, then count an additional power multiplier of two. Final score is sum of QSO points times the total multiplier.

AWARDS:

Special certificates will be awarded to the winners of each category. Regular certificates for country, US state, and Canadian province winners.

ENTRIES:

Logs must show date/time (UTC), station QSOed, RST, mode, band, SSBer number, state/province/country, and period of rest time. Summary sheets show states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. Send logs and summary sheets to Bill Early WA9AWA, PO Box 401, McHenry IL 60050-0401, prior to April 30. Be sure to indicate who your DX/WK partner is!

RIO CW DX PARTY
Starts: 1500 UTC March 29
Ends: 1500 UTC March 30

Sponsored by the Pica-Pau Carioca (Rio Woodpeckers CW Group), PO Box 2673, 20001 Rio de Janeiro, RJ, Brazil—with the cooperation of all other Brazilian CW groups. The purpose is to promote 2-way CW contacts between Brazilian and DX stations, enabling DX stations to obtain QSLs valid for several Brazilian Awards. The event is held twice each year on the last full weekend in March and the second full weekend in October.

The general call is "CO RIO DX PTY." Use all HF amateur bands within your own station license authority. Exchange RST, name, and QTH. There are no logs, but quick QSLing (via bureau or direct) is essential.

Reference frequencies are as follows: 3.510/3.520, 7.020/7.030, 14.030/14.050, 21.030/21.050, 21.130/21.150, 28.030/28.050.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

You know, sometimes it occurs to me that month after month I have been asking you for input on what you all consider important RTTY topics. I get quite a kick out of your letters and try to answer every one of them. What I have failed to do, however, is let the rest of you in on what your vocal (prolific) buddies have been saying.

One of you, who shall remain nameless for reasons that will become obvious, writes that he has "obtained" a copy of Clay Abrams' RTTY program, detailed here last month, and wonders where he might obtain instructions for the program. Well, if you did not receive instructions with the copy you obtained, I will assume you obtained a "bootleg" copy, that is, one made for you by a buddy, and not bought from Clay. You see, that's the problem. The number of copies circulating is so many more than the number of copies sold that Clay decided that staying in the CoCo software line was more an act of charity than business, so he left.

If you or anyone else who wants full data on the Abrams program has a sudden attack of conscience, you might drop Clay a note at Clay Abrams Software, 1758 Comstock Lane, San Jose CA 95124. Explain your situation to him and see what he says. Of course, I am sure he would be happy to hear from those of you who do not yet own a copy of the program, and who would like to buy a copy.

Congrats to Patrick Spinler KA0UBM, a new Novice licensee out in Blooming Prairie MN. Patrick is an Apple buff who would like to take a shot at writing a RTTY program for the Apple that would have all the features a ham would want. Patrick wants to know what features we would like to see in an "ideal" program. Well, folks, shall we inundate him? No, seriously, Patrick, read along with this column over the last few, and coming, months, and I think you will get the ideas you are looking for. And when you get it together, let me know, so we can share it with the multitudes, okay?

Dave Machlitt, a consulting entomologist (I wonder if he is good at debugging programs) in Ventura CA passes along the newsletter of his local computer club. With quite a bit ofinterest in both the CoCo and C-64 computers evident, it looks like activity with these "low-end" machines continues unabated. Thanks for the information, Dave.

Speaking of C-64s, Richard W. Keusink K7VPL lets us know that several of the items he has bought after reading about them here in "RTTY Loop" have turned out quite well, particularly some of the AEA gear. He has some specific questions, however, which I cannot find answers to, so I will throw them out to you. He asks, "On bringing up the AEA CP-1 program, must I boot it up every time to get the separate QSO buffer; one of the nine message buffers? Can't I bring them all up at the same time? What good is my 1541 (disk drive)? Maybe I'm not storing the material correctly? I also can't load a message port to put in a guy's call without leaving the TR mode. Other hams do it. How do I do it? If I leave the TR mode, of course, I lose all the print. There must be some way to achieve this."

Well, gang, any answers? Drop them to me at the above address, and put "CP-1 Help" on the outside of the envelope so I'll be able to forward the material promptly.

Richard is also interested in locating press wireless signals, such as AP or UPI, on the HF bands. One of the problems you will have in finding press signals for domestic consumption is the relocation of many of these signals to non-HF modes of transmission. International signals should be readable, however, and with that window on the Pacific you have from up there in the Northwest, you should have pretty good luck. Check any of the books mentioned here over the last few months for some likely frequencies, Richard.

Regards to J.R. Mongrain, of Orange MA who is a TI-99/4A user. I hope that the material presented here a few months back regarding RTTY programs for the TI was of use to use to you, and I am happy to send along the material you requested.

Thanks for the kind words from Pam KB6DKZ in Saratoga CA. I

Crystal FSK Circuit

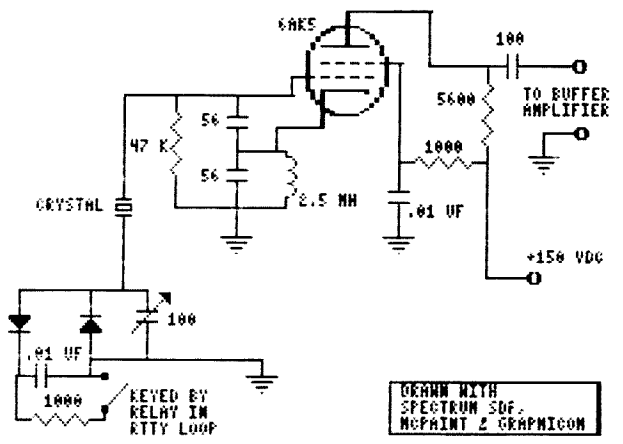

Fig. 1.

glad you find this column as useful as I hope it is, and will continue to try to answer all your questions.

Glenn Farnsworth K2EHM—Howdy Do! As another Apple user, I hope you have not been discouraged in your attempts to get onto RTTY. Again, I hope the material I sent along will provide some aid, and I hope to see you on the air real soon.

Let's see who else I can find in the file. Tom Dillon WJ6M of Los Gatos CA—thanks for the comments and I hope you are doing well on RTTY. Jim Conrad from Odessa TX—my best to you as well. Hope your VIC is RTTYing by this time. If he's not looking, I'll even pass along regards to fellow *73* Associate Editor Bill Gosney KE7C, who has been known to read this column now and then. Bill runs a mean award program, folks. When you finish this issue, why not flip to page 64 of the January, 1986, issue and take a look?

Commodore owners, listen up. I need your help. I have a letter here from Jeff A. Bordeaux which asks some questions I have not seen addressed before, and maybe one of you has the answer. He says that he has been told that, "amateur RTTY communications can be demodulated with a standard Bell type 103 modem used for telephones. Basically, you are supposed to program the RS-232 port on the Commodore-64 for 50-baud operation, five data bits, and modify prescaler values to receive at 45.45, 50, or practically any baud rate. A simple translater program derives ASCII characters off of the five-bit Baudot patterns.

"The method doesn't seem to work for me. Maybe the 200-Hz shift is too narrow for most of the RTTY signals here; maybe the receive frequency tolerance in my 1650 Automodem is too small, etc. I wonder if you may have had contact with someone who has tried this and succeeded.

"In any case, I would like to use a more versatile, but cheap method. I have heard that it is possible to demodulate practically any baud rate, shift, or bit pattern by simply strapping a diode to the Commodore user port and connecting it to the shortwave in some fashion. The method is supposed to use a high amount of software overhead (machine language), but I don't mind."

Well, Jeff, first off, I have problems using a Bell-type modem to receive RTTY, if only because of the tone pairs used. Whereas RTTY uses a 2125-Hz mark and either a 2295 Hz space (for 170-Hz shift) or 2975 Hz space (for 850-Hz shift), I will concede that these frequencies are not sacred, and that by judicious adjusting of the receiver bfo any two frequencies separated by 170 Hz (or 850 Hz) should be obtainable.

Contrast that with the standard tone pairs used on 300-baud modem (Bell type 103) circuits. For the usual operator, operating in the "originate" mode, transmit tones are at 1270-Hz mark and 1070-Hz space; receive tones are 2225-Hz mark and 2025-Hz space. Now, granted that the difference is 200 Hz, "only" 30 Hz away from the 170-Hz RTTY standard, but there is a bigger problem. The mark and space are reversed. This could be corrected

on HF by using the reverse sideband to receive, but transmitting would be a problem, as it would be offset from the receiver by a kHz or so.

Oh, well, I take it that these problems are not insurmountable, as according to your letter someone has done it. I will look forward to hearing from other C-64 owners as to their experiences with this scheme.

Paul Parker KF6OC of Tujunga CA has been trying to get the shift-pot circuit shown here some time back to work on RTTY with an old Globe Chief transmitter. Paul, there is one problem there. The shift-pot circuit is designed to shift a variable-frequency-oscillator circuit, not a crystal, such as you are using in the Globe. My experience, and I used a Globe Chief many years ago, is that shifting a crystal is difficult at best and cannot always be done. If you want to use the shift-pot circuit, you might do well to see if you can't pick up an older outboard vfo for the transmitter. There should be quite a few at the next hamfest you go to, often under $100 (or even less), which will do very well. And going by that old saw, if it's stable enough for SSB, it should be fine for RTTY.

Now, if shifting a crystal is the only way you have to go, you might try the circuit shown in Fig. 1. This vintage circuit will go well with the vintage transmitter you are using and is one way of shifting a crystal. In case you are curious, this circuit is at least twenty-five years old, as you can tell by the specified tube. At any rate, it might serve as a starting point for putting that Globe onto RTTY. Key the circuit through a set of cold contacts activated by your loop, either from the output of the terminal unit or with a reed relay in series with the loop. Layout is important, by the way. Try to keep the crystal and associated wiring as short and point-to-point as possible. Let me know how things go.

By the way, for those who follow such things, the diagram in Fig. 1 was drawn on my little old CoCo, using the Schematic Drafting Processor mentioned here a few months ago, available from Spectrum Projects. The diagram was then cleaned up with McPaint, a public-domain graphics program available in the download menu of the CompuServe CoCoSIG, and lettering put in with Graphicom, by Cheshire Cat, also available from Spectrum. Just shows to go you what a small system can do! Take that, Big Blue.

I have enjoyed chatting with many of you on CompuServe's HamNet. While packet radio is by far the leading topic expressed on the keys, many of you apparently are still interested in more "traditional" RTTY. The only problem is that the loudest group is the vanguard into new areas, while those of you still using Model 15s just go quietly along. Let me hear from all of you, by any means. I have been told that Murray RTTY is dead—do you think that is true? We heard that CW was dead, that AM was dead, that SSB was dead, and so on. It seems to be a popular pastime, declaring this or that phase of the hobby moribund. I don't know, maybe it's my profession, but I am not quite so willing to pull the plug. Are you?

As always, I welcome your comments, questions, barbs, and plaudits. Let me hear from you in the mail to the above address or on CompuServe EasyPlex, HamNet, or CoCoSIG. (Did you ever notice how they like to Double-Capitalize words?) That all important number is 75036,2501. In the mill for coming months will be columns on the Model 33 teletype SREGTR teleprinter, as well as a look at MacPrograms (sorry, couldn't help myself) that are available for MacRTTY (grin). More and more, you just never know what you are likely to find in "RTTY Loop."

Continuing our discussions from last month on transverters: Several readers have written regarding the low output from the transverter jack on ICOM series radios. Here are simple modifications that will yield about 10–15-dB increase in drive level at 28 MHz on both the ICOM 740- and 745-series radios. You'll need a Phillips screwdriver, soldering iron, wire strippers/cutters, and a short length of RG-174 coaxial cable.

First, remove the top and bottom covers on either radio. Then, locate the six screws that hold the back panel on, remove them, and gently slide the panel away so as not to pull out the nylon multi-pin connectors. Don't pull too hard or you might tear a wire loose from one of those connectors.

IC-740 owners first: On the back panel is a series of RCA-type phono jacks. One jack has nothing connected to it and is labeled SPARE. Locate the connection to the input of the FINAL board. This cable comes from J8 on the RF board and is marked TRF. Desolder this connection from the FINAL board. Now, desolder and tape off the cable to the XVRTR jack as you won't need it. Locate and resolder the cable from J8-TRF to the XVRTR jack, as this will now be your 28-MHz-drive source. Finally, prepare a short 3-inch jumper of RG-174 to be soldered from the SPARE jack to the input to the FINAL board. You'll also need to make up a short 2-inch RCA-male-to-RCA-male jumper with RG-174.

This completes the modification. You no longer need to tie pin 11 of J13 high with +8 volts to enable the transverter jack. However, you must reconfigure the radio for either transverter operation or conventional HF operation, by the way you connect the rear-panel RCA jacks. With a standard transverter, you need to make connections for 28-MHz i-f to the XVRTR and RCVR IN jacks. For regular HF operation, connect XVRTR to SPARE and RCVR IN to RCVR OUT. The bonus is that you will have more than enough drive to make full power with your particular transverter.

IC-745 owners next: Locate the cable from the RF board to the final amplifier. *Caution*: Don't get it confused with the cable from the filter board! Otherwise, you could wind up putting 90 Watts into your transverter input. Locate the rear-panel RCA-jack cluster. Unlike the IC-740, there is no SPARE jack available on the 745 (unless you want to drill a hole and mount one), so you'll have to make a big decision: Do you need the LOW BAND ANT jack? This connection comes into play when the dial is set below 1.5 MHz for a separate longwire antenna or whatever you would use on those frequencies. In the case of the two mods I performed locally, neither ham expressed any interest in this jack. If that is the case for you, then remove the coax from this jack and tape it off.

Next, remove the coax from the XVRTR jack and also tape it off. Locate the output from J10/TRF from the RF board, and reroute it to this jack and solder. Next, make up about 12 inches of RG-174 and run it from LOW BAND ANT jack back to the input of the FINAL board. Inspect your connections and make sure you haven't pulled any nylon connectors loose from the filter board. Replace the back panel and the covers. Finally, make up a short (2-inch) RCA-to-RCA plug jumper for the rear panel. The configuration is the same as for IC-740 users: 28-MHz i-f connections for your transverter go to XVRTR on transmit and RCVR IN on receive. For HF operation, jumper RCVR IN and RCVR OUT together as well as XVRTR and low band ant.

By the way, this modification resulted in 10+ Watts output from a Microwave Modules MMT 144/28 when used with an IC-745. Previous to this, the output was about 1 Watt. So the modification works very well! One additional note: When you make such modifications to your radio you void the warranty. This is standard practice of all ham equipment manufacturers. It's no big deal, really. Just wait until your unit is out of warranty (usually 90 days) if you have any doubts. This modification will not degrade the performance of your IC-740/745 one iota and in fact makes it more useful—at least as far as transverter owners are concerned. Case in point: I use both solid-state and tube-type amplifiers after my transverters. The problem of drive levels arises in that while the solid-state amplifiers need the full 10 Watts or more for full power, the tube amplifiers, which are grid-driven, require much less drive, usually around 2 Watts. Having the transmit and receive lines split at 28 MHz permits the use of a step attenuator to allow either configuration.

My apologies to all who were puzzled by some typos in the December, 1985, column about the AM-6155 amplifiers. First of all, the optional bias circuit came out of left field. Not only did the zener position get reversed, but also the adjustable pot was left out of the circuit and the text specifies the wrong value for the series resistor. Whew! Let's try it again.

Fig. 1 shows the circuit as it should have appeared. This circuit is not new and has been used in many amplifiers. It has even appeared in the *ARRL Handbook*. I have printed it here in case you wish to control the standby and idling-bias current for the 8930 tube used in the AM-6155 in a safe, reliable manner. The suggested mods for AF1T break the screen-voltage line to cut off plate current. Either way will work. Incidentally, the value of the zener is not critical. I've used anywhere from 33 volts up to 56 volts, but it should be about 5 Watts to be safe. The 5000-Ohm, 2-Watt potentiometer is a fairly common item.

If you go for the optional bias circuit, test it by grounding J1 with the plate voltage off and measure the voltage at the grid. It should vary from -130 volts or so down to about -56 volts (minimum resistance of R2). The contacts for closing J1 could be derived from your antenna relay at the back of the amplifier. A DowKey relay would be appropriate here.

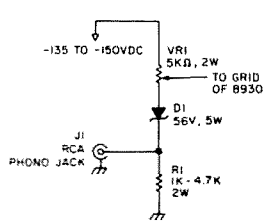

Fig. 1. The optional bias circuit as it should have appeared in December's column on AM-6155 amplifiers.

I should also add that the plate-idling current is adjustable from the top cover and is marked accordingly. If you choose to lift the screen voltage to put the amplifier in standby, then you need only to set this control for the correct idling current, which typically is 90 milliamperes. Some of the stock units come with the idling bias set much higher, but in the original amplifiers 10 Watts of drive provided only 50 to 60 Watts of output—largely due to the input circuit being severely undercoupled to the grid of the 9830 tube. My guess is that the units were set to draw almost 150 mA of idling current, since two that I have seen exhibited this condition before they were modified. However, the listed modifications make the amplifier much more efficient, since much less drive is required to provide equivalent output.

One last correction: The 3.3-pF input capacitor should be shunted with 18–20 pF of capacitance, not the input-tuning capacitor, as the text says. Please follow the schematic for the correct modification. Despite these errors, you'll find the conversion of the AM-6155 to 220 MHz rewarding and the time well spent.

Want to put the unit on 144 MHz? (Boy, have I gotten a lot of inquiries on this one!) Here's the data compiled from Dale AF1T and Woody Peitzer AK2F: First, refer to Fig. 2. Locate C1, the 1.8-pF input-coupling capacitor. This needs to be shunted with 7–20 pF of capacitance. You'll have to experiment with the value. Use silver mica 250-volt capacitors where possible, not disc ceramics. Next, locate C2, the 30-pF input-tuning capacitor. This needs to be shunted with 20–30 pF of capacitance. Again, you'll have to try different values. Finally, C3, the 3.3-pF capacitor to the grid of the 8930, needs to be shunted with about 100 pF of capacitance. This value appears to be constant from amplifier to amplifier.

The last thing you'll need to do is locate the plunger assembly marked VHF-UHF. The AM-6155 comes set up for UHF operation, so follow the arrow direction and change the cavity plunger accordingly. This shaft has a slide lock on

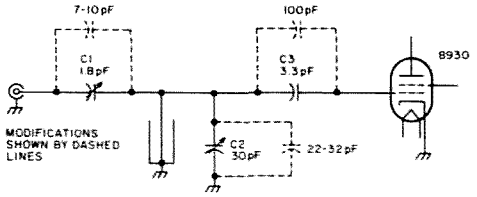

Fig. 2. Modifications necessary for putting 144 MHz on your AM-6155 amplifier.

it to prevent accidental movement. Changing the plunger changes the resonance of the cavity and puts it in the 120–160-MHz range, and setting the turns counter on the output tuning to about 050 to 070 may get you in the ball park quickly when initially tuning up.

One technique that I used when tuning up an AM-6155 for the first time was to bring up the filament and grid voltages, but no plate or screen. Next, I applied a driving source to the input of about 1 Watt and connected a sensitive rf millivoltmeter to the rf output jack. Using this combination, I was able to tune the amplifier for maximum output quite readily. After disconnecting the rf millivoltmeter and connecting a dummy load, it was a simple matter to peak the four controls quickly for maximum output. It also saved a sprained wrist from having to dial away at the slow-turning counter.

Update: Now that I've given the data for the AM-6155 conversion, Fair Radio has gone and sold out all the units they had. Welll Guess I'll just have to mention that they *do* have about a hundred of the AM-6154 VHF cavity amplifier assemblies in stock for about another 50 dollars. These are already tuned for 120–160 MHz but still need additional mods to the Input circuit to increase the coupling at 144 MHz. The critical component there would be C3, and this probably needs to be brought up to about 100-pF capacitance as is the case with the AM-6155 model. I'd appreciate any correspondence from readers (no phone calls, please) who've successfully put these on two meters.

It goes without saying, I guess, that the AM-6154 can be converted up to 200 MHz. You'll need to set the plunger assembly to the UHF position, as indicated by the arrows on the cavity shell. The next step would be to modify the input circuit as per the December article. Again, conversion data from those who've pulled a 6154 up to 220 MHz would be greatly appreciated, and I'll publish it here as soon as I receive same.

One last note regarding Fair Radio: In the recent fall/winter supplement is the #A5–TUN–CAV, which is nothing more than a tunable VHF/UHF cavity using a 4CX250B and 6818 driver tube. No power supply is included. Originally part of an FAA TV-36/TU-9, 50-Watt-transmitter assembly (shades of the AM-6155), the unit comes complete with tubes for about $95. The cavity is silver plated with three tuning controls, including one with a turns counter in it like the 6155.

If you're handy, you can build a power supply for this unit and will need to supply the following voltages: +2000 V dc, +300 V dc, 6.0 volts ac for the filaments, and -135 volts adjustable for the bias. You won't need to use the 6818 tube, but the input circuit is probably undercoupled as in the AM-6155 and 6154. Some modification of the input circuit should result in an amplifier capable of 300–400 Watts output with 3–4-Watts drive In Class AB_1. The bias circuit in Fig. 1 could be used here. The nice thing about this amplifier is that 4CX250Bs are relatively cheap and plentiful at hamfests. I recently bought two that looked brand-new (and worked that way) for a total of $10.

Again, any conversion data is solicited from readers. I might even order one of these myself and fool around with it. The UHF capability suggests possible use on 220 MHz as well. As you can see, there's a lot of surplus out there that can be put to use right away by the VHF enthusiast. Incidentally, I published the address before, but I'll do it again for Fair Radio: 1016 E. Eureka Street, PO Box 1105, Lima OH 45802.

An interesting publication has crossed my desk. It's *VHF Communications*, which is published four times a year in Germany and contains many useful articles, some of which pertain to construction projects. The late Terry Bittan G3JVQ/DJ0BQ was its publisher until his death in early 1985; I'm not sure who is putting the magazine out at this time. This particular issue featured articles on building your own MeteoSat converter for receiving weather pictures from space, as well as a fast-scan TV converter to display them. Also mentioned were projects for a 2–200-MHz wattmeter, compact BNC attenuators using chip resistors, and a 2.3-GHz prescaler for frequency counters.

Most of these articles referenced a listing at the back of the magazine for parts and assembled units. Several of the kits are offered directly through *VHF Communications* by mail order. The articles are well-written and the layout features clean schematics, as well as parts overlays and PC-board templates. The only catch is that many of the parts used are European in origin and finding them here is a bit of a bother. Regardless, the magazine makes for interesting reading. *VHF Communications* is available in the US from U.V. Comms, PO Box 432, Lanham MD 20706. I didn't find a subscription rate but it would appear to be around $17 per year based on the DM-to-dollar conversion.

By the time you read this, the ARRL VHF Sweepstakes will have come and gone, but I hope that many of you took a little time and got on the air to make a few QSOs. This is by far the largest VHF contest (well, what else is there to do in January?) and draws several hundred entries. One good thing about contests is that they lead to increased activity on many quiet bands, such as 220 and 1296 MHz. It's also a great time to make a performance check of your station equipment. I've aligned many a preamplifier, converter, and transverter during a contest (sometimes when I didn't plan on it). There sure are a lot of weak signals to choose from.

Missed the VHF SS? There's the ARRL Spring Sprints which start in April. These basically are a series of monoband one-night contests with 4-hour periods, hence the name "sprint." Details are available in *QST*. Again, these are fun ways to spend an evening, really finding out just how much activity is around on your favorite band.

MORSE CODE TAPES

You read about it first in the New Products section of ham radio:

"Many methods have been offered for learning Morse Code, some good and some not so good. **This is a good one.**"

→ Have you plateaued at 10-13 WPM? MASTER the code in 40% less time.

→ The method based on the scientific principles of Skill Acquisition and Perceptual Learning

Adopted by the U.S. MILITARY as the new training standard

Four cassettes teach the entire alphabet in 25 trials at 20 WPM!
Includes numbers, punctuation, special characters, and an all new intro tape.

73-2

Not much further down the road lies the ARRL June VHF QSO Party, the first of the big four summer contests. This is the second most popular VHF contest with many stations traipsing around to various hilltops and grid squares to give out points.

Close on its heels is the *CQ* Worldwide VHF WPX contest in July. The WPX ran for the first time last July and received an astounding 460+ entries from all over the globe. This is the only contest that uses prefixes (WB2, DL0, JH1, G3, VE4, etc.) for multipliers and has met with very enthusiastic response. I am co-chairman of the *CQ* VHF WPX Contest Committee with Steve Katz WB2IK of *CQ* magazine and will mention from time to time some of the more interesting scores and stories from this event.

Bringing up the rear are the ARRL UHF Contest in August and the ARRL September VHF QSO Party. The latter is often noted for its wild tropo openings, such as in 1984 when the Massachusetts-to-Georgia path was worked on 1296 MHz! So, you can see that there are plenty of opportunities to "exercise" your station and have fun doing it as well.

Although VHF and UHF contesters are every bit as serious as HF contesters (maybe even more), the bands are never as hectic and with Sporadic-E, Aurora, Meteor Scatter, and Tropo Scatter awaiting you there are plenty of surprises. Just wait until about five years from now when the sunspot cycle is on the way up and you start hearing G3s coming through your speaker! (Not to mention LU, YV, XE, VP, and possibly DL/F/EA and other Europeans as well.)

This might be a good time to shop around for a used 50-MHz rig, such as the ICOM IC-551 and 551D series. Many of these are showing up at flea markets since their owners have lost interest with the declining sunspot cycle. For those who don't know, the IC-551 is a 10-Watt multimode with built-in power supply, while the 551D runs 80-Watts output and requires a separate supply. Unlike most multimode radios, they were designed for SSB/CW operation, with FM an add-on. The receiver performance is most satisfactory, although it can be improved considerably with a good MOSFET preamplifier.

Update #2: Late word from Ivars Lauzums KC2PX brings the news that hams in Great Britain have been granted 50-MHz privileges—the first step, hopefully, to wide-scale 6-meter operation on the European continent.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards or odd-sized scraps of paper. Please type or print your request (neatly!, double-spaced, on an 8-1/2 x 11 sheet of paper and use upper- and lower-case letters where appropriate). Also, please make a 1 look like a 1 not an l—which could be an el or an eye, and so on. Hard as it may be to believe, we are not familiar with every piece of equipment ever manufactured on Earth! Thanks for your cooperation.

I am looking tor a manual for a National NC-183D general-coverage shortwave receiver.

Several years ago I was referred to a place in Missouri which carried manuals and schematics for older equipment. Does anyone have the name and address of this or of any place that would have them?

Lawrence W. Joy NO0S
586 Fremont Drive
Littleton CO 80120

I would like to locate a Johnson model #122 vfo and a Johnson #6N2 vfo.

Joseph Karr N9FAU
3800 Cheyenne Avenue
Racine WI 53404

If anyone has a copy (in good condition) of the book, *The Complete Handbook of Slow-Scan TV*, by Dave Ingram K4TWJ (Tab Book No. 859) and wants to sell it, please write and tell me your price. I will pay in advance.

Carlos Urbina Pacheco
Calle 14 No. 1128 Norte
Torreon, Coahuila 27000
Mexico

I need the manual or schematic and alignment procedures for a John Fluke differential voltmeter, model 803D/AG. I will pay postage and copying costs. Please write before sending any material.

Robert P. Whitted DA2EB
PO Box 2567
APO NY 09123

A ham radio/computer club wishes someone to donate a working or non-working disk drive for use in the club. The drive needed is for either a Radio Shack TRS-80-II color computer or an Atari 800XL computer.

Howard S. Bacon
213 Holly Avenue
So. Pittsburg TN 37380

I want to start a newsletter on slow-scan TV/radio facsimile/satellite weather photos. Anyone who might wish to write for it should write to me.

Howard S. Bacon
213 Holly Avenue
So. Pittsburg TN 37380

I am looking for support brackets for the AN/URA-17 comparator-converter unit.

Charles T. Huth
229 Melmore Street
Tiffin OH 44883

I need the instructions and schematics for the Macrotronics Terminall RTTY program. I presently have version 2.0 manufactured in 1982. I am also interested in any and all software for RTTY for the Model IV TRS-80 computer.

The Dayton Amateur Radio Association, Inc., will sponsor the Dayton Hamvention on April 25–27, 1986, at the Hara Arena and Exhibition Center, Dayton OH. Admission, valid for all three days, is $8.00 in advance, $10.00 at the door. Banquet tickets: $14.00 in advance, $16.00 at the door *if available.* Ladies luncheon, $6.75. Advance sale deadlines: April 5 (Canada) and April 12 (USA). Roy Neal K6DUE will be the banquet speaker.

Giant Flea Market: noon Friday through Sunday. *All spaces sold out.*

Technical forums on: personal computer, packet radio, ARRL, AMSAT, antennas, RTTY, SSTV/ATV, FCC, electrical safety, and other topics. CW Awards—try to break the 72.5-wpm world record!

License exams: Novice through Extra, by reservation only. Send before March 29: completed form 610, a copy of your present license, and check or money order for $4.25 payable to ARRL/VEC, to: License Exam, Attn. Tom Holmes, 8830 Windbluff Pt., Dayton OH 45459.

Send nominations for "Radio Amateur of the Year," "Special Achievement," and/or "Technical Achievement" Awards, to Awards Chairman, Box 44, Dayton OH 45401, before April 1.

For further information, see HAMVENTION ad on page 15.

FITCHBURG MA
APR 26

The Montachusett Amateur Radio Association will hold Flea Market Saturday, April 26 at the Knights of Columbus Hall on Electric Avenue, Fitchburg MA. Doors open at 8 am for sellers and 9:30 am to 3 pm for buyers. Talk-in on 144.85/145.45 and 146.52. Admission is $1; tables $8 each. For table reservations send check payable to M.A.R.A., c/o James Beauregard, 7 Mountain Ave., Fitchburg MA 01420.

CEDARBURG WI
MAY 3

The Ozaukee Radio Club, Inc., will sponsor its 8th annual Cedarburg Swapfest on Saturday, May 3, from 8 am to 1 pm at the Circle B Recreation Center, Highway 60 and County I, in Cedarburg WI (20 miles north of Milwaukee). Admission is $2 in advance, $3 at the door. Four-foot tables are $3 each. Sellers will be admitted at 7 am for setup. For more information, send a business size SASE to 1986 ORC SWAPFEST, 101 E. Clay St., Saukville WI 53080.

GRAND JUNCTION CO
MAY 10

The Grand Mesa Repeater Society will hold the Seventh Annual Western Slope Amateur Radio and Computer Swapfest on Saturday, May 10, 1986, from 9:00 am to 4:00 pm at the National Guard Armory, 482-28 Road, Grand Junction CO. Admission is free and swap tables are $5.00 each. Features will include an indoor swapfest, amateur radio exams, a packet radio demonstration, an auction, and refreshments. Talk-in on 146.82 and 449.20. To reserve a swap table and for further information, send an SASE to Larry S. Brooks WBØECV, 3185 Bunting Ave., Grand Junction CO 81504, or call (303)-434-5603.

HARTWELL GA
MAY 17–18

The Lake Hartwell Hamfest, May 17–18, sponsored by Toccoa (Hartwell GA and Anderson SC) ARC, will be held at the Hartwell Group Camp, Hwy 29, 20 miles west of Anderson SC and 3 miles east of Hartwell GA. Campground opens by 6 pm, May 16. Talk-in on 146.295 + 600, 146.19/.79, 147.93/.33. Free flea market space. Tickets and information available from M. A. Counsell W1BNS, 215 Nottingham Way, Anderson SC 29621; (803)-261-7018.

HBØ DXPEDTION
MAY 22–JUN 2

The Wiesbaden Amateur Radio Club, WiesARC, an ARRL affiliated club from West Germany, will be found on the air again from Liechtenstein during the club's eleventh annual DXpedition from May 22 through June 2, 1986. The club will be operating the HBØ/DA1WA callsign on all bands using both CW and SSB. Each contact with DA1WA counts heavily toward the club's Urkunde (award) Certificate. Urkunde information may be obtained from the QSL managers. US and Canadian stations QSL (with 22-cent SASE) via regular US mail (22 cents) to Steve Hutchins KN6G/DA2HS, Box 4205, APO NY 09633-5374. All others QSL with IRC via Hugo Jakobljevich, Im Weinberg 10, D-6200 Wiesbaden-Auringen, West Germany.

CAMBRIDGE MA
JUN 16–20

The Massachusetts Institute of Technology is again offering a program of applied imaging, "Techniques in High-Speed Photography and Videography." The special summer program will be held from June 16 to 20. This photoinstrumentation program of complimentary lectures and laboratory experiences is under the direction of C. E. Miller and Dr. Harold E. Edgerton. It includes two full days in the MIT Stroboscopic Light Lab. For further details, contact: Director of the Summer Session, E19-356, Massachusetts Institute of Technology, Cambridge MA 02139.

AT YOUR SERVICE

In general, I have been very pleased with the improvements in *73 for Radio Amateurs*, and I have continued my subscription. The technical content of your articles has improved. QRX is a good section. I like the format and the covers. The breadth of the material is excellent, from editorials to advertising.

However, you seem to have forgotten that the average age of amateur radio operators is about 46 years. Why have you forced those of us who wear bifocals to get out the magnifying glass?

I am not a printing expert; I don't know how many "points" the type is, but it is too small for lots of us out there.

Keep up the good work with *73*!

Staff Stafford NJ8F
Delaware OH

Don't anybody, *not ever*, *oops—Don't* anybody, *not ever, say that this magazine is not responsive to its readers*—KA1MPM.

MONEY OR LICENSE

I am pleased to have this opportunity to respond to Perry Donham's "What?" editorial in your January issue.

I am among those who agree with Perry's hard-line stand on the issue of ham-band commercialism. The editorial correctly made this point: Most of us do not intentionally use the ham bands for commercial gain.

Last week I heard a K1 refuse to accept a formal piece of traffic on one of the local nets because it had a commercial nature. The W2 holding the message commented, "I thought that it would be OK, since it made it this far." Wrong.

It's your license, your station, your decision.

Donham's self-imposed standard is simple and safe. That is, ask yourself whether "the action could eventually result in money exchanging hands."

I keep a dime tucked away inside my wallet next to my ham license. That reminds me that sometimes I need to decide which one to use.

Regards, and 73,

Dave Bushong KZ1O
Nashua NH

ONE MORE CHOICE

I have come up with what I believe to be a more fair and equitable system for licensing amateurs. It may sound like a rehashing of the no-code license, but there is an important difference.

In my system, there would be a basic amateur license with either no operating privileges or just 50 kHz on the 50- and/or 220 MHz bands with full code and phone privileges. This would give the newcomer a taste of what can be done as an amateur. Then higher licenses would be by endorsements by passing the appropriate examination elements.

For example, passage of exam elements 1A, 1B, and 1C would give only code privileges on the respective Novice, General and Advanced code subbands. Passage of exam elements 3, 4A, and 4B would give phone privileges on the respective Technician, General and Advanced phone bands. The requirements for the basic amateur license would be element 2 and a 100% reproduction of the Morse code, matching the representations with the appropriate character. (Most amateurs who operate only phone cannot copy the code at their license level anyway.)

This way, they would at least know it. And this would allow people who cannot copy code due to some handicap, the chance for a license. Then, to keep the Extra bands sacred, you would have to have endorsements for both 4B and 1C to have privileges there.

I hope that you will publish this so that the amateur community will have one more alternative to choose from.

Steve Sulze WD0GIY
Crestwood MO

HELP HOBBY GROW

I've been reading some negative comments about the proposals before the FCC to enhance Novice privileges. Both the ARRL's RM-5038 and my own RM-5022 through RM-5025 request small band segments, restricted power, and the inclusion of digital modes. We never intended to "give the store away," nor do we expect the FCC to grant all the privileges we requested. Our common interest is the growth of our hobby in a responsible way.

I fail to see what you opposers fear. There will be no loss of "higher class" privileges. Who protested the access we gained to 30 meters, or 12 meters, or 902 MHz? The Novice operators have gained nothing. The Technicians gained a band but it is not really an incentive to Novices to upgrade. The big incentive to Novices seems to be 2-meter FM, and that is why my proposal did not include that band.

The ARRL's proposal includes more kHz than mine and is less practical with its inclusion of the 1246-MHz band. I have seen my proposal mentioned in only one publication (*Worldradio*, September, 1985) and have received no comments. My aim is to offer nonhams a Novice license that will attract intelligent adults and young people. We need computer enthusiasts, story tellers, teachers, students, accountants, laborers, etc. Our record shows that we cannot lure them in any numbers with our CW-only Novice license.

Teach a Novice or an upgrade course like I do and you will see the work that goes into each new ham. You old-timers may forget that ham radio and electronics are a new language to the non-ham. We can help squash the myth that equipment is too expensive if we offer new hams phone and digital modes as well as CW. The equipment will be of more use and will seem a better value. Besides, Novices really do *earn* a license.

If, after reading this, you still think enhanced Novice privileges are a bad idea, go read the actual proposals and then comment to the FCC.

MACHT NICHTS NOW!

I recently encountered a problem which I feel should be brought to the attention of the amateur group for others contemplating a visit, or residence in Italy.

We moved to Italy from Niagara Falls in December of 1984. In January of 1985, I submitted the necessary paperwork for an Italian license.

Sometime later, I received a

temporary license and more paperwork, along with a request for two "certified photos" plus twenty US dollars, cash only. Again, much later, I received the photos *back* because they were written on.

"How else can you certify them?" asked the US certifying official?

Straightened *that* out supposedly, and *later* received another temporary license application.

Here it is, December of 1985, and two weeks ago received another very official-looking piece of paper that turns out to be *another* temporary permit along with a letter to the effect, "congratulations, *now* you can begin the application process for obtaining a permanent Italian license!"

Macht nichts now! We moved back to Germany where, thank goodness, the amateur licensing system is *much* more efficient—it took me about 30 minutes to get my license versus the eleven-months-and-still-in-process in Italy. I think that after they received the US *cash*, that was the prime concern. You were then relegated to the Italian paper mill.

I would strongly advise any potential radio-amateur visitors to Italy to thoroughly investigate the procedures before attempting reciprocal licensing! To me it was very disappointing.

Jerry S. Richter KI1WY/DA2RI
Munich, West Germany

WEIRDNESS REVISITED

Great editorial in the January issue! May I add some thoughts of my own?

I guess this could be construed as picking on the simplex autopatch boys (again), but I wonder—just wonder, mind you—about the propriety of the brethren setting up a simpatch system and then charging individual members of the group for the privilege of using it.

You see, if I pay dues to a repeater to keep it up, I am buying the right to keep the system going, and that includes the right to use the repeater, plus its autopatch, its electronic bulletin board, or its remote bases—or all of the above.

The problem with a paid simpatch group is that all you are paying for is the simpatch function, which smacks a lot of competition with the local cellular system—especially if it is abused, which I still think it is in all too many instances. Maybe I'm wrong. Maybe a simpatch can offer other things as well, but I haven't seen that sort of thing actually put into practice.

Now, mind you, I have no serious problem with *repeater* autopatches. I've turned in a couple of DWIs using ours, in the last year, and that is enough to convince me that autopatches are in the public interest, when all is said and done. I just believe that the rise of simpatches may be the beginning of the end for amateur interconnects to the telephone system in any form. And that's not just me talking.

Re the QRX item "Weirdness," we have some retractions to make. Suffice it to say that the intent of the CTIA with regard to S-1667/R-3378 has been terribly misrepresented in the amateur media, much to our embarrassment, I'm afraid. I feel that, as a group, we really blew it with this one, and our credibility has suffered as a result. See the December *'220 NOTES* for details.

That is not to mean that S-1667, *et al*, should be ignored. This is a prime example of a horribly written bill that should be either cleaned up or killed, the question of Right-to-Listen vs. Rights-of-Privacy totally aside. With this question included, I would strongly suggest that a technological solution to the privacy issue is far superior to a political one, and again, I refer you to the December *NOTES*, which should be out in a few days.

Art Reis K9XI
New Lenox IL

DONHAM'S LAW

KW1O's attack on commercialism in the January, 1986 issue of *73* is well stated. There are, in fact, many situations encroaching on the FCC rules on noncommercial use of Amateur Radio.

The problem with Donham's Law is in the "could eventually." How do you allow for the discussion of equipment among hams? Someone will be influenced to go buy something as a result. I say this is too broad in scope.

Then do you say we can't talk about FCC exams under the VEC program since there is a fee charged for registration, and that is certainly "money exchanging hands"?

I think, in general, hams exercise excellent judgment in how they use the air.

Data Book For All Above #'s 2.50

Cypher IV Micro-Controller Kit- $129.50
- 4 MHz, 8-Bit Microprocessor (NAT NS8073)
- Control Basic Interpreter On-Chip
- Auto-Start Operation At Power-On
- Fast 16-Bit Multiply And Divide
- RS-232, Supports CRT & Serial Link
- 24 Bi-Directional I/O Lines (8255A)
- RAM Memory-2K Expandable To 16K
- Eprom Memory Expandable To 16K
- Built In Eprom Programmer
- Parr (Centronix) Printer Interface
- Optional Real-Time Clock W/Backup

Pay TV Hardware Installation Kit Blow Out As Low As $2.95 + $3.50 Shipping Per Unit
All Kits Contain 5 F Connectors, 300 to 75 OHM Balun, 300 OHM Terminal Block 2 Ft 75 OHM Patch Cord, 2 Ft 300 OHM Twin Lead Nylon Cable Ties, And UHF Antenna
Model #4124-$2.95 Includes All Of The Above Plus 25 Feet Coaxial Cable And Mounting Hardware For Indoor Wall/Ceiling Installation
Model #4880-$2.95 Includes All Of The Above Plus 25 Feet Coaxial Cable And Attractive Expandable Pole/U-Bolt For Easy Indoor Installation
Model #4845-$3.95 Includes All Of The Above Plus 65 Feet Coaxial Cable And All Necessary U-Bolt Hardware

MODEL 705 Digital Multimeter

DC Voltage	100mV to 1000V
AC Voltage	100mV to 750V
DC Current	0.1mA to 10A
AC Current	0.1mA to 10A
Hi-Lo Resistance	0.1Ω to 20MΩ
Capacitance	1pF to 20mF
Diode Test	forward voltage testing
Hfe test	transistor testing

$51.95

UHF-TV PREAMP
(As featured in Radio Electronics March/May articles, 1982)
This inexpensive antenna mounted preamp can add more than 25 dB of gain to your system. Lots of satisfied customers and repeat orders for this high quality kit, which includes all component parts, PC BD, Case, Power Supply and Balun $34.50
Assembled Version $57.50

Terms: MICRO-MART accepts Visa, MC and telephone COD's. Minimum order $10.00. Shipping—U.S. orders, $2.00. Canada and other countries $3.50 (includes ins.) Shipping rate adjusted where applicable. NJ residents add 6% sales tax.
MICRO-MART • 508 CENTRAL AVE., WESTFIELD, NJ 07090 • (201) 654-6006

73 INTERNATIONAL

Just because I started this column as a result of visiting DX hams is no reason you shouldn't put in your 2¢ worth and let me know what DX news you find most interesting. My inclination is to have DX ops tell us what they think is interesting—how we can get permission to operate if we're fortunate enough to visit—any coming DXpeditions—what's doing with repeaters—things like that. What do YOU find most interesting? Since we have a world hobby, I think you'll be as interested as I in what is going on. If nothing else, it gives us something to talk about on the air which, from what I'm hearing these days, can't hurt.

—Wayne.

VK5 AMATEURS GO RAIL MOBILE

The idea to work Rail Mobile on the Trans-Australian Railway from Adelaide to Perth developed from a suggestion that two Australian National-employed amateurs, Keith VK5VAX and Graham VK5BGP, undertake the activity in their off-duty period, with the approval of Australian National. The proposal that eventually gained acceptance involved the allocation of two Australian National tickets, the provision of a Wegman 1st class coach for the trip, with media publicity to be sought by Australian National promotions officers, Mr. Bob Sampson and Mr. John Beatty.

The SA Division, through its Jubilee 150 Coordinator, Graham VK5AOZ, was asked to provide equipment and antenna configurations within the parameters of height, location, and installation set by Australian National for the Wegman Coach. The group of three amateurs, Alan Roocroft VK5ZN, Peter Koen VK5BPA, Secretary of 2nd Adelaide Scout ARC, and Graham Horlin-Smith VK5AOZ, were assisted by Keith Pattman VK5NAX, a senior conductor on the outward journey from the Adelaide Terminal departure on Wednesday, September 11, at 12:40 pm.

The turn-around trip left Perth Saturday, September 14, to reach Adelaide on Monday the 16th at 5 pm. Graham VK5BGP joined the group for the return home from Kalgoorlie and also to assist in breaks from his conductor's duties on the train. Five amateurs piloted the rigs during the trip.

Several antennas were installed on Saturday the 7th, including a 25m longwire, a 40m Hustler Whip and a tapped 40m Whip. Two-meter equipment, a Kenwood TR-2500 hand-held with a base supply unit, and a KYOKUTO 144-10FX R2 (FM) with a home-brew scanner, and a 60-Watt amplifier worked from a quarter-wave magna base vertical. A Kenwood TS-93X and a TS-820 provided the fire power for the open wire and the verticals above the carriage roof.

The optimum height of all antennas was fixed at 0.5 meters to allow for clearances of bridges and tunnels, although it was possible to lift the configurations to 1.4 meters between Port Pirie and Kalgoorlie. The problem areas really amounted only to a total distance of 10 km close in to the Keswick and Perth terminals, out of a total journey of 5.320 km. The difficulty in real terms, to make antenna changes, was time and suitable stopovers to periscope the antennas and thereby improve the capabilities of the equipment from the railway mobile location.

The *purpose* of the activity, mutually agreed by the WIA (SA Division) and Australian National, was to give promotion to the two organizations—the Trans-Australian Railway link between Adelaide and Perth, and the hobby of amateur radio. In addition, of a secondary nature, was the promotion of SA and its Jubilee 150 celebrations, including the Grand Prix held in Adelaide in November, 1985. These objectives were as follows:

- To acknowledge Westrails link with Australian National on the WA side of the border,
- To record a first for amateur radio to work Rail Mobile across the Nullarbor, and
- To demonstrate amateur communications as a valuable alternative means of world communications and to provide meaningful goodwill exchanges with people around the world.

The promotional purpose of the five-day round trip was acknowledged by the world of amateur radio by the use of the callsign V15JSA/Rail Mobile (Trans-Australian). V1=special event, WIA (75th Anniversary), oldest AR group in the world, 5=South Australia, JSA=special suffix allocation for *Jubilee South Australia* and Rail Mobile, courtesy of Australian National.

The uniqueness of the special callsign and the location of the amateur-radio stations on the Trans-Australian, it was hoped, would attract special attention to the activity, and it surely did just that!

Amateur displays and public relations were shared jointly by the amateurs making the trip, with overall coordination responsibilities given to Peter Koen, SA's Divisional "Mr. Magic." Armed to the gunwales with posters, awards, QSL cards, banners, flags, and my copies of a home-brew screen print: smcsa amateurs *live* across the nullarborsmc.

The print surpassed any theater coming-attraction poster. Peter's personal professional promotion provided the excellent communications links needed between amateur hobbyists, passengers, visitors, VIPs, Australian National Staff, and flora and fauna of the Nullarbor alike. When out of range of all known two-meter repeaters along the way, Peter did most of the talking to the passengers and captured, on video and camera, a documentary of the lively amateurs' "Pilgrim's Progress."

The identification and project mission of the amateur-radio-coach ADO83 was boldly stated on the platform side of the 25-meter super-sleeper carriage: SA Amateur—World Communications—with Australian National—Across the Nullarbor.

Even the kangaroos, emus, and dingoes, if they could read, and the occasional passerby en route, would have been impressed, if not by the message and callsigns, then by the novel antennas (25-meter longwire and traditional verticals) which graced the roof of the carriage.

The longwire was supported half a meter above the roof by 10 spaced, half-inch, pieces of varnished dowling from a 1-inch piece of water pipe sleeved with dowling at each end of the coach, which were bolted into steel brackets used for flags or external lighting back in the coach's preretirement days. The verticals were bracketed to hand rails on each side of the entrance and exit passenger doors.

The amateurs transformed three adjoining sleeping berths into QTH-like shacks with QSL cards from all over the world, displays of well-earned awards, and even stern reminders of schedules, repeater listings, operating cue cards, amateur photograph displays, and even more stern reminders of footy (Aussi Rules) affiliations.

Card tables supported rigs, working equipment, and logs—nothing new to the familiar sight of a home QTH inside a house, or at a safe distance from the XYL's domain. Comfortable portable beds made working in the horizontal plane with a good view of the landscape outside an excellent prospect. Indeed, it was a worthy scientific experiment to pilot amateur-radio rigs from unusual positions.

What were the results and eventual outcomes?

- A satisfactory number of exchanges—in excess of 500—was made along the way. The bulk were with Australian stations but contacts with the USA, Japan, USSR, NZ, Canary Islands, Indonesia,and South Africa were made.
- Excellent media coverage afforded by television and commercial radio stations.
- Australian National should be well-pleased with the interest sustained by the presence of amateur-radio stations on the Trans-Australian, the goodwill and the exchanges with passengers, also with the overall media presentations in Adelaide and Sydney.
- The use of both VI5JSA and VK75A/Rail Mobile callsigns stimulated the anticipated expected responses.
- Secondary priorities and objectives were successfully achieved by way of the special callsigns with due attention given to SA and its forthcoming activities in 1986.
- The support, back-up, and interest was willingly shared by all Australian national and Westrail per-

sonnel, which made the trip all the more memorable and worthwhile. The travelers were thrilled with the personal attention and the super togetherness engendered.

•Amateur radio gains were significant in terms of promotion and sharing the hobby with the general public, in particular the opportune meeting, and links established with the CARC (Goldfields Amateur Radio Club) and the WIA (WA Division), thus reaffirming the excellent rapport that already exists between amateurs.

•The GARC group of Kalgoorlie presented a framed Gold Award to the travelers, which in turn was presented to SA Divisional President Dick Boxall VK5ARZ—a very beautiful momento of the historic trip. A welcoming "computerized" banner to the SA amateurs at Kalgoorlie was greatly appreciated.

•The well-documented video and camera story of the trip across the Nullarbor, the tapes of the VK6 broadcast, and taped interviews in transit provide a live history for future use.

The overall results of the lighting preparation and culmination (less than three weeks from acceptance to close), were most rewarding. It was a job well done by a very professional group of amateurs led by Bob Allan VK5BJA. The experimentation in rail-mobile antennas and promotional activities carried out by the group was new, save the excellent pioneer work achieved by Bill Main VK6ZX back in the late '70s.

GREAT BRITAIN

Jeff Maynard G4EJA

Hawley Hill
Camberley, GU17 9JQ
England

Like many societies concerned with leisure-time activities, the RSGB (Radio Society of Great Britain) is largely under the control of amateurs. There are, of course, full-time paid administrators to run the office and undertake the requirements that the law imposes (the RSGB, at least, is registered as a company).

But the policy-making group, the Society Council, is selected from the membership at large. The Society president is selected by the Council. Over a period of years, one sees the same names appearing as potential or actual council members, committee members, and/or contributors to *Rad Com* (the society's journal, *Radio Communication*), and so on.

Is this a good thing or a bad thing? I think it is certainly true that an element of change, particularly when it involves new blood, is a good thing. People do get set in their ways (and become guilty, perhaps, of being unable to see the woods for the trees), and an influx of new and fresh ideas can only help to bring progress to any organization.

However, that is not to say that wholesale change is good. There needs to be continuity and experience and maturity (and even the steadying hand of elder statesmen). In other words, a balance is wanted between the new and the experienced.

So it has generally been in the RSGB for a great many years. But not for much longer if three members get their way. Messrs. Lundegard G3GJW, Smith G4AJJ, and Crosland G6JNS have ruffled a few feathers with their circulation of documents calling for broad changes in the Society.

I do not wish to bore you with the details (of which there are many) but, instead, will summarize their main point. This seems to be that the length of service of any one individual in a range of posts shall be limited (they suggest six years cumulative service). This, of course, would have the effect of removing all the old hands.

The RSGB has risen to the challenge and produced a lengthy rebuttal of the proposals. I think this is a mistake because the action looks defensive and suggests that there is something for "the few" to protect.

You will note that I have avoided picking sides. I really do not want to be drawn into the argument which inevitably will follow now in the public eye (in the columns of *Rad Com*, if nowhere else). However, I will say that I appreciate the efforts of my fellow amateurs who devote a lot of their time and energy to making my hobby more enjoyable (and that of a lot of other people—at the end of October there were 27,900 Class-A licenses and 27,780 Class-B licenses in force in the UK).

With the imminent availability of the 50-MHz band to all UK amateurs, the RSGB has produced a band plan. This is as follows, and any comments on it should be sent to G3ZNY.

50.000–50.100—CW only
50.02–50.08—Beacons
50.100–50.400—Narrowband modes
50.110—DX Calling
50.200—SSB activity
50.300—CW MS
50.350—SSB MS
50.400–50.500—All Modes

For those of you equipped with a V23 modem (Viewdata type, 75/1200 bps), the RSGB is operating an experimental "Databox." The telephone number from the US is 44 707 52242.

NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

As promised in my last column, I am able to bring readers a report on the IARU Region III Conference held in Auckland, New Zealand, Nov. 12-17, 1985, through the courtesy of *Break-In* magazine reporters, Craig Crawford ZL3TLB and Scott Campbell ZL3NR. They made their notes available to me as I was unable to be present at the conference.

It would be difficult to find a more picturesque venue than the Rose Park Hotel in Parnell, Auckland. This modern and spacious hotel is directly opposite the famous Parnell Rose Gardens, where the roses were just coming up to full bloom. From Saturday the 9th there was a scene of frenzied activity as the administration team, ably led by Arthur ZL1HV, worked to prepare everything in time for the opening.

The behind-the-scene administrative workers, led by Neville ZL2AKV, NZART General Secretary, typed, photocopied, and collated the material for the papers to be presented to the Conference (which had escalated from 69 to 85), and inserted them into the well-filled folder for the 70 delegates and observers. Neville was assisted by Shirley ZL1BI, Gail ZL2SZ, and Jamie ZL2NN.

The first batch of overseas delegates arrived at 8 pm on Sunday evening on a flight from Melbourne where they had attended WIA's 75th Anniversary Dinner the previous night. The 29 arrivals were whisked up to the Manukau Room of the International Terminal for a formal welcome.

A surprise for many of them was being presented with an amateur-radio license from within the special callsign group of ZM0ZAA to ZM0ZZZ, plus 100 customized pictorial QSL cards. Some of the visitors made their first QSOs traveling from the airport to the hotel. The ladies accompanying the delegates were not forgotten—they found well-filled satchels in their hotel rooms with information about the Auckland area, conference badges, and general information about the entertainment especially for them during the time their men were in conference.

Some weary, jet-lagged bodies surfaced early morning. Fortunately for most delegates, this was to be a quiet day. For some however, the main business was the continuation of the IARU Administrative Council meeting which had started in Melbourne the previous Friday. This meeting was chaired by Dick W1RU, and attended by K1ZZ, JH1VQR, 9V1RH, VK3KI, W0BWL, and YV5BPG. Ignoring meal breaks, they labored from 9 am until 7:30 pm.

1985
IARU
NZ 85
REGION 3
CONFERENCE
AUCKLAND • NEW ZEALAND

The ladies, with some of the local people, spent the morning at Kelly Tarlton's excellent Underwater World, a huge aquarium built within Auckland's old sewage tanks. Sharks, sting-rays, octopi, and many species of local fish swam around and over the transparent walk-through tunnel system. In the afternoon they visited the Begonia House of the nearby Winter Gardens.

On Tuesday morning the Region III directors met at Rose Park Hotel. Masayoshi Fujioka JM1UXU, Keigo Komuro JA1KAB, Tsuyako Miyagi, Michael Owen VK3KI, David Rankin 9V1RH, and Arthur Godfrey ZL1HV, debated for much of the day.

Late Tuesday, after airline- and customs-clearance delays, the delegations from Korea, Japan,

Delegates and officials to the 6th IARU Region III Association Conference, Auckland, New Zealand, November, 1985. Photo courtesy of Break In, *NZART official magazine.*

Indonesia, and China arrived. Also on this flight was David Evans G3OUF, general manager of RSGB. The final group of six, including Dick Butler, the secretary general of ITI arrived at 10 pm.

At last, after many hours of preparation, all delegates and observers were present, and the 16,000 pages of documentation were ready for the big event.

The conference got under way at 9:30 am with the official opening. Region III secretary, Masayoshi Fujioka JM1UXU, chaired the opening ceremony and officially welcomed the delegates. Terry Carrell ZL3QL addressed the gathering as president of the host country, and introduced Dame Dath Tizard, the Mayor of Auckland, who, after welcoming them to the city of Auckland, lightheartedly advised that she had arranged excellent weather for the duration of the Conference.

Other speakers were the Honorable Jonathon Hunt, Postmaster-General, and Dick Butler. The Assistant Director General of the New Zealand Post Office, Derek Rose, gave an impromptu speech amplifying the Minister's remarks, and finally Dick Baldwin W1RU spoke thanking the previous speakers for their kind remarks.

After morning tea (coffee break), the first of the 17 90-minute sessions commenced. Present at the sessions were 60 delegates and observers from 11 countries. A very special welcome was made to the delegation from the People's Republic of China, Mr. Wang Xun and Mr. Huang Yongliang, officially attending an amateur-radio conference for the first time.

As is tradition at such conferences, the president of the host society was nominated as conference chairman. This was passed with acclamation, and Terry Carrell ZL3QL took the chair. The Region III Secretary, Masayoshi Fujioka JM1UXU, was nominated as conference secretary, also by acclamation. The Credentials Committee, one of the various committees essential for the smooth running of the conference, reported that all attending Societies were correctly represented, and that proxies for Bangladesh, Hong Kong, Pakistan, Singapore, and the Philippines were in order.

The first of the 93 papers to be received and discussed was the report from Region III secretary, who was happy to announce that the Amateur Radio Club of Tonga, (ARCOT) had just been admitted as the 24th member society of Region III.

Formal reports from the four Region III directors were tabled and accepted with little discussion as lunch was ready.

The various member societies then reported on their activities, and here are some items of interest from the reports. JARL indicated concern at the decline in the rate of increase of membership, down to 10,000 per year. PNGARS (Papua New Guinea) believed they now had the highest amateur repeater in the region, atop Mt. Albert Edward at 3,990 meters above sea level.

ARRL reported on behalf of 37 of the members in Region III territories, noting after a decline in the number of amateurs joining ARRL, they were now experiencing a 5-percent growth. ORARI (Indonesia) announced a new Radio Regs just introduced which included creation of a no-code license. They also hoped to work toward a reciprocal licensing agreement with New Zealand.

WIA (Australia) were happy to report that most of the WIA submissions had been acted upon in the new Regulations and Radio Communications Act which were introduced recently. WIA, representing SARTS (Singapore), mentioned that many apartment dwellers there must pay extra rent for their antennas.

MARTS (Malaysia) entertainingly explained the difficulty they have with authorities. It was reported that the administration's policy seems to have changed from "find out what they are doing and stop them" to "find out where they are going so we can lead them." Until recently, even communications receivers for SWLs were illegal in Malaysia.

RSGB announced only a few days previously that approval had been given for amateurs in Britain to conduct Morse testing as from April, 1986.

KARL (Korea) announced permission had been given for a station to operate from the 1988 Olympic Games to handle third-party traffic for games' participants.

Commenting on the FARA (Fiji) report, ITU Secretary General Dick Butler spoke of his involvement in setting up the Telecommunications Training Center in Fiji and the encouragement it gives students to obtain their amateur license.

Reports from Region I and II were received and Mr. Butler offered ITU's assistance in setting up volunteer training programs in Region I and II countries also. A report from IARU Administrative Council meeting included their adoption of a policy for extensive preparation for future WARCs, including participation in CCIR activities and also a revision of the 28-MHz beacon system.

Ian Ashley ZL1AOX was invited to speak on packet radio and he expressed the opinion that packet radio be band-planned for the phone portion of each band, as is ATV. Dick Baldwin W1RU advised that Region I is uneasy about the proliferation of packet radio on the bands, especially 20 meters.

The conference then considered six papers dealing with band-planning. After some discussion on each paper, Working Group 1 was set up to review the band plans adopted, especially the 28-MHz band, and the position of packet radio and other special modes in any plan.

An NZART paper urged other Societies to negotiate with their administrations for the release of the band 10.15–10.20 MHz on a local non-interference basis. Some delegates were apprehensive about this action, preferring to gain and live with WARC 79 bands first. The NZART proposal was adopted.

Day 2 of the conference opened with discussion on the usage of the new bands made available through WARC 79 (10, 18, and 24 MHz). It was reported that in Region III 10 member societies had access to the 10-MHz band, and seven Societies to both 18 and 24 MHz. The other Societies had access to the 10-MHz band, and seven Societies to both 18 and 24 MHz. The other Societies were encouraged to take appropriate action to acquire usage of these bands and help to populate them.

After a discussion on the involvement of IARU in the forthcoming ITU Conference, preparations for the next WRC (expected in 1991), and the financing of these activities, QSL cards came into the discussion arena.

The Conference accepted a proposal from JARL to adopt the Manila-Conference standard QSL card size and layout, and JARL offered to coordinate an investigation into automatic sorting of cards. Papua New Guinea and Fiji papers on the use of the "honor system" when claiming awards drew much discussion. They argued that QSL cards were a hassle and an expense to rare DX and awards should be claimed by log entry only, as is done in New Zealand. ORARI countered this with the suggestion that QSL cards have many uses, including the promotion of the country and also of Society membership. The PNG/Fiji proposal was lost.

It was noted that with the entry of ARCOT (Tonga), there was only one society in Region III at present that was not a member of the Association.

The report of RAST (Thailand) caused several delegates to express disquiet at the mention of the use of several spot frequencies in the otherwise exclusive 2-meter amateur band for Volunteer Radio, a group of volunteers assisting the police by reporting suspicious happenings. It was felt that this might put ideas into the heads of other administrations along similar lines.

An international model standard, setting down minimum standards for gaining a general amateur license was proposed by NZART and JARL. In many countries that are newcomers to amateur radio, the administrations were often at a loss to set standards and appealed to the amateurs themselves. Therefore the model standard would be a help to these administrations. RSGB expressed the feeling that the proposal should not result in relaxing thestandards. The proposal was adopted.

From this, the concept of a worldwide common amateur license was raised. The effort of the European Societies toward this was noted and encouraged. ORARI commented that while they supported the idea, they could not see it happening in Indonesia in the forseeable future. The formulation of a special study group to investigate legislation that had bearing on amateur radio was suggested and set up, and the proposal passed.

Papua New Guinea's second paper highlighted the abuse of obtaining special prefixes, especially for non-radio events. A proposal to limit the use of special prefixes to national, international, and/or amateur-radio events of outstanding nature was accepted.

Four papers related to the subject of amateur satellites. JARL described progress on JAZ-1, whose launch has now been delayed until August, 1986. The first satellite's construction and testing has been completed and the second is undergoing testing now. The project is expected to cost $US1.6 million. Another JARL paper suggested that IARU coordinate all future satellite programs with ITU and satellite organizations.

The WIA expressed concern over the lack of information on progress of the various projects, on planned launches, and on frequency implications. Working Group 4 was formed to decide any action the Conference needed to take on these matters.

The final subject was the promotion of amateur radio in the developing countries. An NZART suggestion that IARU develop a simple transceiver for the use of these countries was immediately responded to by the Japanese. They showed the Conference a kitset transceiver that produced five Watts output on 15 meters, costing about $US60. NZART commented that, especially in the Pacific Islands, the most desperate need was for training and materials for training, at the very basic level, e.g., tools, books, and expertise. CRSA expressed appreciation for the supportive comments and the reception of their paper by the Conference. Working Group 5 was set up to identify appropriate means to encourage and promote amateur radio in developing countries, and recommend what action should be taken by the Region III Association and its members.

Day three saw the various Working Groups meeting all morning. There was a problem caused by the fact that many members had been nominated for more than one working group, and only three of the six groups had finished by the time Conference recommenced at 1300 hours.

NZART presented the first of four papers dealing with Intruder Watches. They commented on the worldwide nature of the intruder problem and said that a major improvement would be to get all broadcast stations removed from the 40-meter band. Also the Conference was informed that one of the main things to come out of the Geneva Study Group was the confirmation by the International Frequency Registration Board (IFRB) that the IARU Monitoring Service can legitimately call on the IFRB to monitor intruders on our bands.

CSRA noted that Radio Beijing was a major offender in the 40-meter band, and they suffered from this as well. They commented that there were historical reasons among others for this problem and expressed a desire to work towards fixing it. ORARI also reported discussions with their authorities to clear Javanese broadcast stations from 40 meters, and also Indonesian CB interference.

Other items discussed before the Conference adjourned at 1500 to allow the Working Groups to continue their deliberations were that Region III adopt the IARU International Locator System (Maidenhead System) as soon as possible. The Amateur Radio Direction Finding Rules from Region I were considered, and the subject of direction-finding activities in China and Japan described by delegates from those countries.

The IARU Region II Award together with some minor changes to cater for the changes in Region III membership were explained by NZART, and Conference showed its appreciation to NZART for operating the Award for the Association. Emergency communications as outlined in the WARC 79 resolution number 640 were discussed, and the Conference adopted Region I Emergency Procedure "in principle" after some discussion.

At the start of day four, the meeting considered an International Study Group report on the aims and operation of the monitoring service and adopted its recommendations unanimously. A new Region III monitoring service coordinator is required now that Bob Knowles ZL1BAD has been appointed as world coordinator.

Working Group 1 considered band planning, and presented their final report to the Conference. It described band plans for all amateur bands from 7 to 1240 MHz, but due to insufficient information did not consider plans for the 160- and 80-meter bands. Another working group will decide on these before the 1988 Conference. The plan for the 10-meter band included shifting all 28-MHz beacons to the band 28.190–28.200 by 1990. The Group made no special provision for packet radio but recommended that it be allowed in both the phone and RTTY parts of the bands.

Working Group 4 considered the Satellite Service and recommended that all Societies should provide support and funding for all satellite projects; that all frequency-planning matters for satellites be coordinated by IARU, and that the Amateur Satellite Service be represented solely by IARU at ITU Conferences.

Working Group 5—assistance to developing countries—decided the best way to arrange this program would be to ask all Societies what assistance they needed and what type of assistance they could provide.

Six papers relating to the International Beacon Project were considered, and then the Conference decided to adopt the NZART paper which called on the Administrative Council to provide all societies with information on the reporting procedure, to disseminate up-to-date beacon-status information, to review the 28-MHz project, and to provide a beacon kit to developing countries, and coordinate the publicity of the projects.

Contests were next on the agenda, and the Conference considered the adoption of preferred segments of the bands for contest operation as recommended by Region I. It was resolved that a working group consisting of representatives of JARL, WIA, NZART, and ORARI be set up to correspond and recommend on any preferred segments considered desirable.

The Conference proclaimed June 17 to be World QRP Activity Day, to encourage low-power activity—their decision was based on a Region I idea. The Conference also adopted an Administrative Council resolution to establish a World Radio Amateur Day intended to publicize amateur radio universally.

Some aspects of EME operation, packet radio, AMTOR, and RTTY standards, and the growing number of "unattended amateur stations" were then discussed.

A paper on problems resulting from some DXpeditions due to the behavior on air of some of the stations participating was presented, and after much discussion, accepted. ORARI commented that the DXpedition operator was in the best position to deal with this problem, and that IARU was not in any real position to be able to police this sort of thing.

Moving on to the preservations of standards of amateur-radio operation, recommendations by NZART noted the misuse of amateur radio by pirates and others, and emphasized the need to follow the spirit of the ITY Radio Regulations. The President of IARU

commented that, strictly speaking, policing this sort of thing was the responsibility of individual member societies. ORARI replied that they accepted this, but that recommendations by an international body were a very useful lever to help them initiate action in their own country. After considerable rewording to fine tune the meaning, the recommendations were adopted.

Day five commenced far too early for some of the delegates—Saturday night was the social highlight of the Conference, when all delegates relaxed and enjoyed an evening's entertainment, wining and dining, hosted by NZART, when the guests were introduced to some aspects of the Maori culture. The first item was the report of Working Group 2 looking at IARU participation in ITU Conferences. They considered appropriate representation at some designated Conferences, and accepted Councils' goals for the next general WARC. They also recommended continuing participation at CCIR activities, especially Study Group 8.

Working Group 3 presented a 30-page report dealing with changes to the Constitution and By-Laws. In considering this important subject, the meeting studied a large number of changes recommended by the study group. NZART moved the adoption of the proposed changes as recommendations to IARU, and this was passed.

Finances were next for discussion, and as is usual with money matters, there was considerable discussion back and forth, but the recommendations of the Financial Subcommittee were eventually passed almost as presented. NZART proposed the appointment of a regional coordinator for the study of Sporadic-E propagation on six meters, as had been done in Region I, and to recommend that Region II do likewise, to form a worldwide study on the subject. This proposal was adopted unanimously.

NZART presented a paper describing the history of the non-Morse license since its inception in 1963, and the benefits derived from it. It recommended the concept to other Societies as a way to encourage amateur radio. The paper was accepted.

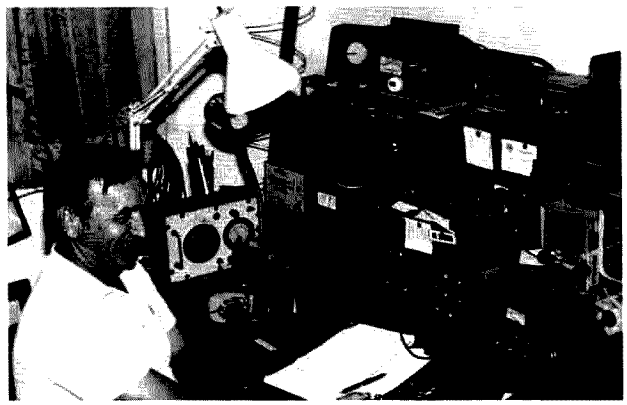
WIA proposed that US be recommended as the preferred mode for sideband operation on all bands. After a lot of fiddling with the wording of the proposal, WIA withdrew it.

There were five nominations for the positions of director for the next three years: Keigo Komuro JA1KAB, Michael Owen VK3KI, D. D. Devan 9M2DD, David Rankin 9V1RH, and Fred Johnson ZL2AMJ. No voting was necessary, and the appointment of David Rankin as Chairman was confirmed.

WIA paid tribute to the work of Arthur Godfrey ZL1HV as a delegate and Director of Region III. In reply, Arthur dwelt on the need for adequate turnover in Association representatives, to get new blood in and avoid inbreeding. Masayoshi Fujioka JM1UXU was elected for a second term as secretary, unopposed. WIA drew the Conference's attention to the extensive backup support for the Secretary provided by JARL, for which the Association is very grateful.

Five invitations to host the next Region III Conference were received from KARL, WIA, PARA, ORARI, and BARL. After a secret vote, it was declared that the invitation from KARL was accepted and that the next Conference would be held in Seoul, Korea, around late October, 1988.

While the delegates were busily engaged at the Conference sessions each day, the ladies who accompanied them were well cared for by the ladies of the host society. Among the activities the ladies visited were tours of an orchard, a potter, a wool shed display, botanical gardens, various scenic drives, shopping trips in Auckland, where the OM's hard earned cash was no doubt well spent on souvenirs, and in the evenings there were receptions hosted by IARU, ARRL, JARL, and NZART.



And so ended the 6th Region III Association Conference, after a very busy five days. The delegates bid each other fond farewell and left for their respective destinations, to come together formally in three years time for the 7th Region III Conference.

PHILIPPINES

Leo M. Almazon WA6LOS/DU2
10098 Knight Drive
San Diego CA 92126

Hello, everyone! Now that I have more free time, you probably will see more articles about the state of hamming here in DU-land. I would like to congratulate the officers and members of PARA, the Philippine Amateur Radio Association, for its 52nd anniversary.

Mel Bednar K6LPN/DU2, current trustee of the Central Luzon Amateur Radio Club (CLARC).

Engr. H. San Juan of the National Telecommunications Commission said that his office is set to carry out Memorandum Circular No. 14-11-82—guidelines and procedures of the Revised Amateur Radio Regulations.

Engr. San Juan has said that proper use of callsigns (DU for Class As, DV for Class Bs, and DW for the Class Cs), their proper frequency allocations and, of course, the "jammers," or illegals using the amateur frequencies for their personal use, will be monitored! Under the new Radio Regulations, violation of any of the provisions of the new laws will be punished by a fine of not more than 2,000 pesos (about $100), or by imprisonment of not more than two years for each offense, or both, at the discretion of the court.

If you have followed my other articles in this column you probably have heard me mention CLARC, the Central Luzon Amateur Radio Club which is a unique ham club in DU-land, in that its members consist of local hams and American hams mostly working at Clark Air Force Base in nearby Angeles City, located about 56 miles north of Manila. The base is one of the largest US airbases outside the United States. One of the club's founding members, Pete Bargas DU1AK, is the only American ham who is legally authorized to use a DU callsign. Pete is one of the OT hams in the country; his hamming in DU-land dates back to the 1930s, when he used to be KA1AK. The Philippines was one of our former territories and was assigned with a KA prefix.

The current president of CLARC is Dr. Ronald Yuson DW2DX. I have known Ronald since his medical internship days. I used to go with him in his rounds in the hospital ward at Central Luzon General Hospital, and also during his duties in the emergency ward. This is where I saw, firsthand, emergency medicine and radio communications hand-in-hand.

Most ambulances are not equipped with radios, as in the States. It is only through amateur radio that quick arrivals of help and diagnosis are made. But unfortunately this happens only when there is a big typhoon or during the Easter holiday when there is a lot of traffic and the government, together with other civic-action groups, invites local hams to help provide much needed communications for emergencies.

DW2DX has been instrumental in a lot of civic-action duties, doubling both as a communicator and a physician when needed. Even though the issue of his callsign came two years after passing his test, DW2DX never got discouraged and found time to be active in ham radio despite raising two harmonics and his medical duties. The local hams and would-be hams should take note and not get discouraged. License examinations and processing do take time, but rest assured PARA and some other well-connected individuals are trying to rectify this pressing problem.

Feb. 16, 1985, was a day to be remembered by the local hams. It was the day of the Hamvention 85. It was held at Camp Concepcion Gonzalez in Novaliches, Metro Manila. It was hosted by several clubs from District 1, and also by the Citizens Band group together

with the Philippine Girl Scouts. The guest speaker was none other than National Telecommunications Commissioner General Ceferino Carreon. There were swap meets, flea markets, a CW contest, and DX contests.

But the significant difference in this year's event was the presence of many OTs mingling with other local contemporary radio enthusiasts. I guess the event's theme, "Unity for Radio," was appropriately embossed in everyone's mind during the whole festivity. More on the Hamvention next time, since there were a lot of activities to be mentioned and lots of film still to be developed!

Speaking of amateur-radio themes, one that comes to mind is this one. "International Friendship and cooperation of all peoples in Asia through Amateur Radio." This, folks, is the theme of the SEANET, the South East Asia Net you can hear operating on 14.320 MHz. The last SEANET convention was held November 16 through 18 at the Eastern and Orient Hotel in Penang, Malaysia.

This net started out as a friendly gathering of Southeast Asian hams on 20 meters every evening but grew to include all other DX stations who regularly check in. Net controllers are VK2MA from Sidney, Tom VS6CT from Hong Kong, and Dr. Ed DU7EG from DU-land. The convention is an annual event and is hosted by the different original Southeast Asian member countries. Last year's SEANET ham attendees were from the Philippines, Japan, India, Thailand, the United States, Singapore, Indonesia, Australia, and Brunei.

The plan for the next SEANET convention is to hold it right here in DU-land. The organizers have eyed beautiful Cebu City as the host city. Cebu is about 600 miles south of Manila, and many domestic flights are available to Cebu City from Manila Domestic Airport. The tentative dates are November 22 through 24, and it is hoped that DU hams will be directly involved in this 15th SEANET convention.

Well, once again we will say 73 for now and hope to bring you another column soon and update you with the Hamvention 85 here in DU-land—and also share with you some pictures of the event. Good luck and happy DXing.

DEALER DIRECTORY

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, land-mobile. **Fontana Electronics, 8628 Sierra Ave., Fontana, CA 92335, 822-7710.**

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1775A S. Winchester Blvd., Campbell CA 95008, 370-6665.**

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Kenwood, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle, DE 19720, 328-7728.**

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood. Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delata protectors. ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL-COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton, MA 01460, 486-3400/3040.**

Derry NH

Serving the ham community with new and used equipment. We stock and service most major lines: AEA, Astron, B&W, Cushcraft, Encomm, Hy-Gain, Hustler, ICOM, Kenwood, KLM, Larsen, Mirage, Mosley; books, rotors, cable and connectors. Business hours Mon.-Sat. 10-5, Thursday 10-9. Closed Sun./Holidays. **Rivendell Electronics, 8 Londonderry Road, Derry, NH 03038, 434-5371.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the June '86 issue must be in our hands by April 1st. Mail to *73* Magazine, WGE Center, Peterborough, NH 03458. ATTN: Hope Currier.

TELEGRAPHY AND STUFF

As regular "Fun!" readers know, I don't think that a knowledge of the Morse code should be required of prospective radio amateurs.

Call me a radical, call me crazy, but I just don't see how an ability to use an obsolete form of binary communications is going to save our hobby.

Anyway, enough of that. It's time for a surprise. I actually love the code. I don't happen to think the Morse code should be crammed down the throats of newcomers, but I'm all in favor of using it on the air. Sending CW is fun, relaxing, and a great way to relive the historic past of radio. I like it. Call me duplicitous.

Last Christmas, my kid brother, WB2LWJ, gave me a great gift—a Vibroplex semi-automatic keyer (a.k.a.—"bug"). Best of all, it was a presentation model, the type with the gold-plated base.

What a Christmas! I was a kid again, prowling 20 meters for DX, engaging old friends in seemingly endless QSOs, and ditting and dahing away until my ears fairly rang with the sweet music of CW.

My brother tells me he got the keyer at Barry Electronics, a New York ham fixture and landmark. With Harrisons' death, Heathkit gone from the city, "radio row" replaced by the World Trade Center, and Lafayette now into discount VCRs and stereos instead of TR-4Cs and grounding rods, Barry's is the last vestige of a time when the Big Apple was the radio (both professional and amateur) capital of the world.

Anyway, when my brother showed up at Barry's to purchase the keyer, the folks behind the counter thought that 'LWJ was Mr. Fun! They believed that his denials were merely a form of KI2U modesty. How wrong they were. The real Mr. Fun!, although somewhat older, is far better looking than his brother. And KI2U is never modest about anything, except perhaps his ability to run a repeater.

But that's another story. For now, let's stick to CW and its ancestors.

ELEMENT 1
MULTIPLE CHOICE

1) Approximately how many parts are there to a typical Vibroplex bug?
   1) 10
   2) 20
   3) 50
   4) 100

2) Samuel Finley Breese Morse was born in:
   1) 1791
   2) 1815
   3) 1830
   4) 1840

3) Thomas Edison in 1874 created "quadruplex," which allowed a telegraph transmission of:
   1) one message in four directions
   2) two messages in two directions
   3) four messages in one direction
   4) one message in two directions

4) The early submarine telegraph indicated "dits" and "dahs" with the aid of:
   1) a sounder
   2) a deflecting needle
   3) a lamp
   4) an audio oscillator

5) In addition to his inventions, Morse is also particularly well known for having been:
   1) a painter of miniatures
   2) an acrobat
   3) a skilled violinist
   4) an author of romance novels

ELEMENT 2
TRUE-FALSE

	True	False
1) The spark transmitter of Hiram Percy Maxim W1AW was named "Ol' Reliable."	_____	_____
2) Morse's first telegraph link was between Baltimore and Philadelphia.	_____	_____
3) Morse's original telegraph receiver emitted a 10-kHz audio tone.	_____	_____
4) Morse was the first president of the National Academy of Design.	_____	_____
5) At one point, Morse held a chair in Natural Science at Yale.	_____	_____
6) Morse died in 1891.	_____	_____
7) Radio Telegraphy was introduced by Marconi in 1897.	_____	_____
8) Morse added an audio buzzer to his telegraph receiver in 1855.	_____	_____
9) The Vibroplex bug was invented by Horace G. Martin.	_____	_____
10) The first telegraph keys had no knob.	_____	_____

ELEMENT 3
SCRAMBLED WORDS

Unscramble these words relating to telegraphy:

praghyleet	romse	rekye	notedesi	gub
sift	pocy	eky	doce	idt

ELEMENT 4
FILL IN THE BLANK

1) _____ installed the first railway telegraph system in England in 1837.
2) Samuel F. B. Morse was born in the town of _____, _____.
3) First telegraph message: "What hath God _____"
4) The Morse code's "dit" and "dah" elements are separated by an interval that has the duration of _____ dit(s).
5) The "dah" has a duration equal to _____ dit(s).

THE ANSWERS

Element 1:
1—3, 2—1, 3—2, 4—2, 5—1.
Element 2:
1—False, "Old Betsy"
2—False, Between Baltimore and Washington
3—False, It printed "dits" and "dahs" on a slip of paper.
4—True, From 1826 to 1845, after which telegraphy increasingly occupied his time.
5—True, He was an instructor at New York University, located just a little north of Barry's.
6—False, 1872
7—True, And it sort of caught on.
8—False, Morse never did apply a buzzer or other sounding device to his invention. That honor went to a fellow named Alfred Vail.
9—True, Who else? Martin was a turn of the century telegraph operator who invented the bug to relieve arm strain. Many experienced ops thought the device a "sissy key," however. It took a while to catch on.
10—True, No "sissy key" ops back then.
Element 3:
Reading from left to right: telegraphy, Morse, keyer, sidetone, bug, fist, copy, key, code, dit
Element 4:
1—Sir Charles Wheatstone
2—Charleston MA
3—wrought
4—one
5—three

SCORING

Element 1:
Five points for each correct answer
Element 2:
Two and one-half points for each correct answer
Element 3:
Two and one-half points for each correct answer
Element 4:
Five points for each correct answer.

How did you do?

1–20 points—Novice
21–40 points—Technician
41–60 points—General
61–80 points—Advanced
81–100 points—Amateur Extra

NEVER SAY DIE

Along about 33 years ago I started a column in *CQ* on RTTY. Yep, I was into digital communications that long ago, for those of you who thought digital was something new. I thought I'd mention that before I tell you I'm looking for some really active hams to do some columns for *73*.

Columns on some special ham interest usually start out like gangbusters, but after a while the columnist usually runs out of steam. As an ex-columnist I know all about that side of the street.

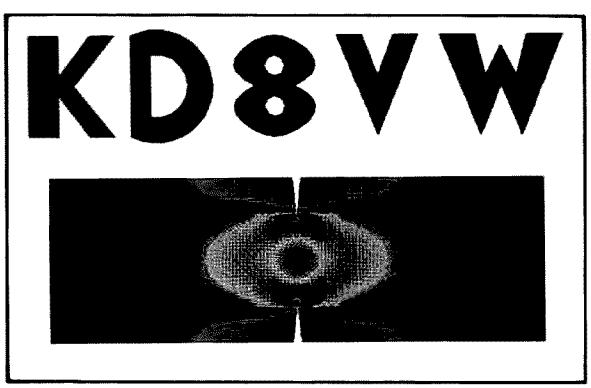
So what I'd like to do is have the best of both worlds—cake and eat it too division. I'd like to see some experts tackle subjects that I know can be very interesting—such as RTTY, SSTV, packet radio, repeaters, UHF, antennas, DXing, ham clubs, mobile, contests, certificate hunting, QRP, facsimile, traffic handling, nets, home construction, and so on. I'm talking about having short, interesting columns—some monthly, some bimonthly—for each special ham interest.

This is the catch: I'll be asking you to vote every month on which columns you enjoy and which you find boring. If a column doesn't make the grade with you, it's out.

Since thousands of hams are interested in every one of the facets of our hobby I mentioned, a columnist should be able to make every column a winner. If I'm able to find someone to report on your particular interest and you allow the column to become boring, you'll lose it. You'll also lose the opportunity for getting a few thousand more hams involved with your special interest—and the opportunity to attract manufacturers to your interest.

If you would like to try out for a column, and for fame and fortune (well, fame, anyway), the route to stardom is simple. First drop me a line explaining what special ham interest you want to write about. Then tell me about your background and why you are the ideal person to tackle this. Third, I'd like to have an idea of your resources: what you've accomplished, who you know, what ham manufacturers may help you, and so on. Fourth, I need to see a couple of sample columns. I warn you, I'm going to read them lying in bed, dead tired. Either you keep me awake in a fever pitch of excitement and get the contract, or I'll save your columns for when I have insomnia.

I do expect you to have a working knowledge of grammar and to either own a dictionary (which you use) or have a spelling checker in your word processor. Once we get started I'll expect to get your material well before deadlines—preferably via a floppy disk or, better, via modem. We're totally automated here, so we don't re-keyboard stuff any more. It all comes in from our writers' computers.



The columns don't pay enough for you to do all that work for the money. We pay around $100 or so, enough to buy a little extra ham gear. The columns should be fairly short, maybe two or three double-spaced printout pages. We're not looking for the Great American Novel; we want to get excited about amateur radio.

One extra spiff, in case you haven't thought about it. Surveys of past authors have shown that being published in a technical journal such as *73* can help substantially when you are looking for a raise or a better job. In general, the rule is that your salary will go up about $1,000 per year for each article you have published. I'll bet it never occurred to you why so many hams were writing articles for ham magazines. There is more than their love of the hobby involved, though that doesn't hurt.

TNS = THE NEW SIX?

Unless you've been holed up in the back of your ham shack, cut off from the real world by an

QRX . . .

EDITED BY PERRY DONHAM KW1O

But, Nooo . . .

SOME PEOPLE OUT THERE apparently don't appreciate all the hard work put in by amateur volunteers to ensure continuous communications during an emergency. In a letter to the Cellular Telecommunications Industry Association, **Martin Hertz** (!) of the **Communications Attorney Service**(founded by Richard Cooper) attempted to prove "that the American Radio Relay League and its ham-radio followers are trying to undermine the legitimate commercial radio interests." Attached to the letter was a copy of a story (from *WorldRadio*) which chronicled the exploits of a group of hams who provided a large hospital with emergency communications after the facility's telephones went dead. Hertz believes that this type of assistance is contrary to Part 97 of the FCC Rules and Regulations and points out that, "We in the CAS cannot believe that those who organized [this] radio fiasco could not locate hundreds of thousands of Part 95 licensed Citizens Radio operators to fulfill this duty legally." Finally, the CAS asked the CTIA for "support in neutralizing both the American Radio Relay League and its followers." The Old Man would have applied liberal doses of Wouff Hong to these guys!

Kiri On

T32 EASTERN KIRIBATI will be active during this year's *CQ* WPX SSB test. **Junichi Tanaka JH4RHF** reports that a group of four will make the trip; operation will begin on March 26 and continue through April 2. Look for the DXpedition on all bands, CW and SSB, before the contest. QSLs go to Junichi Tanaka JH4RHF, 146 Kotobuki, Hattori, Toyonaka, Osaka 561, Japan.

Money Matters

TWENTY-ONE SCHOLARSHIPS are available for college-bound hams for the 1986–87 academic year. The scholarships, administered through the **Foundation for Amateur Radio (FAR)**, are sponsored by the Quarter Century Wireless Association, the Dade (Florida) Radio Club, the Baltimore Amateur Radio Club, the Department of State Amateur Radio Club, Radio Club of America, the Richard G. Chichester memorial, the Young Ladies' Radio League, the Edmund Redington Memorial, the Amateur Radio News Service, and the Columbia (Maryland) Amateur Radio Association. Awards range from $350 to $900. Applications and information are available from FAR Scholarships, 6903 Rhode Island Ave., College Park MD 20740—your request must be postmarked prior to May 31, 1986.

Carib Hams QSY

CARIBBEAN AMATEURS may now use voice communications on 7.075–7.100 MHz. The new rule, which went into effect at the end of February, allows hams with General, Advanced, or Extra tickets to use the new segment. The reason for the change is the heavy broadcast interference present from 7.1–7.3 MHz, which renders the band nearly useless during the evening hours. **David Novoa** started the ball rolling back in 1984 with a petition that asked for parity with other Caribbean nations. Most emergency and service activity in the area is located below 7.1 MHz, and, under the old rule, U.S. amateurs couldn't participate in these nets. The FCC felt that the number of potential users of the new segment was so small that additional interference to non-voice communication in the segment would be minimal.

Atari Trick

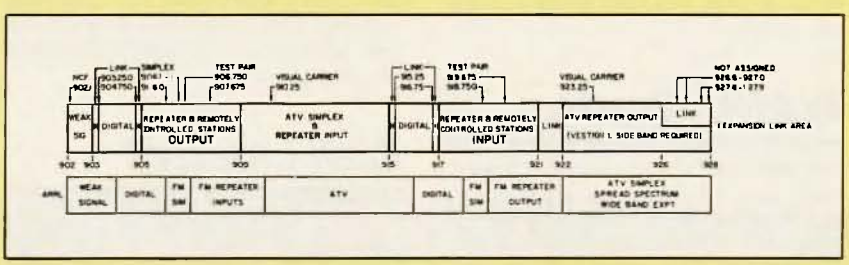
WOODY GRIGGS WA4NZO has come up with a simple trick for Atari 800XL owners who would like to use Kantronics' Hamsoft RTTY program:

1. Turn your 800XL and disk drives off.
2. Turn on the disk drive.
3. Place a "Translator" disk in the drive.
4. Turn on the computer—do *not* hold down the option key.
5. Once the machine has booted, replace the Translator disk with a DOS 2.0 disk (there should be no auto-run program present).
6. (Here's the tricky bit!) *Carefully* plug the Hamsoft cartridge into the 800XL. If you see garbage on the screen, don't panic!
7. Hit the reset button. Hamsoft is now ready to use.

Planned Band

A NEW BAND PLAN for 902–928 MHz has been adopted by the **Southern California Repeater and Remote Base Association (SCRRBA)**. Representatives of the major users of the new 33-cm band met in Hollywood to discuss interference from non-amateur radio services, and to debate an equitable distribution of the spectrum. The SCRRBA document parallels the ARRL's interim band plan, making certain adjustments for local operating conditions. If you are interested in how the Association developed its proposal, contact it at PO Box 5967, Pasadena CA 91107.

QSL Via . . .



AND NOW a word from **Richard Breckinridge WA9BXB**: "Please be advised that I am now the QSL manager for **Ian Williams VK3MO**." Richard's address is 3827 Kemman Ave., Brookfield IL 60513.

DARA Dollars

TWO $1,000 SCHOLARSHIPS are available from the **Dayton Amateur Radio Association** (the Hamvention people). Any licensed amateur graduating from high school in 1986 is eligible, and there are no restrictions on the student's planned course of study. To emphasize the importance of clubs to amateur radio, DARA asks that each application be accompanied by the recommendation of a local club officer. (Don't worry if you have no club nearby; just have your form signed by a licensed ham.) Entries must be postmarked no later than May 15, 1986, and the winners will be announced in early June. You can get information and applications by writing to DARA, Box 44, Dayton OH 45401. Attn: Scholarship Committee.

Sat Shoot Set

A NEW OSCAR SATELLITE is scheduled to launch this fall aboard a European Space Agency Arienne 4 booster. The Phase 3C bird will carry four transponders for modes B, J/L, L, and S. Mode B uses the familiar 435-MHz

SCRBBA's band plan for 902–928 MHz (above); ARRL's interim band plan.

NEVER SAY DIE

from page 4

electronic ham senility wall, you're probably wondering whether you should cheer or holler bloody murder over the Don Stoner W6TNS proposition that we forever give up the top half of six meters.

Now I have no objection to Don getting rich as Croesus with his new idea. Heck, it might even help a bunch of people get rich—and that's nice too. But there's that niggling question that frankly niggled enough to wake me up at 2 am and get me out of bed to write this. I really hate to be niggled out of bed.

Don's proposal, in case you missed it, calls for us to donate the 52–54 MHz half of six meters for use as a non-ham digital message band. His idea is that there are zillions of computer hobbyists out there who might jump at the opportunity to network over the air instead of by telephone. Moot. I won't go into a long technical explanation of how Don proposes this be done so as to keep TVI to a minimum, so let's just not worry about that part of it. The main question is this: Do we hams need that unused half of six meters for anything anymore?

My first reaction is to admit that no, it sure doesn't look as if we'd be giving up much. But as I think it through I realize there are enough points to consider so I could effectively argue—heatedly, of course—either side of the proposition.

First, on the pro side, I have to admit, as a pro, that the frequencies in question are flat out not being used enough to honestly offer any argument against Stoner. Even more, never in the past have we ever really used or even needed these two MHz for much. To take that one more step—I don't even see any potential use ahead for the frequencies.

To make it even more binding, I remember that we have a dying hobby where we're seeing less and less innovation—even if there was a new technology ahead that might need to use these frequencies, I'm not sure we have enough pioneers to make it happen.

Most of us are so tied up with nightly 75m rag-chewing nets, exacerbating the 20m pile-ups on minor DX, or telling people at great length where we are in our car over a 2m repeater that the top half of six meters is as remote as our going on a DXpedition to Sarawak.

Hey, that isn't a bad idea—remind me to develop that one for you later.

Okay, if we've never had any use for the band—if we're not using it now—and if we don't even have the faintest hint of any future use for the band, why not shut up and donate it to the cause of making Stoner rich? What was it that got me out of bed to write this morning?

History is what done it. Let's go back and take a look at six meters and its history. One of the benefits of being as old as I am is that I'm a living connection to the past. Most of the time this is more of a bore than a benefit, since few younger people want to hear about "how it was." When I start talking about nickel ice cream cones their eyes glaze over.

The six meter band came to us after WWII—I think we got it along in 1946 or so. Before The War we had a five meter band—54–60 Mc. 50–54 Mc was the FM radio band—mostly used by the Major Armstrong experimental FM station in Alpine NJ. Was it W2XEL? After WWII that ended up as TV channel 1 for a while, with 54–60 Mc as channel 2.

This was sorted out by moving FM to 88–108 MHz and channel 1 being changed to the six meter ham band. I was one of the early explorers on six. I was living in Brooklyn at the time and I was the only ham in New York City on six meters. Unlike the old pre-war five meter band, where what little activity there was was made up of little one-tube modulated oscillators, six meters started right out with crystal-controlled rigs.

I could tell exactly who was on the air in a few seconds just by the frequency of the carrier. I had an accurate frequency standard—surplus General Radio LR-1 job—a 94-tube three-foot high kluge. So when I'd hear a carrier I'd just crank the LR-1 until I'd get a beat note and read the call letters off a frequency chart I'd made.

It might be Frank W2AMJ down in New Jersey or Ed Tilton W1HDQ, the VHF editor of *QST* way up in Connecticut. There were just a few of us, so we all knew each other.

I remember a local Brooklyn SWL coming over on his bicycle to visit. He'd heard me talking on channel 1 of his TV set—yep, some of the early TVs had channel 1 on 'em. Years later he got involved with computers as a hobby and opened a successful computer store in Westchester—advertised in my computer magazines.

You know, come to think of it, this early work on 6m was what got me into publishing. In order to keep track of when 6m was opening for DX contacts a number of us put beacon transmitters on 50.1 MHz. I rigged up a code disk with a microswitch to key my 6m rig and let 'er run when I wasn't making contacts.

Perry Ferrell organized a government-sponsored research project to investigate 6m propagation, so I naturally participated with my beacon. Later, when he became the editor of *CQ*, I kept in touch with him, explaining about my work with digital communications and RTTY. This lead to my writing a column in *CQ*. Then, when I helped Perry get a better job as the first editor of *Popular Electronics*, I fell heir to his old job at *CQ*. . . much to my surprise.

Perry edited Poptronics for years—then, in one of Ziff-Davis's larger publishing miscalculations, he was canned. Perry and his wife, Jeanne Gillespie formed Gilfer Associates and sold SWL equipment and information by mail. Perry died a few years ago and Jeanne is still running the business. Say hello to her at Dayton. Better yet, look over her SWL equipment—you might just want a Sony 2002. I've got one and use it every day for time ticks, shortwave, and FM.

Unlike six meters, two was enormously busy in the late 40s. It was a time of change on two, with a few broad old modulated oscillators and an increasing number of crystal-controlled—stabilized, they were called—rigs. I was one of the first to get on 2m with an SCR-522—*the* first, I think.

I remember, when 2m first opened, having a ball with a pair of 6C4 tubes in a grid-modulated long-line oscillator in the trunk of my '40 Ford. The receiver was a super-regen. W2NYC and I would drive to the highest hill in Brooklyn and work over to Staten Island and New Jersey with it.

The next big event was when a ham, George Sterling W1AE, became the Chairman of the FCC. This was when we got our Novice Class license. Novices were permitted voice communications—145–147 MHz. The League was in the hands of an arrogant, foul-mouthed general manager, so the FCC wasn't even talking with them. The ARRL fought the new license class, but were no match for the FCC Chairman. The League has never really accepted Novices as actual hams.

Eventually the FCC discovered that Novices were infinitely more interested in voice than CW communications, with most of 'em migrating quickly to 2m. Unfortunately they then lived out their two-year license on 2m and never made it to General. So they killed the 2m Novice band and brought us the Technician Class license—which the ARRL also fought and has hated ever since. Techs got to use the old Novice 145–147 MHz band—and the six meter band.

Techs took to 6m with a vengeance. Six was hot during the sunspot highs, opening often to Europe and around the country. I worked all over Europe on six meters. When six was hot it would be jammed with stations—almost like CB. Can you imagine tuning from 50.1 on up to above 51.0 MHz and not finding a clear spot to work? There were even a few explorers up in the 51–52 MHz part of the band!

Six stayed a hotbed of Tech activity up until 2m FM and repeaters came along. That got started for real in 1969. By 1973, six was almost deserted. These days you hear an occasional ghost signal on six. Not much doing there. Back in 1972 I cross-banded my 2m repeater to six. That was fun—with occasional contacts out in Ohio, Tennessee or Florida when the band opened.

Six meters never really recovered from the 2m repeater explosion, so it sits there, waiting for some hoped-for technical development that might bring interest to it again. Even the sunspot highs won't do much for it because 6m is mostly an American band. It's used for other services in Europe these days.

Now, to get to a con point. And no remarks about me being a con-man. Up until 2m FM and repeaters came along the top 2 MHz of 2m was almost totally unused. The General Class licensees tended to operate

from 144–144.5 MHz and the Techs from 145–145.3 MHz.

Oh, let me tell a story. Ed Tilton, W1HDQ, got all bent out of shape over some local 2m hams who kept interfering with his DXing on the low end of the band. Ed had a big antenna and plenty of power, so he had a Big Signal. I had a Big Signal from Brooklyn too—with my 16-element beam and a kilowatt. Well, Ed couldn't get a couple of lids to move up the band and let him DX so he got the League to petition the FCC to set aside 100 kHz for CW-only.

Believing that we would do better to reason with lids than to legislate band segments like that, I countered with the proposal to put the CW band at the top end of 2m—147.9 to 148.0. The FCC did just that, to my great delight. Ed had been bragging that he was going to get those damned lids off his frequency. Well, the new CW band got zero use, of course, and eventually it was shifted to the low end, where it's been a royal pain ever since.

Getting back to two meters. There was a strong push by *CQ Magazine* to take the unused 2 MHz—146–148 MHz—and make a CB band out of it. After all, we hams weren't using it and would never need it for anything, so why not? I fought the proposal with *73 Magazine*, and it was defeated. If we'd gone along with the *CQ Magazine* idea that an unused ham band would probably never be needed, we could easily have lost the most used ham band we have today.

So I worry. I see us losing frequencies at every turn. We just lost the low ends of the 420–450 MHz and 1215–1300 MHz bands. No, we're not using these much right now, but I can see some real solid potential for their need—particularly if we ever manage to get amateur radio growing again by getting some youngsters into our hobby.

Will some technical development come along to make us regret donating half of our now dormant six meter band to Stoner's plan? Maybe, maybe not. We can't tell about that any more than we could foresee needing frequencies for repeaters. We sure lucked out on that one.

Now, let's suppose that we do somehow manage to get amateur radio growing—with thousands of ham clubs in schools again the way it used to be before Incentive Licensing wasted them. Let's suppose, even further, that we're able to put together a national digital communications network where any of us will be able to type a message (or speak it into a typer) and have it automatically relayed anywhere in the country. Will we be able to do this without having an unused resource of ham frequencies for this new service?

I can see a network of local digital repeaters—maybe working on the packet principle—tied through satellite links to the entire world. Would we need that 2 MHz of six for this or could we get by with what we have to spare on 2m?

Oh, writing of digital, within a couple years I expect we'll be seeing digital television starting to take over. Our 8mm video tape will go digital, making it possible to relay video any number of times anywhere without even the slightest loss of picture.

Of course there is always the possibility—maybe even probability—that all we will ever need for amateur radio are our old bands where us old timers can hang out and ragchew until we die.

Writing of dying, I've noticed that what used to be a small box in QST—Silent Keys—these days has taken on more the dimensions of a special segment of the magazine. I go through it each month, marking the old timers I've known personally—remembering them. An even better exercise is to join the QCWA and go through their newsletter, which dwells even more on the swelling tide of dear departeds. Probably mostly smokers, eh?

Well, what do YOU think about our giving six meters to Stoner? Of course I'm exaggerating—if Stoner gets his plan accepted we'll see a bunch of firms—Japanese firms, of course—making equipment for the new band. If many people get interested in the new band it could turn into a new industry, complete with a Wayne Green magazine. And think of the potential for selling high powered amplifiers for a one-Watt limited band! Zowie! Shades of CB.

Other than that I like Stoner's idea. I'm not at all convinced the new service would attract many users, but if it did it could be fun.

The millions of home computers do present a challenge. If the people with these could be enticed to network them over the air, it could be a big industry. Surveys have shown these computer owners to be interested in radio communications, but to be so put off over having to learn the Morse Code to get a license as to be unavailable as potential hams.

Any thoughts?

MAKING MONEY

When you think about the enormous shortage of electronic technicians in the United States, you realize that there's lots of opportunities out there for anyone with entrepreneurial leanings to make money. It's so easy for any ham who is really interested to make money that I get a bit annoyed when I hear hams complaining about being short of money. It's out there in gobs.

For instance, maybe 15 years ago I recommended that hams interested in making a few extra bucks could do worse than get into selling alarm systems for homes and commercial buildings. I heard from quite a number of hams who took my editorial seriously and went into the business part time to start, but soon found it far more remunerative than their old job. Many did very well.

Well, that same business is still out there, waiting for anyone with some gumption to get into the business. Today only 8.6% of private homes have alarm systems. You couldn't ask for an easier market!

You can sell and install alarms—all kinds.

LETTERS

WELCOME BACK

Congratulations on your return to being a great ham radio magazine. I subscribed to *73* for many years after it started publishing. Finally, it got so oversized that I couldn't find the time to read it. I dropped my subscription because I couldn't stand to wade through about 180 pages to find two or three articles I liked. I picked up the January issue on a newsstand, and I liked it.

Donald Burr AJ6X
Fresno CA

THE NOVICE DEBATE

I have read in past issues the pros and cons of Novice enhancement. Most of those against it are the ones that are afraid that frequencies might be taken away from them. I have yet to see a band that had barriers that kept higher classes from using Novice frequencies.

Come on, let's all grow up and start looking at the plus side of letting Novices use SSB on 10 meters. When was the last time you actually held a QSO on 10 meters, or heard it being used on a regular basis? Many hams would prefer to have the newer bands put in place of the 28-MHz positions on their bandswitch. Many don't even switch to it or listen to it. Of course this wouldn't open the band up because no one would be talking; everyone would be listening. But by allowing the Novice to use SSB on 10 meters, someone would be talking. With the power output allowed to Novices, they could easily talk 20–60 miles daily. This would not be another 11-meter band. I believe we could control ourselves enough to prevent that. Let's stop crying about what might be taken away, and start looking at the plus side:

1. Hams actually using a band (which would normally go unused) and monitoring it on a daily basis.

2. More chances for DX on 10 meters once other countries know we are using the band again.

3. More chances for Novices to get together and hold a conversation that doesn't take two hours to say how the weather is.

4. More Novices would band together and would be able to offer each other the assistance needed to upgrade.

Numbers 1 and 2 are important to all of us, but number 4 is important as well. It is a lot easier to upgrade to higher classes if you have someone to study with. I believe we would actually have an increase in hams upgrading above the Novice/Technician tickets.

John M. Lothridge WD4NQG
Tampa FL

John, you're probably right about the need to get Novices off CW and onto phone again—also the possibility for getting our many unused bands active by opening them to Novices. But I don't think you'll ever get the League to go along with you, and remember, they can get 1% of the clubs to totally swamp the FCC any time they want. Perhaps the FCC is easily swamped. With ten dead these days, Novices might bring it back to life. And then there's poor old six meters, even deader than ten. Two is pretty occupied, except on the low end—how about a Novice phone band from 144.–144.1? I think we've got a lot of room for Novices on 220 MHz. 432 is busy, at least in Los Angeles. 1250 is wide open—as are all the rest of the bands above that. But John, on #4, you're dreaming. Once Novices get phone privileges you'll never see them make the slightest attempt at going for a higher grade license. That's what we found when they were on 2m and there's no reason to believe you'll see it any different if we try it again.—Wayne.

FIND THE GOVERNOR

This is no doubt one of a great many letters you will receive from Texans correctly identifying Texas Governor Mark White as the man on the left and K5RC as the one in the middle of the "County Bounty" photo in "QRX" (January 1986).

An interesting issue. I enjoyed it.

R.B. Peebler W5KIW
Radio Officer, S.S. *Bay Ridge*

AN UNJUST ACCUSATION

In my four years as an amateur radio operator, I have never heard anything as disgraceful as a recent event on a Long Island NY 2m repeater.

Several stations involved in a round table were interrupted by another station who inserted his call between transmissions. When the breaking station was given the opportunity to speak, a majority of his signal was noise. A control operator then broke in and advised that the interrupting station was not listed in the callbook and was operating illegally.

After repositioning, the station called in again with a full-strength signal. At this point, the control op ordered the station to cease communications at once, saying if the station wished to use the repeater he would have to send a copy of his license for verification purposes. Later, the control op announced he had in fact overlooked the callsign in the book and apologized to the station.

Another station came on to criticize the control op for the manner in which he had handled the situation. The control op informed him he obviously did not have any idea how to operate a repeater. This know-it-all control op was responsible for emissions from the repeater and should have activated some function to prevent the outside station from getting into the machine. Besides, he also violated the rules by directing his transmission to a so-called unlicensed party.

Do you think a new ham would be very impressed with the hobby after having an experience like this? What about the ham who has been licensed 25 years and suddenly changes his callsign? Would that ham now be illegal since he is not yet listed in the book?

Hopefully the control op will use better practices in the future. I'm sure any ham would be just a bit more than angry if he or she was called an illegal operator!

Jeff Gornstein NJ2Q
Springfield NJ

Jeff, it sounds like your control op has a sure cure for a non-jammed repeater. But if that's the worst you've heard, you need to hear some tapes of L.A. repeaters. Hmmm, maybe there's a market for garbage like that—I may be missing an income source.—Wayne.

HELPFUL READERS

Needing a circuit for a Hallicrafter S40A receiver, I wrote to *73*'s "Ham Help" asking for same. I obtained a copy shortly after this request appeared.

I was both surprised and pleased in getting several more copies from other readers. Although I tried to reply to all, writing is difficult for me as I am badly vision-impaired.

It is gratifying to know that the spirit of cooperation and help from one ham to another is still as strong as it ever was. And through the good offices of *73* Magazine others may similarly be helped.

I wish to thank all those who have helped and offered to help me with this project.

Gerald Samkofsky N4ZB
Holiday FL

Gerald, all 73 readers are true-blue, we just won't settle for any other kind.—Wayne.

TURNING OFF TEENS?

In his letter in the January, 1986, issue, Mr. Vrenios came very close to the true cause of the increasing average age of amateurs. As he noticed, this is not a problem unique to amateur radio. The fact is, today's youth are less interested in model trains, stamp and coin collecting, photography and all hobby activities.

Why? Many of today's teens are spending their free time with microcomputers and video games, popular music, and the endless channels of cable TV. Most of these youths will not discover hobbies until they reach college where clubs and organizations promote various interests, or until they mature a little and begin to consider computers as something you use at work, lose their interest in pop music, and grow bored with TV. As a result, the average age of almost all traditional hobby groups is shifting up a little.

While the shifting age of operators is nothing to worry about, declining membership is a real problem. The solution is not changes in the rules, but simple public relations. I won't oppose a no-code license if it will do what its proponents say, but I don't think it will. My experience has been that once a person gets excited about amateur radio, the code is a very low hurdle to step over.

The real problem we have in at-

tracting new members is the uninteresting image of amateur radio today. Too many people view the hobby as a bunch of old men gossiping with each other. This problem has been frustrated by the advent of cheap shortwave receivers and scanners, bought by people hoping to hear stations from all over the world. Unfortunately, these radios and the antennas people use are so poor that they generally end up with only Radio Moscow, BBC, VOA, WWV and the ham down the street. When they do get stations from faraway places, they quickly discover that people in Norway really do speak Norwegian.

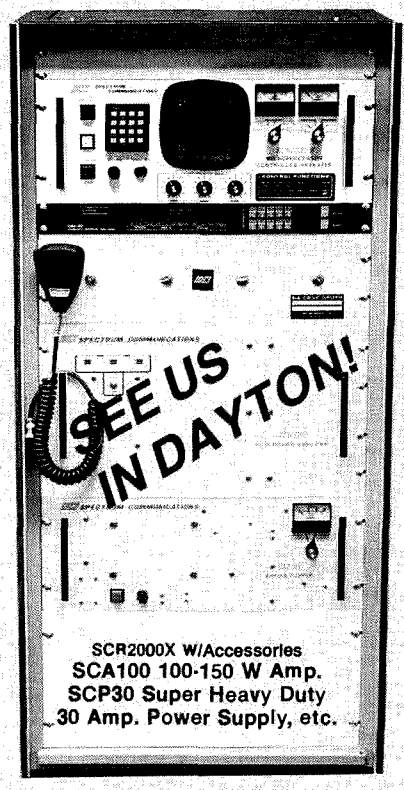
So they tune to the amateur bands and gain first-hand experience with what amateur radio is all about, or so it seems to them: endless, purposeless rag-chewing; traffic nets with no traffic; rude contest operators; "contacts" that consist of nothing more than name, location, signal report, and "Send me your QSL card, I need it for my worked-all-states award."

Scanner listeners, meanwhile, are finding that paging has gone digital, that radio telephone has moved to 800 MHz (above the coverage of many scanners), that it's hard to follow a conversation through a trunked repeater system and that a $50 "descrambler" from the local radio shop will not crack Motorola DVP. So they too turn to the ham bands. Here they either find one repeater that's so busy the operators have to fight each other, or 50 repeaters each occupied by one operator with, by strange coincidence, the same call sign as the repeater.

Next time you're on the air, especially you VHF and UHF repeater users, think about this: What kind of image are you presenting to the non-amateurs who are listening?

The real solution to this problem is for local clubs to become more active. I know, in the past, local clubs have tried to maintain a low profile to avoid being blamed for every speck of snow on every TV in the area, but it's time to come out of the closet and make your organizations visible. Let's show the public what amateur radio is really all about: public service, emergency communications, technical development and, of course, a lot of good fun.

Chuck Gollnick KA7QEN/0
Ames IA



Chuck, I've been hamming for 47 years now and you've described 95% of what I've been hearing for 47 years—endless, purposeless ragchewing, rude operators, pileups, contest-type contacts, and thousands of repeaters with but one operator using 'em. What we have to do is convince kids that endless, purposeless ragchewing and contest-type contacts are by golly real fun. If we promise 'em anything else we're lying. I'd have to lump our public service, emergency operating, technical development and interesting ragchew contacts in the 5% bracket if I were going to be honest.—Wayne.

"When You Buy, Say 73"

new *In repeaters, there's*
NO COMPARISON

For your new or upgraded Repeater/Link System, you won't find a better quality or higher performance machine than the New SCR2000X.

This highly advanced unit includes a wide array of DTMF Remote Control Functions, Automatic Digital Controls, and a full complement of front panel local control, test and metering functions. The 2000X is a commercial grade repeater which provides RF performance superior to any competitive unit. *And it's built to last—for years and years—by* **Spectrum**...the people with over a decade's experience in worldwide repeater/link systems.

SCR2000X W/Accessories
SCA100 100-150 W Amp.
SCP30 Super Heavy Duty
30 Amp. Power Supply, etc.

STANDARD FEATURES
- Autopatch/Reverse Patch, W/0 & 1 inhibit
- Dial Pulse Converter ■ Autodialer
- Phone line & "over the air" command modes. Virtually all functions may be turned on/off remotely.
- Touch Tone Control of 'Timeout', 'Hang Time', Patch Timeout, TX Inhibit/Reset, Patch & Reverse Patch Inhibit, Reset, P.L. ON/OFF (w/optional P.L. board), etc.
- Up to 6 Auxiliary Functions. More with TTC300.
- Full 16 Digit Decoding with Crystal Controlled Decoder IC
- Touch Tone Mute ■ "Kerchunk Killer"
- Unique Courtesy Tones
- Timeout Warning Tones
- Automatic CW ID & ID Command
- Remote Programming of 3 Timers for 2 different timing cycles, or No Time Out
- Microprocessor Memory 'Battery Backup'
- Autopatch AGC for constant levels
- Local Status indication via 12 Function panel LED Display
- Front panel Touchtone Pad for Local Control & Phone line access.
- Full Panel Metering: Rcve. & Xmtr. functions plus Voltages & Currents
- **New-Improved: RCVR, UHF Xmtr., Power Supply!**
- 30–75 Watt VHF & UHF Models
- 100–150 Watt Final Amps Available
- SC200X Microprocessor Controller & Interface Boards also available. Same features as above.

SPECTRUM'S 2000X
Microprocessor controlled repeater

NEW PRODUCTS

HAPN INTROS PC PACKET ADAPTER

The Hamilton and Area Packet Network has introduced a plug-in terminal node controller (TNC) for the IBM PC and compatibles. The card includes the TNC, a Bell 202-style 1200-baud modem, and a pre-drilled prototyping area.

Bare boards are available for $75, and an assembled/tested unit costs $199; contact *HAPN at Box 4466, Station D, Hamilton, Ontario, Canada L8V 4S7.* Reader Service number 150.

REGENCY HX1200 SCANNER

Regency Electronics now offers the HX1200 hand-held scanner. The HX1200 covers eight bands: 30–50 MHz, 118–136 MHz, 144–148 MHz, 148–174 MHz, 406–420 MHz, 440–450 MHz, and 470–512 MHz. Frequencies may be stored in any of 45 keyboard-programmable channels.

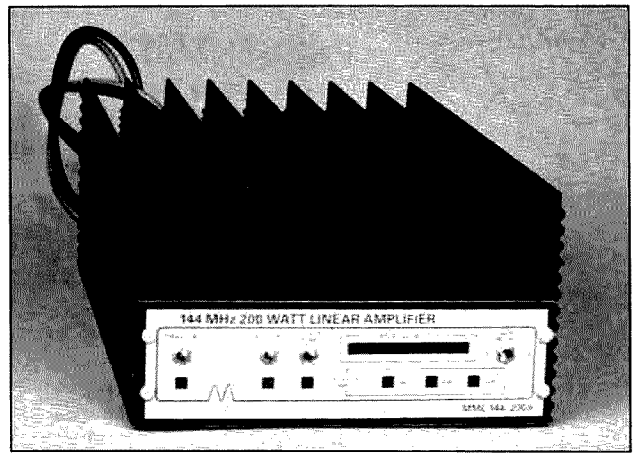
The Regency HX1200 is priced at $369.95 and comes with a wall charger, carrying case, belt clip, flexible antenna, earphone, and nickle-cadmium batteries. For complete details, contact *Regency Electronics, Inc., 7707 Records St., Indianapolis IN 46226.* Reader Service number 151.

Regency's HX1200 VHF/UHF Scanner.

ESP UPS

Electronic Specialists is now marketing an uninterruptable power supply. The UPS is capable of supplying power for up to 20 minutes, and outputs a clean sine wave. The internal batteries are automatically kept at full charge.

Two models are available for power requirements of 250 or 500 Watts. Options include power line phase-lock, blackout illumination, and provision for an external battery.



For further information, contact *Electronic Specialists, Inc., 171 South Main St., Natick MA 01760; (800)-225-4876.* Reader Service number 152.

ACC SOFTWARE UPDATE

Advanced Computer Controls has released new software for its RC-850 Repeater Controller.

Version 3.4 supports multiple telephone lines (including up to three lines linked by radio), expands autodial storage to 250 telephone numbers, adds slots for 35-digit dialing sequences, and offers several modes of paging, such as five-tone sequential, DTMF, CTCSS, and HSC. Analog measurements performed by the controller have been enhanced to include stored low and high values on each channel, tagged with the time and the date. The controller also keeps track of internal functions such as number of key-ups or autopatches.

For information about the RC-850 Repeater Controller, or to find out how to upgrade your RC-850 to Version 3.4, write or call *Advanced Computer Controls, Inc., 10816 Northridge Square, Cupertino CA 95014; (408)-749-8330.* Reader Service number 153.

Microvave Modules' MML 144/200S.

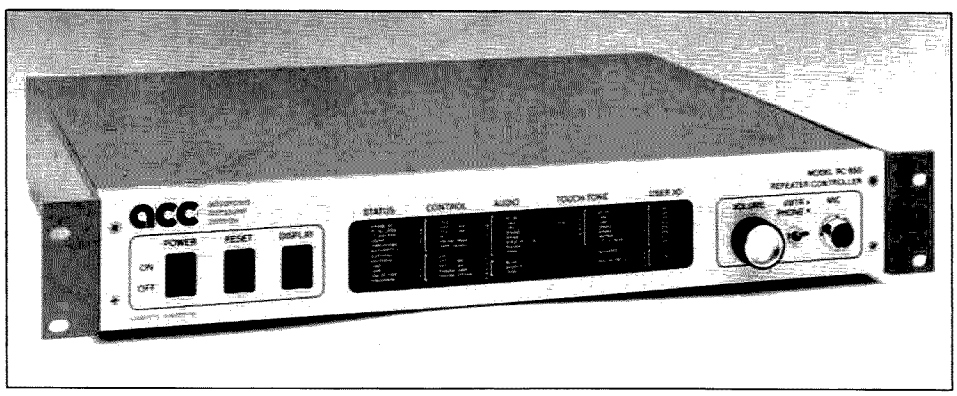
SELECTABLE-INPUT 2M AMP

Microwave Modules of Liverpool, England, has announced the Model MML 144/200S 200-Watt linear amplifier for 144 MHz. The input power level is switch-selectable between 3, 10, or 25 Watts, making it compatible with nearly every 2m radio on the market (including hand-helds). Both rf VOX and a manual PTT line are available.

The MML 144/200S also includes a built-in GaAsFET receive preamplifier with a noise figure of less than 1.5 dB.

For complete details about the MML 144/200S, contact *The "PX" Shack, 52 Stonewyck Drive, Belle Mead NJ 08502; (201)-874-6013.* Reader Service number 154.

NEW HEATH HT



Heathkit has announced the HW-6502 2m hand-held/mobile transceiver. The HW-6502 covers 144–145.995 MHz and has a receive sensitivity of .25 uV.

A mobile console, the HW-6502-2, is available that houses the transceiver and is able to boost the transceiver's output to 25 Watts with an optional amplifier. The console provides power and switching and features a lighted frequency display.

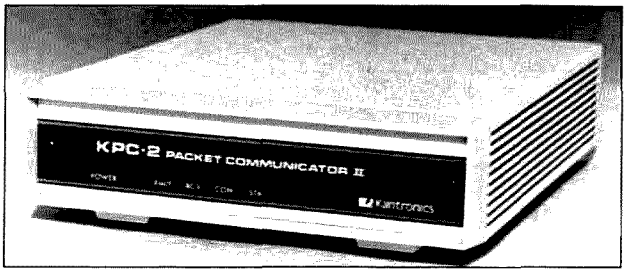
For more information about the HW-6502, or for a complete catalog of electronic products and kits, write *Heath Company, Dept. 150-735, Benton Harbor MI 49022.* In Canada, contact *Heath Company, 1020 Islington Ave., Dept. 3100, Toronto, Ontario M8Z 5Z3.* Reader Service number 155.

CSI MICROMINIATURE ENCODER/DECODER

Communications Specialists has announced the TS-32HB Super-Microminiature Programmable Encoder/Decoder. The encoder comes in two styles: The TS-32HBH measures 1.5"x.65"x .65", while the TS-32HBL is 1.5"x 1.2"x.4". Both units are de-

The RC-850 Repeater Controller from ACC.

signed to fit within the confines of miniature hand-held radios.



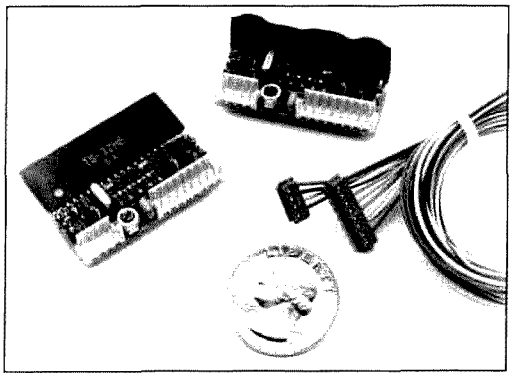
Programming of the 32 available EIA tones is via a board-mounted DIP switch. Input sensitivity is rated at 6 mV rms and the decode bandwidth is ±1.5 Hz. The adjustable output measures up to 6 V across a 10k resistance.

The TS-32HB is available for $64.95; for further information, contact *Communications Specialists, Inc., 426 West Taft Ave., Orange CA 92665-4296; (800)-854-0547.* Reader Service number 156.

A.P.E. DESOLDERING PUMPS

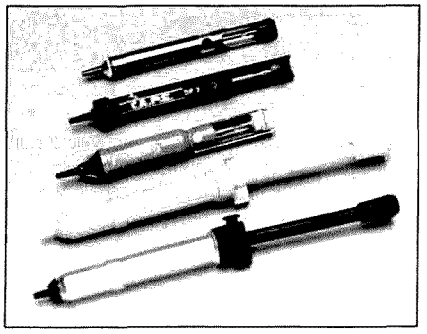
Automated Production Equipment has announced five new hand-held desoldering tools, each designed to address a specific problem in component removal. The DP-1 features all-metal construction and an anti-static tip. Model DP-2 combines an anti-static body with a conductive tip. Models DP-3 and DP-4 are all-plastic; the DP-3 has extra capacity and the DP-4 incorporates a spring-actuated return mechanism. The DP-5 is spring-actuated, conductive, anti-static, and comes with an anti-static tip.

For more information, contact *Automated Production Equipment, 142 Peconic Ave., Medford NY 11763.* Reader Service number 157.



The Kantronics Packet Communicator II.

KANTRONICS KPC-2



A new terminal node controller, the KPC-2, is now available from Kantronics. The TNC features multiple connects (up to 26 at a time), a built-in HF modem, RS-232C or TTL operation, and AX.25 version 2 protocol.

If you are having trouble easing into packet technology, consider *Basic Packet*, a video tape designed to teach the fundamentals.

For more information about the KPC-2, or about *Basic Packet*, contact *Kantronics, Inc., 1202 East 23rd St., Lawrence KS 66046; (913)-842-7745.* Reader Service number 158.

CSI's TS-32HB CTCSS encoder/decoder.

A variety of desoldering tools from A.P.E.

The Dayton Hamvention '86

The Center of the Ham Radio Universe

It's almost that time again—time for ham radio's biggest bash of the year, the annual Dayton Hamvention on April 25, 26, and 27.

If you've been to any of the Hamventions over the past 34 years, you know why folks tend to get excited about this time of the year. But if you are one of the few, disadvantaged people who has never had the privilege of spending three days at what some fans call "the center of the ham radio universe," then you've got some learnin' to do.

I'm sure most of you have been to a hamfest and have enjoyed yourself. It's great to check out some of the old and new gear and have a chance to meet some of the old and new hams. And most events feature drawings where you have a chance to win a piece of gear donated by a local dealer. In short, hamfests are a lot of fun.

Now take your local hamfest and enlarge it. Spread out the flea market to cover over 1,500 spaces and increase the inside display area to accommodate more than 200 dealers. Then print up enough tickets, flea market permits, and programs for an anticipated crowd of over 22,000 people. Finally, set up the drawing to have hourly prizes, with the top prize being a complete amateur radio station.

Now make it a three-day, international event and instead of expecting hams from all parts of your home county, expect guests from all over the world. If you can successfully relate those changes to your local hamfest, then you have a good idea of what the hamvention is like. Of course, the best way to know what a Hamvention really is like, is to experience it for yourself!

Planning Your Trip

The first thing you need to do—assuming you're a member of the working class, like most of us—is get off work for the days of the Hamvention, April 25, 26, and 27. Since April 26 and 27 are a Saturday and Sunday, you'll probably need to use only one vacation day, Friday, April 25. Then again, if you need a day to travel to Dayton, also ask for Thursday off. Don't worry about using up two whole days of vacation—the Hamvention is well worth it.

Next, get together with your local hams and find out how many are interested in making the trip. You'll probably find a few who have been before and some others who have wanted to attend but have been waiting to go with a group. Tell them the dates they'll need to be off work, and that they'll probably need about $100 to cover the expense of the trip.

How did I come up with that figure? From experience I can tell you that $100 will just about pay for one person's tickets, share of the food, travel expenses, and motel accommodations. That amount will vary, of course, depending on how far you have to travel, what method of travel you use, where you stay in Dayton and what restaurants you pick, but overall that $100 figure is a pretty good starting place in estimating basic costs. Each year, we travel by car about 500 miles from West Memphis, Arkansas, to Dayton, Ohio, and when we end up splitting the expenses, that's about how much it comes to for each of us. So if you live farther from Dayton, add $25 or $50 to be on the safe side.

Here's a money-saving tip: If you plan early, order your room reservations through Hamvention Housing, 1980 Kettering Tower, Dayton, OH 45401-1980. Most area hotels and motels work with Hamvention Housing and offer a special rate for guests during the Hamvention. Although no reservations are taken by telephone, you can get more information about room rates and locations by calling Hamvention Housing at (513) 223-2612.

Covering Expenses

Now that I've told you how much it should

Photo A. SRO inside the main exhibition hall. Recognize anyone?

cost you to attend the Hamvention, wouldn't it be nice if I had a magic formula you could use to pay for the trip? Hold on to your rubber duckies fellow hams, I'm just about to pass that along.

One of the biggest attractions of the Hamvention is its 1,500-space flea market. It's large enough to cover about two city blocks and it usually contains at least one of every amateur radio doo-dad ever marketed. If you want it, you can find it at Dayton. And if you can't find it at Dayton, you'll probably never find it!

Now, if you'll look around your shack or garage, I'm sure you'll find a few items that you've been meaning to take to the local hamfest and sell. The local hamfest attracts a limited crowd, however, and that certain buyer might not be there. With over 22,000 people attending the Hamvention, that's a problem you won't have at the Dayton flea market.

So here's how to pay for your trip. Order a flea market space for your group when you order your registration tickets. Flea market spaces have gone up this year from $17 to $20, but if you split that four ways, it's only costing you $5 and you should be able to make that back on your first sale. Remember—that $20 pays for the space for all three days!

If everybody in your group brings a few items to sell, then you all can cover your expenses. And if you take turns manning the booth, then everybody gets a chance to make a raid on the flea market. Also, it's a BIG flea market, and few people have the stamina to cover the entire area in one trip. Your flea market space gives you a place to rest. Finally, your space becomes a location for the members of your group to congregate. For all of these reasons, the flea market space is a bargain, and if you work it right, should pay for itself and help you pay your trip expenses.

If you're sold on getting the flea market space, keep these simple rules in mind: Spaces are sold in advance only, and your registration tickets should be ordered at the same time.

Send requests for flea market spaces ($20 each, limit four) and tickets ($8 each) to Dayton Hamvention, PO Box 2205, Dayton OH 45401. In the left-hand corner write FOR FLEA MARKET REGISTRATION.

No bikes, motorized skateboards, or roller skates will be allowed in the flea market. If you plan to use a gas heater or stove, please protect yourself and others and have a fire extinguisher available.

Persons holding flea market permits and registration tickets can enter the flea market beginning at 8 a.m., Thursday, April 24 to set up their numbered, assigned space.

If you have any other questions about the flea market, you can call the special Flea-Market Hotline at (513) 223-0923. You'll be getting your information firsthand since you'll probably be talking to Flea Market Chairman John Grody or his lovely wife, Cathy, but keep in mind this phone is in their home—so try and call before 10 p.m. EST.

Photo B. The flea market stretches on and on.

What You'll See

Okay, now that I've told you where to go and how to pay for it, maybe I could give you a little preview of what you might be seeing at this year's Hamvention.

I've already mentioned that you can expect to run into a crowd of 22,000 people, but let me add that the Hamvention organizers have planned to accommodate such a large group. I've never had to stand in a line longer than one or two people to buy a drink or a sandwich, and if you'll try to eat prior to the noon hour, you should be able to avoid the lunch crowd.

"No bikes, motorized skateboards, or roller skates will be allowed in the flea market."

One other time you might stand in line is to take advantage of an incredibly low price on some of the newest, most popular amateur gear. If you are looking for the best price on that certain piece of equipment you've been dreaming about, you'll probably find it at Dayton.

For example, I found a package of 10 floppy disks to range in price from a high of $12.95 to a low of $7.95. The $7.95 offering was a good quality disk, so guess which one I bought? These quickly sold out but later on, I noticed the $12.95 price had been cut to $10.95 and eventually this dealer also sold out.

This brings up an important point—how low can the prices get and when should you buy? No one owns a crystal ball, but I usually pick a price beforehand that I am willing to pay and if I can get it for that price then I'm happy. In some other cases, when to buy depends on what the item is. If it's a handi-talkie, there's always a great demand at Dayton. They usually sell out fast, so find the lowest price and buy immediately. If it's a high-priced item like a deluxe low-band rig, the demand should be less and you should have more time to shop.

One important buying rule at Dayton: Prices are usually at rock bottom on Sunday when the dealers are packing up, so buy then, or buy on Friday and Saturday but ask the dealer for his Sunday price.

One shopping tip—you might want to jot down on a piece of paper some of the items you definitely want to purchase while you're at the Hamvention. After all, there are three large inside areas for the more than 200 exhibitors in addition to the flea market, and with so much to look at you could forget what you intended to purchase.

One thing I can guarantee you'll see at Dayton is the newest in amateur radio gear. Manufacturers like to display their state-of-the-art gear to the largest crowd possible, and that obviously means unveiling it at Dayton. They might not have gone into production yet on what they show so you might not be able to buy it, but you will definitely be able to see the prototype and get an idea of what the future of amateur radio is going to be.

Dayton also offers the unique opportunity to talk directly with the person who designed a particular piece of equipment. These days you might need to know how to speak Japanese to do so, but in many cases I have found the inventor also manning the booth and available to answer every question you can think of about his electronic brainchild.

The Weather

I have to hand it to the Hamvention organizers! For the last two years they've been able to arrange for absolutely perfect weather. But just because there were clear skies and moderate temperatures for the last two years is no guarantee it will happen again for the

Photo C. Only one more day to go!

1986 Hamvention. In fact, the best way to handle the Dayton weather is to plan for the worst, which could mean freezing temperatures and constant downpours.

Keep this changeable weather possibility in mind as you pack your weekend bag, and let practicality rule. Jeans will be standard, but be smart and toss in long underwear just in case the weather makes a chilling change.

On top, start simply with a T-shirt, then add a long-sleeved shirt (you can roll up the sleeves if it gets too warm), a medium-weight jacket and then finish with a waterproof or rain-resistant coat. Now you're ready for the cold and rain—and if the weather is warm, you can take off the coat and jacket as needed.

One last thing. Bring along a heavy coat and keep it handy. That way, if the temperature takes a deep dip you'll be ready.

The Big Day

After all of the planning, your big day at Dayton finally arrives! It's April 24, you're in the Wright Brothers home town, and you're wondering what is the first thing you should do.

Never fear, your guide is here! My suggestion: take a quick run over to Hara Arena and check the place out. Don't know how to get there? Follow these simple directions. Take Interstate 75 to Needmore Road and exit west, turn right on North Main, then turn left on Shiloh Spring Road, and watch for Hara Arena to be on your right.

Next, you should secure your accommodations. Then, depending on the time you have available, you might want to visit the New Air Force Museum at Wright-Patterson Field (just 10 minutes from downtown Dayton) or the Dayton Museum of Natural History, 2629 Ridge Ave. (home of the Dayton Amateur Radio Association Club station, W8BI).

On Friday, it's a good idea to get an early start, but keep in mind that the Hamvention does not open until noon. That gives you plenty of time to eat breakfast, drive to Hara Arena and get your flea market space ready for customers.

Once the Hamvention begins, persons holding tickets are allowed to wander freely inside and out but are required to show their tickets whenever they enter the indoor exhibits. The first time you go inside, enter through the front doors of the Silver Arena and you'll receive your copy of the official Hamvention program.

Find a seat in the arena stands and take a minute to look over the program and the schedule of activities. You'll see the times and locations for all of the planned forums. These times are definite, and if you wish to attend a particular forum plan your shopping sprees around it.

On Saturday, the flea market opens at 6 a.m., while the inside exhibits open at 8 a.m. Both close at 5 p.m., much earlier than Friday night's closing time of 8 p.m. This is to allow those who are attending the Hamvention banquet time to change and drive downtown to the Dayton Convention Center.

Tickets for the banquet are available for $14 in advance or $16 at the door (if available then), and if you've never attended, maybe you should include this event in your Hamvention plans. Each year at the banquet, awards are given for Radio Amateur of the Year and for special achievements in amateur radio. There is always an interesting featured speaker. Add to that a great meal, and you know why many amateurs consider the banquet the high point of the weekend.

The flea market opens at 6 a.m. again on Sunday and inside exhibits at 8 a.m., but buying and selling activity starts to slow down as the time for the prize drawings nears. Yes, prizes are awarded all during the Hamvention weekend, but for those unclaimed prizes, another drawing is begun at 2 p.m., and is then followed by the drawing for the major prizes at 3 p.m.

Last year, the top prize was a complete ICOM station, so if you feel lucky you might want to stick around on Sunday afternoon!

Additional Activities

There's not enough space here to write about all of the activities that are planned in conjunction with the Hamvention; I have hit only the highlights. There are also alternative activities (formerly women's activities), FCC license examinations, YL forums, CW proficiency awards, and forums on almost any aspect of amateur radio.

The Hamvention also furnishes a shuttle-bus service to carry you to and from all participating hotels and motels, Hara Arena, the Air Force Museum, and to the Dayton Convention Center for the Saturday night banquet.

So this year plan to be a part of the Dayton Hamvention. Get a group together and follow the steps listed below for a very enjoyable weekend at "The Center of the Ham Radio Universe," April 25–27. My guess is that you'll have a fantastic time and find yourself doing what we do on the trip back home—planning for next year's excursion to the Dayton Hamvention!

General Information

- Hamvention Information—(513) 443-7720.
- Flea Market Hotline—(513) 223-0923.
- Housing Information—(513) 223-2612.
- Flea Market Setup Day—April 24. Registration tickets and flea-market permits must be shown together for admission to the flea market prior.
- Prices—Registration Tickets $8 in advance, $10 at door; flea market spaces $20; banquet tickets $14 in advance, $16 at door (if available). ■

CHECKLIST

- ☑ Get the group together to see who wants to go, then figure on how many cars you'll need to make the trip.
- ☑ Talk to the boss and arrange to have April 25 off (and April 24 if you need a travel day).
- ☑ Secure room reservations for the nights of April 25 and 26, and if you plan on arriving Thursday, include the night of April 24 in your reservations.
- ☑ Order your registration tickets and flea market permits early and at the same time.
- ☑ Save your money for the trip and gather your flea market space. Be sure to convert your cash to traveler's checks before leaving home. Don't expect sellers to accept your personal check.
- ☑ Make and carry a list of things you want to buy at the Hamvention. There's so much to see, you might forget what you intended to purchase.

Your Bridge Over Troubled Antenna Tuning

Is your antenna less than ideal? Put more fire in the wire.

The popularity of resonant antennas fed by "flat" coax lines has led to the development of bridges of various types to aid in antenna tuning, line selection, and the design and adjustment of stubs and impedance-matching networks. The proper adjustment of an antenna system requires that a signal be radiated for considerable lengths of time. If you use an appreciable amount of power, this signal may create needless and annoying interference.

The bridge I'll describe here supplies only 2.5 milliwatts to the feedline; it regains sensitivity by employing a dc amplifier between the rectifier and the meter. The internal crystal oscillator will operate at any frequency from 160 through 10 meters on either fundamental or overtone modes. It is crystal-controlled because antenna systems are frequency-sensitive; quartz is the simplest and probably the least expensive way to insure stability. The entire unit, including batteries, is housed in a cabinet so that it can be moved to "where the action is."

The Bridge

A resistance bridge is simpler than an impedance bridge. It shows its deepest null in the absence of reactance. Reactance at the antenna end of a line is never desirable. Hence a resistance bridge is adequate for matching antennas to line provided that it is always used with a repeating line (See Note 1). Referring to Fig. 1, the bridge uses a pot for "differential resistance" balancing. This arrangement yields an open scale in the range 0–5 Ohms, characteristic of low antennas and close-spaced arrays, and an increasingly compressed scale extending to over 1,000 Ohms. In this way, a large range is achieved by a low-resistance pot. It's important to minimize bridge resistances to reduce errors, particularly at high frequencies. It also is important to minimize the capacitance of the pot to ground; this is done by mounting it off ground and using an insulating shaft coupling. The usual precautions of minimizing lead lengths, orthogonal mounting of parts, shielding, and so on, are observed.

The Oscillator

For accuracy, this type of bridge requires a closely sinusoidal exciting voltage. Clean waveforms are easily produced only with tuned-circuit oscillators. A link winding is a simple way to match the oscillator to the low bridge resistance. The Pierce circuit will operate with crystals of highly variable activity. The "Tuned Pierce" circuit will excite the fundamental or odd overtone modes of most crystals, regardless of their labeling—hence the choice of this circuit.

Two ranges are switch-selected: 1.75–7 MHz, and 7–30 MHz. The large ranges are made possible by maximizing the ratio of maximum to minimum capacitance shunting the coils. This is done by the use of a large variable capacitor having a large inherent-capacitance ratio, coils with low distributed capacitance, and care in reducing strays, such as mounting the switch and crystal socket off ground and minimizing lead lengths. The gate is biased by the dc-restorer action of the diode. No source resistor is used because the large g_m at zero bias encourages oscillation to start. Transistor dissipation is within rating at zero bias.

The Dc Amplifier

I selected a dual J-FET op amp because it has high input impedance, low offset voltage, low input current, and internal-drift compensation. The first stage uses the non-inverting circuit so

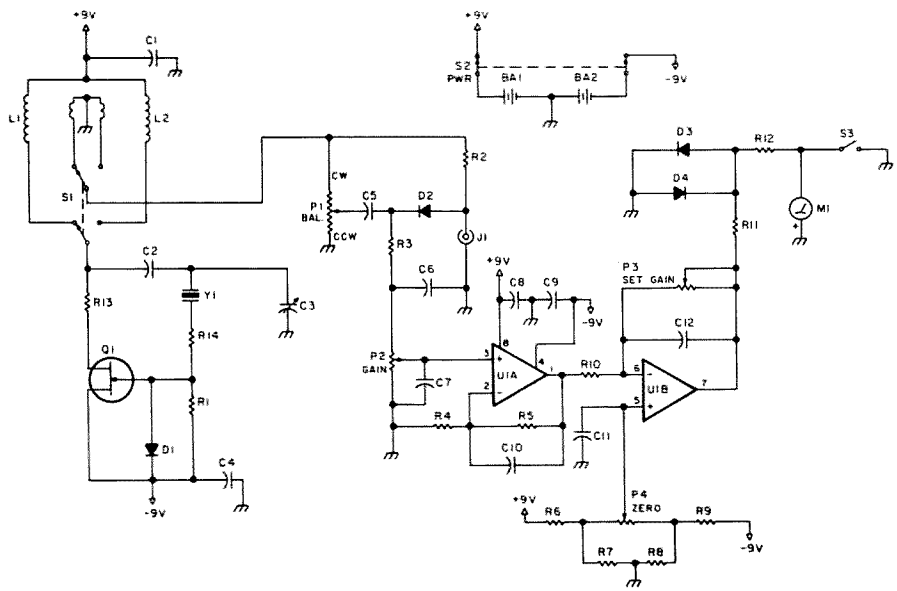

Fig. 1.

that the gain pot may operate into a virtually open circuit, ensuring that the gain of the entire amplifier varies upwards linearly from zero. The gain from pin 3 to pin 1 is fixed at 11. Large capacitors are used throughout the circuit to reduce the gain for all frequencies except dc; limiting the bandwidth suppresses the oscillator signal and reduces noise.

". . . the sensitivity is adjustable over a very large range. . ."

The second stage uses the inverting circuit with gain adjustable from zero to 10 by means of a variable feedback resistor. The zero pot supplies a small variable bias of either polarity to a virtually open circuit. This bias neutralizes the offset voltages of both amplifier stages. It also is useful for setting the meter upscale so that the null is more easily observed.

The meter is protected at about twice full scale by the back-to-back silicon diodes, which are in turn protected by the 1k resistor. The amplifier is internally protected. The meter shorting switch is used to eliminate transient deflections caused by battery switching.

Calibration

Although a theoretical calibration is easily derived, it is not accurate because the pot is not exactly linear. Accurate calibration is made by connecting resistors of known value to the rf connector, balancing the bridge, and marking the scale accordingly. The half-Watt carbon resistors are soldered inside PL 259 connectors and, when cool, bridge-measured at dc. An ohmmeter may be used if the lower accuracy is tolerable.

Substitutions

Use the specified coils; otherwise it may not be possible to achieve the wide tuning range. Some careful pruning may be required anyway because of variations in wiring and parts placement.

Under no circumstances substitute for the balance pot. The Ohmite AB pot is the best affordable component available. It has low inductance and capacitance, and it's quiet.

Bridge Operation

UHF parasitic oscillations indicate their presence by tunable meter indications not controlled by the crystal. They were suppressed in this case by R13 and R14. Crystal modes are easily identified because the tuning is asymmetric and abrupt. It's best to check the oscillator on a receiver to be sure it is crystal-controlled and starts dependably. This adjustment may then be forgotten until the frequency is changed.

The null position is set by turning the gain pot to zero and moving the meter pointer a few divisions upscale by means of the zero pot. This setting will be stable for a long time. The operation of the bridge is like that of any other bridge except that the sensitivity is adjustable over a very large range—in fact, the maximum usable sensitivity is set by brush noise in the balance pot.

Antenna Tuning

Since the subject is complicated, I'll limit discussion to the procedure for the horizontal half-wave coax-fed dipole with a 1:1 balun. The best that you can do here is to resonate the antenna and measure its feedpoint resistance. You can then make a decision on a method of feeding it.

The antenna is connected to the bridge by means of a repeating line that is long enough to reach from the final position of the antenna to the ground. (See Notes 1 and 2.) This brings the bridge, in effect, to the feedpoint, but the operator and the gear are safely on the ground where, because they are well removed from the radiating wire, they do not distort the field. Starting with the antenna symmetrical and too long, consecutively null the bridge and make small symmetrical changes in antenna length until the deepest null is obtained (See Note 3). Here the antenna is resonant, the reactance is zero, and the bridge reads the feedpoint resistance.

In the unlikely event that this resistance matches a standard coax, the appropriate line may be connected and run any length into the shack. In any other case there will be standing waves on the line and it matters how long the line is. Even though the feedpoint impedance is a pure resistance, the input impedance of the line will have reactance unless it is either a repeating or an inverting line. (Notes 4 and 5.)

The inverting line may be useful in two cases. When the feedpoint impedance is 33.3 Ohms, a 50-Ohm inverting line will make the input impedance 75 Ohms. And when the feedpoint impedance is 112.5 Ohms, a 75-Ohm inverting line will make the input impedance 50 Ohms. I have used the first arrangement with a very low dipole. The second may not be practical, since theory asserts that the maximum feedpoint resistance is less than 100 Ohms.

Probably the best solution is to install a repeating line having Z_o closest to the feedpoint resistance so that the swr will be minimized. If the transmitter will not load properly, the line-input impedance may be transformed to 50 Ohms resistive by means of a pi section filter or other simple matching network.

Discussion

All antennas are less than ideal due to economic and physical restrictions, but a given antenna will work better if it has more current in it. It will have more current in it for a given transmitter dc input power if it is resonant

1986 CALLBOOKS

The "Flying Horse" has a great new look!

It's the biggest change in Callbook history! Now there are 3 new Callbooks for 1986.

The North American Callbook lists the amateurs in all countries in North America plus those in Hawaii and the U.S. possessions.

The International Callbook lists the calls, names, and address information for licensed amateurs in all countries outside North America. Coverage includes Europe, Asia, Africa, South America, and the Pacific area (exclusive of Hawaii and the U.S. possessions).

The Callbook Supplement is a whole new idea in Callbook updates. Published June 1, 1986, this Supplement will include all the activity for both the North American and International Callbooks for the preceding 6 months.

Publication date for the 1986 Callbooks is December 1, 1985. See your dealer or order now directly from the publisher.

☐ North American Callbook
incl. shipping within USA $25.00
incl. shipping to foreign countries 27.60

☐ International Callbook
incl. shipping within USA $24.00
incl. shipping to foreign countries 26.60

☐ Callbook Supplement, published June 1st
incl. shipping within USA $13.00
incl. shipping to foreign countries 14.00

SPECIAL OFFER

☐ Both N.A. & International Callbooks

and properly fed. This bridge will enable you to adjust the length to resonance, and will also suggest the best method of feed. Use it to get more "fire in the wire."

Notes

1. A repeating line is an even multiple (2, 4, 6, etc.) of a quarter-wave long, electrically. Its input impedence is equal to its terminating impedence. For this application, its surge impedence does not matter.

2. Measurements made in other than this final position will be of little value because the feedpoint impedence varies widely with antenna height and position with respect to other objects.

3. Shortening each end of a 40-meter dipole by one inch will raise the antenna resonance about 18 kHz. The effect increases roughly with the square of frequency, i.e. $\Delta f(kHz) = f(MHz)^2/2.72$ approximately.

4. An inverting line is an odd multiple (1, 3, 5, etc.) of a quarter-wave long, electrically. It obeys the relation $Z_i = Z_o^2/Z_T$ where Z_i is the input impedence, Z_o is the surge impedence, and Z_T is the terminating impedence.

5. Terman (*Radio Engineers' Handbook*, 1st edition, McGraw Hill, 1968, page 186). Eq. (62) may be written $y + A \cos \theta + j\, B \sin \theta / B \cos \theta + j\, A \sin \theta$, where $y = Z_i/Z_o$, $A = Z_T$, $B = Z_o$, and θ = angular length of the line. (Or see any text transmission lines.)

Multiplying the numerator and denominator by the conjugate of the denominator will result in the denominator becoming a pure real number. For this proof we find the cases where the resulting numerator is a pure real number. It is $g = (A \cos \theta + j\, B \sin \theta)(B \cos \theta - j\, A \sin \theta) = AB\ (\cos^2 \theta + \sin^2 \theta) + j\ (B^2 - A^2) \sin \theta \cos \theta = AB + J\ 1/2\ (B^2 - A^2) \sin 2\theta$.

We exclude the case where $A = B$ because we are considering only lines mis-terminated in a pure resistance. G will be a pure real number only when $\sin 2\theta = 0$, which occurs only when $\theta = n\ (90°)$, where n is any integer. Since 90 degrees is an electrical quarter wave, the input impedence will be a pure resistance only for line lengths an integer number of quarter waves long, electrically. This means that either a repeating or an inverting line must be used to avoid reactance in the line output impedence. ■

Parts List

BA1, BA2	9-volt transistor battery
C1, C2, C4, C7–C12	0.05-µF, 50-volt disc ceramic
C5, C6	0.1-µF, 50-volt disc ceramic
C3	730-pF air variable (dual 365 pF with sections paralleled)
D1, D3, D4	1N914 silicon switching diode
D2	1N34A germanium point contact diode
J1	SO-239 rf connector
L1	64T #24 tinned wire 1/2" i.d. 2" long B&W Air Dux #432-T (entire coil) link 6T hookup wire. Substitution not advised.
L2	12T #18 tinned wire 1/2" i.d. 1 1/2" long B&W Air Dux #408-T (remove 4T) link 3T hookup wire. Substitution not advised.
M1	50-µA meter, 1.9k internal resistance
P1	100-Ohm pot, linear taper, Ohmite Type AB Style CMU 1011. *Do not substitute*. Mount off ground.
P2	50k linear taper pot, Ohmite Type AB
P3	100k linear taper pot, Ohmite Type AB
P4	10k linear taper pot, Ohmite Type AB
Q1	N-channel FET (Radio Shack #276-2035)
Resistors all ½-Watt carbon composition	
R1	220k
R2	50 Ohm (select from 47-Ohm stock)
R3	8.2k
R4, R10	10k
R5	100k
R6, R9	47k
R7, R8	680 Ohm
R11	1k
R12	4.7k
R13, R14	22-Ohm UHF parasitic suppressors *required*
S1	DPDT toggle (mount off ground)
S2	DPST toggle
S3	SPST toggle
U1	Dual BiFET op amp Type LF 353 N (Radio Shack #276-1715)
Y1	Ceramic crystal socket for HC6/U; Crystals (mount off ground)
Cabinet	5 x 6 x 9 Bud AU 1040, CU 1099, etc.

Stretch the GP Antenna to the Max

This, the simplest of all antennas, has much to recommend it.

If you've worked a number of Eastern European stations, you've probably been told by some of them that they were using a GP (general purpose) antenna. As their signal is often adequate despite quite modest power, you may well ask what is the secret.

A GP antenna is just a length of wire, usually as long and as high as circumstances permit. Such a wire will have a particular impedance at a particular frequency. Provided that this impedance (which will normally vary from band to band) can be matched by means of a suitable ATU to the output impedance of the transmitter (usually 50 Ohms), it will radiate. It will often radiate well because there are no feeder losses, and moving from one end of the band to the other presents no problem if the ATU is retuned. Although the GP is basically a multiband antenna, its radiation pattern will vary on different bands.

There are a few disadvantages. One end of the antenna is in the shack, which may be dangerous because of high rf voltage. There is also a greatly increased likelihood of causing RFI in the building. At low power, however, these disadvantages are minimal and they can often be overcome even at higher power.

The classical ATU is shown in Fig 1. If the antenna impedance is low, the antenna tap is moved down the coil until proper loading is obtained. Because this presents difficulties when the antenna is nearly an odd number of quarter waves in length, it then becomes necessary to use series tuning.

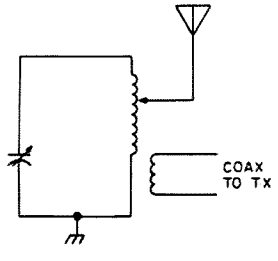

Fig 1. The classical antenna tuning unit.

You'll notice that there is a connection to ground from the bottom of the coil. Textbooks usually state that this should be as short as possible, and that the actual ground should consist of several copper rods. That's fine if your shack is in a hut at the bottom of your garden, but what do you do if you live in a 20th-floor apartment and, even if you get permission to run a wire down the building, can't bury the copper rods in the paved sidewalk?

"Although the GP is basically a multiband antenna, its radiation pattern will vary on different bands."

In recent years, this problem seems to have been side-stepped by using one of the newer forms of ATU. The Collins Universal Coupler (or π coupler) was around before World War II; since then there has been a spate of ATU designs, each claiming to be better than the last. Many of these designs avoid the link coupling shown in Fig 1. The ground connection is provided through the outer braid of the coax from the transmitter, and is usually connected to the common grounding system of the house wiring.

In most cases, this will work splendidly. I have had contacts with all continents using a π coupler and a length of wire thrown out of a bedroom window. However, as mentioned earlier, rf can appear elsewhere in the building. When other equipment is connected to the common grounding system, serious RFI might result, and standing waves on the grounding wires could cause high rf voltages in the common grounding wire! Except at low power, care is needed.

Many years ago, W3EDP suggested a solution to many of these difficulties. His antenna was 25.6 m (84 feet) long and used a short counterpoise in place of the ground connection. These lengths avoided tapping down the coil to obtain proper loading. His original ATU circuit involved inductive coupling between the PA output coil and the ATU coil. This arrangement is no longer practical. Recently, W3EDP's circuit has been rediscovered in Europe (see "Technical Topics" by Pat Hawker G3VA, *Radio Communication*, January, 1985, p. 35) and is proving quite popular. Link coupling is now used between the transmitter and the ATU.

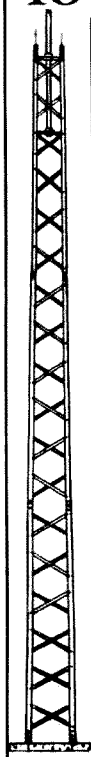

Fig. 2 gives the circuit. The variable capacitor should have about 1.5 pF for each meter of wavelength; a 150 or 200 pF capacitor will cover all bands from 3.5 MHz to 28 MHz with suitable inductances. Details of the coils and counterpoises for each band are contained in Table 1. It is helpful to have a tuning indicator as the tuning is quite sharp; a 500 uA meter and any small rf diode will suffice.

Wires from the meter are fixed near the ends of the tuned circuit to give slight capacitive coupling and the variable resistor adjusted to give a reasonable reading on the meter. Note that this reading will vary from band to band and is to be used only for tuning purposes. Because it does not indicate power level, the comparison of readings between different bands is quite meaningless.

Formerly, plug-in coils were common and would have been used for L1/L2. These are still around, but if you can't find any, wind the coils on a suitable bit of insulating material and glue this to an old tube base (if possible, use a UX4 as it has bigger pins than an octal one). This procedure may seem old hat, but it avoids the difficulties of using switches for the coils.

The W3EDP version of the GP obviates many of the difficulties associated with the use of a ground connection. There is still need for care to avoid burns from the antenna and, as there is no dc connection to ground, the antenna could be dangerous during a thunder-

TOWER VALUES

Rugged TRYLON ABC* towers designed and fabricated in Canada to survive the severe northern climate, now available in the USA at REASONABLE PRICES ranging from $330 to $2500 and heights between 32 and 160 feet.

EASY ASSEMBLY: Lightweight 8 foot triangular sections in a modular tapering design.

MADE TO LAST: High tensile strength steel and quality zinc coating (ASTM A-526 specification). Painting available. Zinc-plated steel bolts. Virtually maintenance free.

Guyed and free-standing versions available; shipped factory Direct and guaranteed ONE FULL YEAR after installation.

Write or call BJX SUPPLY CO. for full information and price sheet.

Table 1.

storm when very high voltages might develop. Otherwise, the W3EDP antenna is particularly useful in locations where the erection of more conventional antennas proves difficult. RFI can often be prevented by changing the direction of the counterpoise.

The GP antenna need not be a straight piece of wire. There is a story—I can't vouch for its truth—that during World War II a clandestine operator in occupied Europe regularly sent out traffic using his bedspring for an antenna! In circumstances when it is not desirable to advertise one's presence, the GP antenna may often be disguised to look like something else. It may even be made of very fine wire, which is invisible from ground level (especially if the glint of the copper wire is removed by passing it through a candle flame). It can be folded or wrapped around an insulated tube such as a piece of plastic piping.

For portable or mobile use, a GP antenna has much to recommend it. Instead of feeding a whip by means of a coax, make a direct connection to the ATU and you have a portable/mobile antenna that can be made to resonate any part of any band. With a little care the GP, which is surely the simplest of all antennas, still has many uses. ■

The Care and Feeding of a Curved Linear Array Antenna System

For low cost, very low maintenance, yet acceptable performance, try this antenna system for use in high-frequency amateur radio operations.

This article documents the performance characteristics of a 39-element curved linear array (CLA) antenna. The system is fully tunable for all amateur bands, costs less than many other antennas (in fact, many hams already have one, if they only realized it), and presents several unique advantages, which we shall discuss later.

Design Considerations

The primary motive in designing this antenna system was aesthetic acceptability. Not necessarily mine, I hasten to add. To put it more clearly, I wanted to be able to do amateur radio without getting thrown out of the mobile home park I'm currently living in.

One highly desirable solution had, unfortunately, been eliminated by the removal of a large pine tree a couple of years before. Said conifer would have provided excellent camouflage for a multiband vertical.

An indoor longwire was tried briefly, but had a disturbing tendency of creating large amounts of rf inside a metal box (the mobile home). This solution was, therefore, quickly discarded.

Being newly upgraded and eager to get on the low bands after five years on VHF, I was desperate for an answer. Considerable discussion ensued among my ham friends about the project, much of it speculative at best. Given that I had a massive amount of aluminum at my immediate disposal, several friends suggested that I load up the mobile home itself. I quickly realized, though, that none of them had offered to be inside the house when this was attempted.

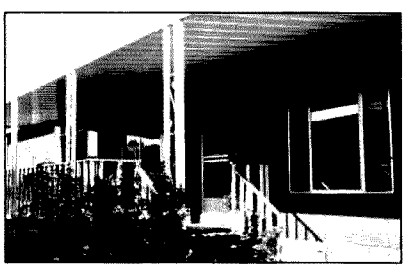

Photo A. The Curved Linear Array antenna, shown installed at the QTH of N6BIS.

". . . a rabbit living in a metal cage on the porch showed no ill effects from my DXing."

Finally, I threw the problem over to Bob Tarone WA6ZBX, who was willing to find the right solution for the situation. Hence his creation of the CLA, or "awntenna."

Specifications

The system we finally implemented is, essentially, a fat longwire. It consists of a 9 by 40-foot sheet of corrugated aluminum—in the common vernacular, a porch awning (see Photo A).

The term "39-element curved linear array" is a straightforward description of the antenna: there are 39 ridges in the aluminum sheet, each of them is curved (arched), and they are arrayed linearly with respect to each other. (There are also five smaller pieces of aluminum holding the thing up, but we try to ignore them.)

The awntenna is fed by a length of four-conductor copper wire (courtesy of Pacific Telephone) from an MFJ 901 tuner and a Heath 104A HF transceiver. (See Photo B.) Maximum PEP output from the Heath is 100 Watts; I have no particular desire to feed more rf than that into the awning.

The height above average terrain (HAAT) is about 9-1/2 feet. It is slightly higher on the side nearest the house, slightly lower away from it, creating a slope of approximately 5 degrees. The lengthwise dimension of the system is oriented almost precisely east-west.

The antenna is not in electrical contact with the house, so far as we can tell. A few short screws attach it to the wood paneling on the side of the house; evidently, they do not go through to metal. Two L-brackets which had secured the awning to the rain gutter were removed during original implementation of the system.

The five uprights are not electrically isolated from the antenna, but are insulated (via mylar booties and plastic bolts) from the cement into which they are bolted.

The awning also does not come in contact with the porch below it. This was proven conclusively in early tests, when a rabbit liv-

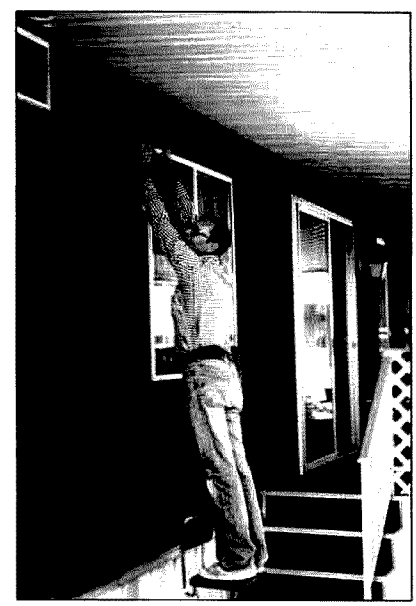

Photo B. Bob Tarone WA6ZBX hooks up the feed line for the awntenna.

ing in a metal cage on the porch showed no ill effects from my DXing.

The antenna is grounded with a short length of four-conductor wire (again courtesy of Pacific Telephone) to a three-foot ground rod driven into adobe earth. A 65-foot dual counterpoise (full-wave at 20 meters) was tried briefly, but discontinued when I discovered that keying up on 15 meters triggered the fluorescent lights in my slide-viewing table.

Total costs for the system were approximately $3(for the ground rod). I already had the antenna tuner and the feedline. Of course, I also already had the awning, saving me some $400 to $500 right there.

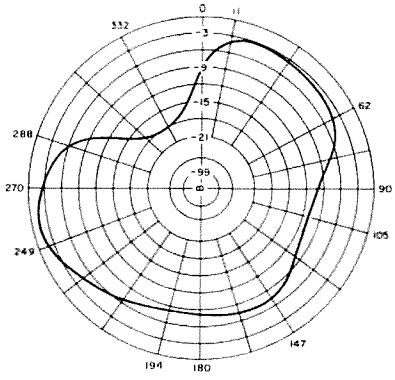

Fig. 1a. The predicted radiation pattern for the CLA.

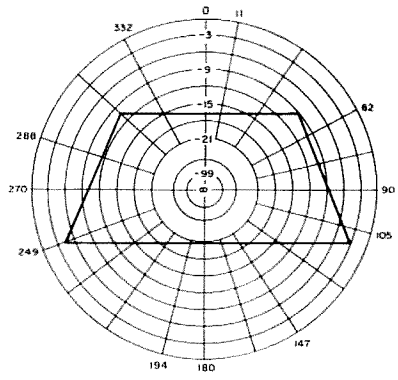

Fig. 1b. The actual radiation pattern for the CLA.

Performance

The CLA antenna has been successfully used on all standard amateur bands from 10 to 80 meters, and tunes quickly to 1:1 (or nearly so) on all of them. It does show a certain sensitivity on some bands, but on others it is nearly flat across the entire spectrum.

Due to this impressive performance, I only need one antenna, and therefore never have to worry about whether the correct antenna is in the circuit. I have been known to nab DX stations while friends were still switching antennas.

The predicted and measured radiation patterns for the system are shown in Fig. 1a and 1b. The pattern turned out to be a sort of casual cardioid, with a definite dip towards the north-northwest. This dip is probably caused by the signal going directly through the mobile home, although we're not certain.

As mentioned, the system points almost precisely east-west, but radiation measurements show no particular preference in these directions (or, for that matter, in any others). However, as of this writing, I have used it at 100W to work all 50 states and nearly as many countries. Signal reports tend to be only fair (typically 5/5-5/7), but, after all, DXCC certificates don't come with special endorsements for being 20 over 9.

Unfortunately, the system does lack pointability. Orienting it to a certain direction would involve rotating the entire house, which would subsequently result in major problems—especially with the neighbors. On the other hand, I never have to worry about which way my antenna is pointed, since I have no choice in the matter. I can concentrate on calling while others are still fussing over great-circle maps.

Polarization, direction of current, and phase relationships in different parts of the system have not been measured. Neither, unfortunately, has gain, since I have been unable to move the antenna to a proper testing facility for precise analysis. However our guesstimates put the gain somewhere between −3 and 0 dB.

Additional Benefits

The CLA antenna requires no maintenance, aside from occasionally sweeping the leaves out of it. In fact, no adjustments are *possible*, a boon to those of us who like to just hook up the equipment and go—although admittedly frustrating to those who feel obliged to tinker with their amateur radio gear.

Since there are no moving parts, there's really nothing that can fail. I never have to worry about my rotor dying with the antenna pointed south just as JY1 comes on the air. (Of course, I probably won't even *hear* him anyway, so I won't suffer by knowing what I'm missing.)

The system has the additional advantage of providing shade on hot days—a benefit that hams with much more expensive (and supposedly better) multi-element beams certainly cannot claim.

Backup system

In case my primary antenna should ever fail (i.e., fall down), a backup system is kept nearby (see Photo C). This system is a verted vee, a variation on the more common inverted vee. Informally, this type of antenna is known as "rabbit ears."

One problem with the verted vee is the exceedingly high capacitance between the elements; it's evident that the phrase "dumb bunny" was not created haphazardly. On the other hand, the high density dielectric results in a high amount of capacity loading, thus accounting for its ability to resonate even on 75 meters despite its apparently short element lengths.

Unfortunately, the verted vee system is more appropriate for mobile operation. It is, in fact, *overly* mobile, and keeping it connected to the radio presents considerable difficulties. Luckily, I have never had to use it.

Possible Improvements

Although the CLA system has been working very satisfactorily, several uninvited suggestions have been made for improving it.

The most obvious is to hook together all the mobile home awnings I possibly can, to provide an effectively larger antenna. With some 800 homes in this park alone, and three similar parks nearby, the prospects are truly awesome (or awful, as the case may be). Better yet, of course, would be a system that allowed connection of different houses at will to create the optimum pattern for reaching each target station.

Currently, the antenna is corner-fed. There has been some speculation on whether center feeding would favorably affect the radiation pattern. Since there is very little literature on feeding awnings (other than that they like a little roughage occasionally), any expert comments on this would be welcomed.

Summary

We have considered the design and performance characteristics of a 39-element curved linear array (CLA) antenna system for use in high-frequency amateur radio operations. We have found that this system offers low cost, very low maintenance, and yet acceptable performance.

Exact technical specifications, costs, and installation instructions for this antenna are not available from the author, but may be obtained from Sears Roebuck and similar vendors.

My gratitude in preparing this article goes to Bob Tarone, WA6ZBX, for the antenna concept and construction; to Kit Blanke, WA6PWW, and Glenn Thomas, WB6W, for their assistance in performing the radiation pattern measurements; to Stephen Greenberg, for coining the term "curved linear array;" and to all of the above for contributing valuable jargon with which to properly obfuscate the subject. ■

Stacked Vee-Beam Arrays

If 15 meters sounds dead, you're not using the right antenna!

I am constantly surprised at the number of retired people who have moved to the warmer climates, particularly in the Caribbean area, who use amateur radio to keep in touch with relatives and friends back in the old home town. Most of these people, relative newcomers to ham radio, are not technically sophisticated in the art of antenna design, are limited in income, and depend on inefficient vertical radiators to maintain daily communication.

Many of these hams have sufficient space in which to install a low-cost wire antenna that will give greatly improved performance on both transmitting and receiving. The vee beam for 15 meters, believe it or not, does not require a site in the Sahara Desert to be effective. Besides, a vee system that will double or quadruple your effective radiated power can be built for less than the price of a dinner for two in a good restaurant. Interested? Read on.

Basic Vee Beam Array

The vee beam antenna, originally called the RCA Model D array, is one of the oldest directional antenna systems still in use on the shortwave bands. It was designed originally for commercial overseas radiotelephone service long before the advent of the yagi and other compact arrays. While a vee beam for 40 or 20 meters requires a large area to obtain a high degree of gain and directivity, a similar array for 15 or 10 meters isn't excessively large. For the higher frequency bands, a vee will provide worthwhile gain and directivity even when the legs are as short as two wavelengths, and you can still get some gain when the legs are as short as one wavelength long. The main disadvantage of the short vee, besides having less gain, is that it can't be used with good results on more than one amateur band.

For a frequency of 21.3 MHz, the length of a one-wavelength leg is 45 feet, 4 inches. Two wires in the vee arrangement will produce a bidirectional gain of about 2.1 dB over that of a horizontal half-wave dipole operated under the same power and height conditions. In this case, the apex angle should be 90° for best results. For legs two wavelengths long, the gain rises to about 5.5 dB, and the apex angle is reduced to 70°. For legs three wavelengths long or longer, refer to Table 1.

SPECIFICATIONS FOR 21.3 MHz

WAVELENGTHS	LEG LENGTH (FEET)	APEX ANGLE (DEGREES)	DIMENSION D (FEET)
1	45.04	90	63.7
2	91.24	70	104.67
3	137.44	58	133.26
4	183.63	50	155.21
5	229.83	45	175.90
6	276.03	40	188.81
7	322.23	38	209.67
8	368.42	35	221.60
9	414.61	34	242.44
10	460.81	32	254.033

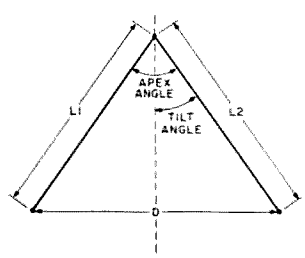

Table 1. Important dimensions of vee beam antennas.

In the absence of tabulated data, the apex angle can be made equal to twice the lobe angle of a single wire of the same length. To roughly determine the gain of the vee beam, compared with a longwire of the same number of wavelengths, add 6 dB to the gain of a single leg operated alone when the leg length exceeds two wavelengths. Thus, a longwire antenna five wavelengths long will have a gain of about 4 dB in each of its major lobes. If two such longwires are used in the vee configuration, you add another 6 dB and the bidirectional gain rises to 10 dB. A gain of 10 dB represents an effective transmitter power increase of 10 times. Thus, the 100 Watts rf output power from your Japanese transceiver is effectively raised to 1000 Watts. The estimated vee antenna power gains listed in Table 2 are conservative.

"Steerable" Vee Beam Design

The greatest advantage of the yagi antenna over a large wire array, such as the rhombic, curtain, or vee beam, is, of course, its compactness and the fact that it can be rotated over 360°. The fixed array is most useful for working into a given area, such as Europe or Australia, and is ideal for the retired or disabled ham who works the same station day after day. The two lobes of a vee beam having legs several wavelengths long are comparatively narrow, and the line of the apex bisector must be oriented accurately with respect to the distant station.

Antenna Lengths (Wavelengths)	Power Gain (dB)
1	2.10
2	5.50
3	7.00
4	8.00
5	8.75
6	9.50
7	10.25
8	10.75
9	11.25
10	11.70
11	12.00
12	12.25

Table 2. Estimated power gain of vee antennas with leg lengths of 1 to 12.

The array I'll describe here is designed so that the direction of the apex bisector may be shifted in azimuth by about 15° to 20°. This arrangement allows the center of the lobe (apex bisector) to be laid "dead on" the distant location. The rope and pulley arrangement also allows the apex angle to be adjusted accurately with a field-strength indicator to obtain optimum gain.

My W6TYH vee beam is suspended from three large oak trees that nature was kind enough to grow as the corners of an equilateral triangle about 120 feet on a side. It was decided to make each leg of the vee two wavelengths long. Referring to Table 1, a leg two wavelengths long is 91 feet, 4 inches, and the apex angle for a vee with two wavelength legs is 70°. The bidirectional gain is about 5.5 dB, about the same as that of a two-element yagi on a high tower.

To determine distance D between the ends of the two legs at the base of the vee (open end), the ratio of 0.5D to the leg length, L, equals the sine of the tilt angle, T. As shown in Table 1, the tilt angle is equal to one half the apex angle. Thus, for a vee array with a leg length of two wavelengths, the tilt angle will be 70°/2 or 35°. Proceed as follows:

sin T = 0.5 D/L

sin 35° = 0.574 = 0.5 D/91.3

Therefore, 0.5D = 0.574 x 91.3 = 52.4062 = 0.5D, then D = 52.4062 x 2 = 104.81 feet or 104 feet, 9 inches.

The dimension D for vee arrays with longer leg lengths is calculated in the same manner. This data is included in Table 2.

To orient your vee beam accurately so that the apex bisector points to the distant spot on the globe, you should lay out a true north/south reference line through the center of your antenna site. Later, in the section covering the adjustments of the array, I'll tell you how to lay out the reference line and use it to orient the antenna.

When I was setting up the W6TYH antenna, I discovered that the apex end of the proposed vee beam and one tree were on a line precisely east and west. To project the apex bisector line (lobe center) directly on Europe and Australia, the apex bisector should be oriented about 15° north of east and south of west, respectively. To do this, I decided to support the open end of the vee from a 1/4-inch nylon rope stretched between the two farthest (base) trees.

Currently, my array is oriented directly on Sydney, Australia, and is pulled up to a height of about 23 feet above the ground. I work into both Europe and the South Pacific with excellent signal strength reports. Later, I hope to add another vee section in a stacked configuration for still greater gain.

Very High-Gain Vee-Beam Design

The gain of a vee beam antenna system may be increased by any one or all of the following:

(1) By making each leg longer in wavelengths;

(2) by stacking two arrays, one above the other; and

(3) by placing another identical vee array in front of or behind the one and driving one array 90° out of phase with the other.

In the last case, the radiated pattern will be unidirectional and the gain will increase by 3 dB. The following comments apply particularly to methods 2 and 3.

First, concerning the stacked vees, the top vee must be at least one wavelength above ground (about 45 feet for 21.3 MHz), with the second vee placed directly under it. The spacing between the top and bottom vees is one half wavelength (free space), with the lower vee at least 23 feet above the ground for 21.3 MHz. The apexes of the two vees are connected to the two ends of a half-wavelength open-wire line made from two No. 14 copper wire conductors spaced about 4 inches on centers. The right leg end of the upper vee conductor must connect to the same open-wire conductor that is connected to the right leg end of the lower vee conductor. In other words, the upper and lower vees are operated in phase with each other.

Notes: Step 1—Make longitudinal time correction first (see text); Step 2—From selected date, determine number of minutes seasonal time correction required (see text); Step 3—Add or subtract seasonal time correction (minutes in right-hand column) to or from longitudinal time correction; Step 4—Add total to local legal or official time (EST, CST, MST, or PST).

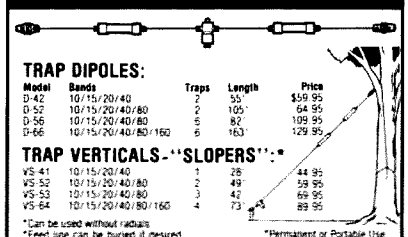

Table 3. Seasonal time-correction chart.

Materials	Cost
250 feet No. 14 plastic-covered electrical wire, copper, at .05 per foot	$12.50
Two 6" insulators; 1.00 each	$2.00
300 feet ¼" nylon rope; .80 per foot	$24.00
Three pulleys for ¼" rope; .90 each	$2.70
3 feet, ¼" copper tubing for L1; .40 per foot	$1.20
C1 from junk box (old BC radio tuning capacitor will be suitable)	
Miscellaneous	$1.00
	$43.40

The above cost is an estimate if everything is purchased. The W6TYH array actually cost less than $25 since some of the material was on hand.

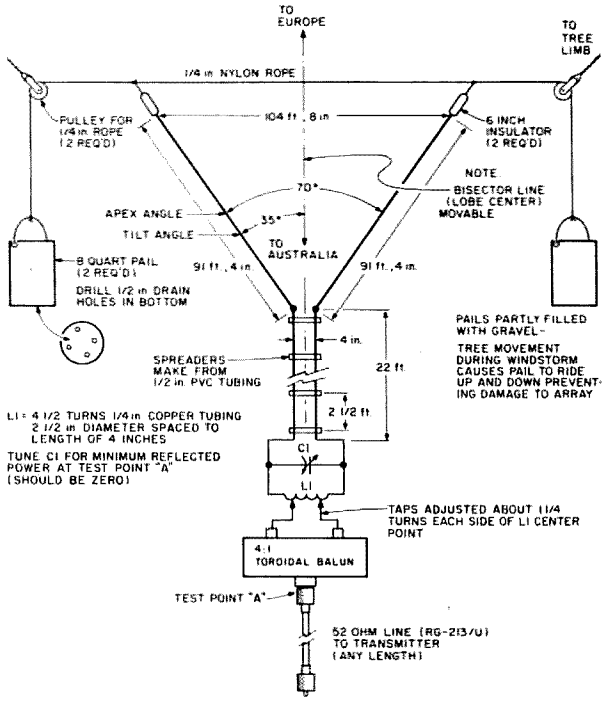

Fig. 1. W6TYH vee beam for 15 meters.

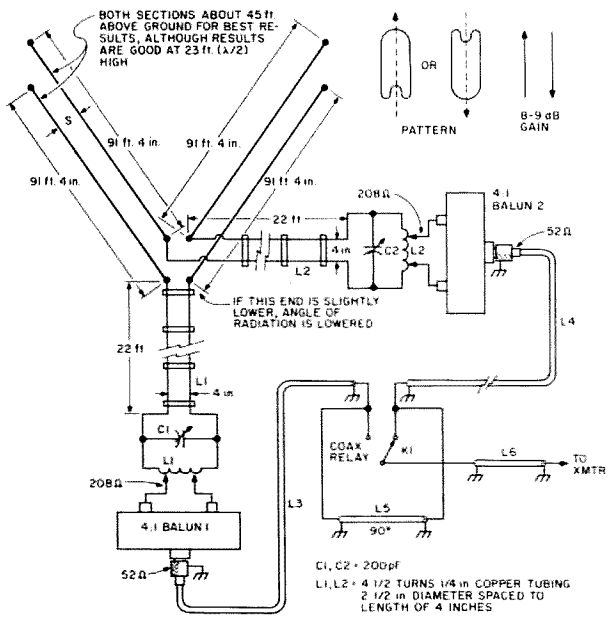
The interconnecting open-wire line is referred to as a phasing line. To ensure that the two sections of the array, upper and lower, are driven in phase and receive equal-amplitude rf currents, the feedpoint for the system should be located at the center of the open-wire phasing line, positioned a quarter wavelength away from the apex feedpoint of each vee section.

To the center feedpoint of the phasing line, connect another identical open-wire line but only one quarter-wavelength long. This quarter-wavelength line plus the quarter wavelength of line from the apex feedpoint of each vee section down to the phasing line feedpoint will be equal to a distance of one half a wavelength and will cause the open end of the second quarter-wavelength line to appear as a high-impedence point. To feed a high-impedance point on a line, you need a parallel-resonant tuned circuit. Such a circuit is useful for resonating the system and for matching the feedpoint to a 52-Ohm coaxial cable transmission line back to the transmitter.

Vee Beam Adjustments

The vee array, singly, stacked, or excited in quadrature, is virtually foolproof. If you follow the dimensions and instructions given here the array won't fail to perform with good results. For maximum performance, all dimensions and adjustments should be made as accurately as possible.



The exact leg lengths are not extremely critical for a given frequency; the exact lengths specified here have been pruned to allow you to use the array over a bandwidth of about 200 kHz without having to retune the coupling circuit at the antenna or change the loading at the transmitter. The longer the leg lengths, the less critical the adjustments with respect to a change in frequency.

Once the array has been installed, connect the two output terminals of the 4:1 impedence ratio toroidal balun transformer at points about one or two turns each side of the L1 center point. Connect an swr (reflected power) meter in series with the 52-Ohm line and the coaxial input terminal of the balun (Test Point A in Fig. 4). Set the meter selector switch on F (forward), and turn the indicator sensitivity control all the way off. From the transmitter, apply an unmodulated carrier signal of about 5 Watts or less, and of the correct frequency, to the 52-Ohm line. Adjust the swr meter sensitivity control until the indicator pointer reads exactly full-scale forward. Now, throw the meter selector switch to indicate reflected power (R). Quickly rotate C1 for the lowest meter indication ("null" or "dip"). If you can't bring the indicator pointer to zero, move the balun tap connections away from or closer to the center of L1.

When the tap connections are correct and the indicator pointer reads zero by adjustment of C1, the 52-Ohm line will be "matched" through the balun to the 208-Ohm balanced feedpoints on L1. At the transmitter, the line should "match" the transmitter 50-Ohm output impedence without having to use an antenna "tuner." The transmitter output circuit should load normally to the rated output power level.

Field Strength Adjustments

To adjust the array for maximum gain (field strength), I used a portable, battery-operated solid-state short-wave receiver. The General Electric Model 7-2990A or equivalent is ideal for this purpose. The GE receiver is equipped with a digital-readout frequency

Notes: (1) S = 0.25. L1-L2 = openwire line, #14 copper spaced, 4". *L1 must be exactly same length as L2.* (2) L3-L4 = RG-213/U or RG-8/U coaxial lines. *May be any length but must be exactly the same length.* (3) L5 = RG-213/U or RG-8/U. L = 162.36/f where f = frequency and L = feet. For 21.3 MHz, length of RG-8/U or RG-213/U = 7 feet, 7½ inches. (4) Unidirectional pattern may be switched in either of two directions along apex bisector line. Gain over dipole approximately 8–9 dB. (5) Adjust taps on L1 and L2 for zero reflected power at test point A. Adjust each section individually as per text and then recheck entire system in operation. Trim minor adjustments of C1 and C2 as required.

Fig. 2. Endfire vee beam for 15 meters.

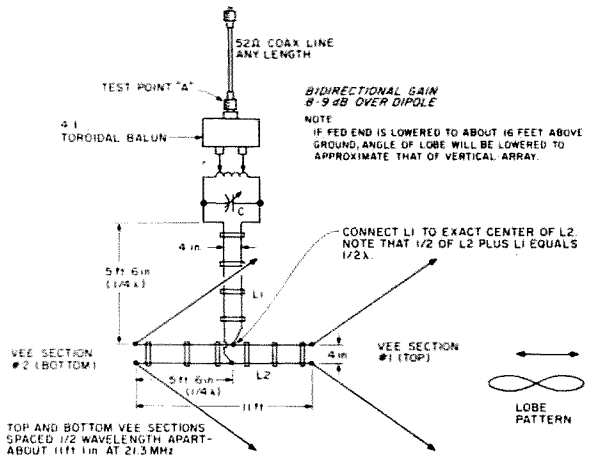


Fig. 3. Stacked vee beam array for 15 meters.

indicator, accurate to about 1 kHz, and a signal-level meter (not a calibrated S meter). In order to adjust the array for maximum field power, I placed the little receiver about a mile away from and directly in front of the antenna, and varied dimension D for maximum signal-level indication. The increase in the field strength was barely perceptible, but it was satisfying to know that the array was in optimum adjustment.

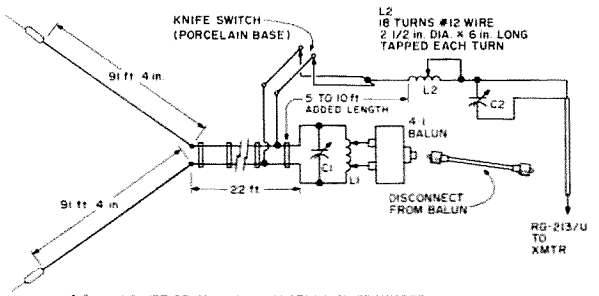
Vee Beam Unidirectional Operation

When two vee arrays are arranged one behind the other, spaced a quarter wavelength apart, and driven 90° out of phase, the pattern will be unidirectional with maximum radiation in the direction of the array with the lagging rf current. The directional characteristics will be "end fire," but the radiated lobe pattern will be much sharper than the pattern obtained from vertical-phased arrays. Although I haven't calculated or measured the pattern from a double-vee phased array, the rear of the pattern, along the apex bisector line, should be highly suppressed with the usual cardioid notch resulting in a high front-to-back ratio. The phasing control circuit shown can be used to reverse the direction of maximum radiation by 180°. The unidirectional gain of the phased vee system will be about 3 dB greater than that of a single bidirectional array. The directional system is controlled remotely by means of relays and miniature toggle switches.

Terminated Vee Antennas

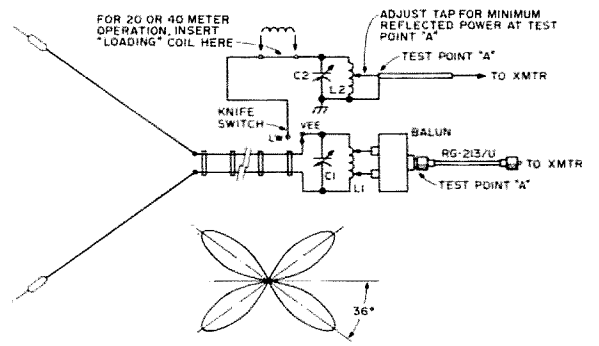
To make a vee array unidirectional, each leg may be terminated at its far end with a non-inductive resistor of about 400 to 800 Ohms. The terminated-vee radiation pattern is practically unidirectional in the direction of the terminated ends. The terminating device should be capable of dissipating one-third of the rated transmitter rf power output. It may be made up by connecting a number of 2-Watt carbon resistors of suitable values for the termination.

In actual practice, the terminating resistor values are adjusted for minimum standing waves on the transmission line. It's usually necessary to try different values and repeat the procedure at different frequencies throughout the amateur band in order to obtain the optimum resistance value. An insulated counterpoise wire may be connected across the open end of the vee to act as a ground for the termination. The terminating resistor is connected from the end of the vee conductor to the ground wire. Do not connect the ground wire directly to the vee leg conductors.



Orientation of Vee Beam Antenna

Radio waves travel from one point on the earth's surface to another by way of a great circle route. To produce the greatest signal strength at the distant receiving point, the front of the antenna field pattern must be aimed in the great circle direction of the receiver. The first step in the orientation procedure is to establish a true north/south reference line through the antenna site.



There are several methods that can be used to determine the direction of true north. If you have a good quality magnetic compass it will indicate the direction of the north magnetic pole. However, since the magnetic poles of the earth "drift" constantly, the compass indication must be corrected for any given time. You can usually obtain the amount of correction by calling your city or county surveyor's office or by contacting a civil engineering organization. For ages, the North Star has been used to determine the position of the north geographic pole. Today, however, due to air pollution, especially near large cities, it may be difficult to locate the North Star. There is another method—the use of the sun at true noon—that is very accurate and can be used on any day of the year when the sun shines.

At exactly noon (sun or standard time), at any place on earth, the sun bears due south in the Northern Hemisphere and due north in the Southern Hemisphere. Therefore, at high noon the shadow of a vertical pole or suspended vertical line is pointing due north in the Northern Hemisphere or due south in the Southern Hemisphere.

To precisely locate true north or true south, you must use a very accurate timepiece, preferably synchronized with time signals from WWV. The time indicated for noon must be corrected first from your antenna site location and second for the day on which the siting is accomplished. When these two corrections are applied, the resultant time is

"A"- USING VEE BEAM AS 1/2λ ANTENNA ON 75 METERS

"B"- USING ONE LEG AS 15 METER LONG WIRE FOR NON-DIRECTIONAL ANTENNA EACH OF FOUR LOBES HAS ABOUT 2 dB GAIN. ALSO OPERATES ON 20 OR 40 METERS USING LOADING COIL

Fig. 4.

exactly solar noon, and the shadow of a vertically suspended line will be in the exact north and south position.

To correct your standard time for your location, consult a globe or an atlas to determine the longitude of your antenna site. An accuracy of about 15 minutes of longitude will be sufficient. The time correction to be applied is equal to one minute of time for each 15 minutes of longitude, or 4 minutes of time for each degree of longitude. The amount of correction will be determined by the difference in longitude between your antenna site and the particular meridian of longitude on which your local standard time is based. In the U.S., local EST is based on the 75th (75°) meridian of longitude, local CST is based on the 90° meridian, local MST is based on the 105° meridian, and PST is based on the 120° meridian. The 120° meridian passes through Nevada, a few miles west of Reno. The W6TYH antenna site is located on the 121° meridian of longitude; I'll use that location as an example.

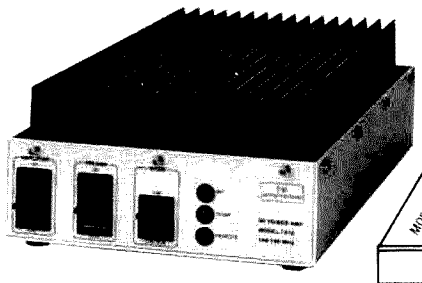
Standard times (EST, CST, MST, and PST) are legal or official times but are not necessarily solar or sun times. For example, on June 16th of any year, at 12:00 noon local standard time on any time-base meridian, the sun will be directly overhead and the local standard time and the solar time will be the same. However, for a site located west of the time-base meridian, true solar noon will occur at a time earlier than the legal or official time noon.

For example, W6TYH is located west of the PST time-base meridian (120°). Therefore, on June 16th of any year, true solar noon will occur at the W6TYH antenna site at exactly 12:04 p.m. PST, since I must add 4 minutes for each degree of longitude. If the antenna site had been located on the 119° meridian, east of the time-base meridian, I would have had to subtract 4 minutes, and true solar noon would have occurred at 11:56 a.m. PST (actually 12:56 MST, because the 119° meridian lies within the MST zone). This time correction is referred to as longitude time correction.

The orbit of the earth around the sun actually is not a circle but an ellipse. You must add a second correction because of the varying motion of the earth in its orbit with respect to the sun. The necessary corrections for various dates throughout the year are calculated and presented in Table 3. When the correction is preceded by a plus sign, the correction should be added to the local standard time. When the correction is preceded by a minus sign, the correction should be subtracted. This time correction is referred to as seasonal time correction.

To illustrate the use of both the longitude and seasonal time correction, let's assume that the date on which the observation is to be made is June 26th of any year. Referring to Table 3, the seasonal time correction for this date is found to be plus 2 minutes. Since you must add 4 minutes for longitudinal time correction and another 2 minutes for seasonal time correction (for a total of 6 minutes), the exact instant of true noon will occur at W6TYH on June 26 of any year at 12:06 pm PST. Note that all local times are standard and not daylight-saving time.

Now that the preliminaries have been taken care of and you have determined the exact time of true solar noon at your antenna site, you can use this information to lay out a true north and south reference line through your antenna site—from there you will be able to determine accurately great-circle path directions to any point on the earth. The accuracy with which you are able to predict the point on the globe where your antenna field will be maximum will depend largely on your skill in laying out the reference lines through your antenna site and on a great-circle map or globe.



For the next step, you'll need a perfectly straight piece of pipe about 6 to 10 feet long. At the center of the antenna site, dig a hole about 10 or 12 inches deep. Stand the pipe in the hole and fill the hole with soil, tamping it to hold the pipe upright; check it with a carpenter's level to make sure that is it absolutely plumb (straight up and down). Tie a nylon cord around the pipe and stretch it out about 10 to 20 feet to the north. Watch the time, and at the exact instant of true noon, drive a rod or stake into the ground at the end of the pipe's shadow. Stretch the cord from the pipe to the top center of the stake. The cord is now stretched along your true north-south line.

If you have followed these instructions carefully, this line will point to the geographical poles of the earth with an accuracy within a few degrees. The line may be projected in each direction as far as you desire. Once established, a true north-south reference line is permanent and will always point to the geographical poles of the earth.

Since great-circle maps are not usually available for specific locations, use a globe for the next step. A low-cost student's globe made from pressed cardboard is best for this purpose. These globes have a center post at each geographical pole. Tie one end of a white thread around the north pole center post, dress it down over your location, wrap it around the south-pole center post, draw it taut and secure it in position. Stick a straight pin in the globe at your antenna location.

Stick another pin in the globe at the distant point to which you wish to transmit your signal. Stretch another thread between the two pins representing your antenna site and the distant receiving point. With a protractor, measure the angle of the bearing between the true north reference line (thread) and the line from your location to the distant receiver. Transfer the data obtained from the above measurements to the actual north-south reference line through your antenna site and determine the direction of the apex bisector line of your vee beam accordingly. ■

DESIGN EVOLUTION IN RF P.A.'s

Now with GaAs FET Preamp

- Linear (all mode) RF power amp with automatic T/R switching (adjustable delay). Amplifier useable with drive powers as low as ½ watt.
- Receive preamp option, featuring GaAs FETS (lowest noise figure, better IMD). Device NF typically .5 dB.
- Thermal shutdown protection incorporated
- Remote control capability built-in
- Rugged components and construction provide for superior product quality and performance
- All models include a complete operating/service manual and carry a factory warranty on all components
- Designed to ICAS ratings, meets FCC part 97 regulations
- Approximate size is 2.8 x 5.8 x 10.5" and weight is 5 lbs.

The Match Maker

Everyone knows that antennas and transmitters should "match." But what exactly is that? And how is it achieved? Here are the answers.

Calvin McCarthy VE3LMP
98 Windsor Street
Thunder Bay, Ontario P7B 1T7
Canada

The need to find the "perfect match" is all-pervasive in life. The mechanic must fit a bolt to its matching nut. The worried mother strives to match her wonderful daughter with the perfect husband, and the radio amateur tries to create the perfect match between his exciter and amplifier, between his amplifier and his transmission line, and between his transmission line and antenna.

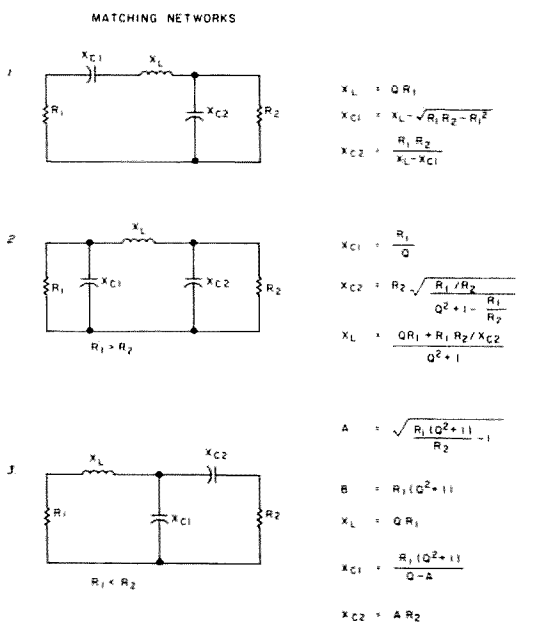

Fig. 1. These matching networks can be used to provide a match with maximum power transfer between unequal resistances.

What is all this concern about the perfect match? The mechanic's concern is obvious. None of us would suggest trying to fit a coarse-threaded bolt to a fine-threaded nut. Comments about the mother's concerns are best left to advice to the lovelorn, so we will discuss the concern of the amateur and leave mother to her fears.

Why Matching?

First we will discuss the reason for considering the matching problem. Efficiency of operation is always a concern. Why use more power than necessary to get the job done? There is a rule in electrical theory which says that you get the most energy into the job to be done (maximum power transfer) when the resistance of the source of the energy (signal generator) is equal to the resistance of the job to be done (load).

You can easily verify this with a few calculations. In Fig. 2 you see calculations done for a 10-volt generator with a resistance of 10 Ohms. As you look at the power-output figures, you will observe that the output power peaks at 2.5 Watts. Also observe that this occurs when the load resistance is equal to the generator resistance. If you are quick, something else will have crossed your mind. With maximum power transferred to the load, there is the same amount of power dissipated in the generator resistance. Only 50 percent of the power from the generator has reached the load. The other 50 percent has been lost as heat in the generator.

How is this important to us? If we are creating a signal in a generator, a vfo, a transmitting exciter, a kilowatt amplifier, or in a transmission line and we want the maximum power supplied to the load, we must make sure that the equipment which is supplying the energy has the same output resistance as the load resistance. For example, if your transceiver has an output resistance which looks like 50 Ohms, then to get maximum power transferred into the input of your kilowatt, the input resistance of the kilowatt must look like 50 Ohms as well.

Fig. 3 illustrates the idea. V_{gen} is the signal created by

GENERATOR RESISTANCE 10Ω
INPUT VOLTAGE 10V

POWER IN LOAD = $(I_{LOAD})^2 R_{LOAD} = \left(\frac{V_{IN}}{R_{GEN} + R_{LOAD}}\right)^2 R_L$

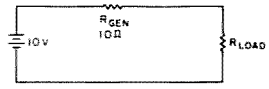

Fig. 2.

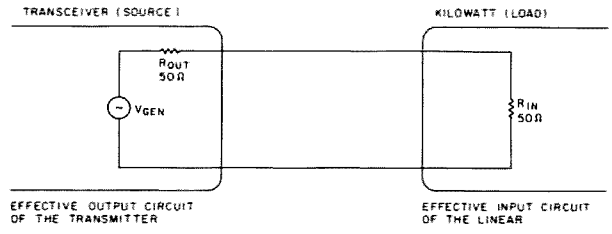

Fig. 3.

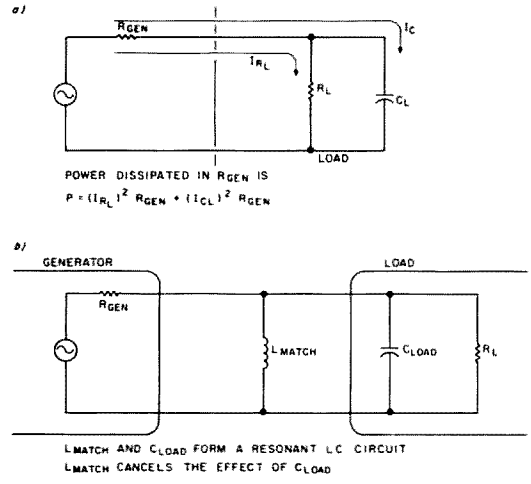

Fig. 4.

the final amplifier of the transceiver and R_{out} is the *equivalent resistance* of the same circuit. If you went into your final amplifier you would not find this as an actual resistor, but the circuitry which is there can look as though it were exactly a single resistance. Looking at the kilowatt input, the R_{in} is not an actual resistor either, but all the circuitry attached to the input looks like this single resistor if all you can do is measure it at the input terminal.

Another place where this is important is at your antenna. If your antenna terminals (the load) look like 75 Ohms to the signal generator (the output of your coaxial transmission line), then to get maximum power into the antenna the transmission line must look like 75 Ohms where it attaches to the antenna.

The perfect match we are thus looking for is a condition where the signal generator appears to have the same resistance as the load. This gives the desired maximum power transfer.

Loads With Inductors and Capacitors

If all circuits were resistive, then the matching problem would be reasonably simple. In radio-frequency circuits, however, we find capacitors and inductors as well. How do they affect our perfect match? An inductor or capacitor does not dissipate energy. All either of these does is absorb energy, then release it again later at a time when it is inconvenient.

Consider the loads of Fig. 4. They contain a resistor which will dissipate energy (do work) and a capacitor which accepts current from the generator and then puts it back into the system at a later time. This current, I_C, which flows through C must flow through R_{gen} as well, where R_{gen} dissipates energy ($I_C^2 R_{gen}$). This is energy lost without any work being seen for its loss. Remember how with just a resistive load energy was lost in the generator resistor as well, but at least some work was gained. This loss was acceptable but the losses created by the current through the capacitor are not acceptable.

The unacceptable loss of energy through the capacitor current (and the same thing would result if the capacitor were changed to an inductor) suggests that this reactive component should be removed from the circuit. This component may, however, be fixed in the circuit and not removable. Is a match possible with this situation? Yes, we can use our knowledge of resonant LC circuits to neutralize the effect of the reactive component.

If a capacitor, inductor, and resistor are combined to create a resonant circuit at the frequency where the reactance of the capacitor is equal to the reactance of the inductor (resonant frequency), the circuit will look to the generator as though this were only a resistive load. The current flowing in the capacitor would be cancelled by the current in the inductor and the only current flowing through the R_{gen} would be resistive current.

The circuit of (a) in Fig. 4 is not desirable for maximum power transfer, yet neither the generator box nor the load box can be modified. Consider now (b) in Fig. 4. A match has been created by attaching L_{match} in parallel with the load to cancel the effect of C_{load}. Now a condition where maximum power transfer is possible has been created.

This expands our condition for maximum power transfer to say that the generator resistance must be equal to the apparent load resistance and any reactive component in the generator must be matched by the opposite reactive component in the load ($2\pi fL = 1/2\pi fC$).

Different Output and Input Impedances

If this were all there is to matching, it would be an elementary problem. Life is never so simple, however. Matching involves providing a maximum power transfer from a generator of maybe 5 Ohms to a load of 50 Ohms. This is the problem of matching a power-transistor collector to a coaxial transmission line. To get the maximum power transfer out of the transistor, the transistor must be driving a load of 5 Ohms. But the load is 50 Ohms! To get maximum power transfer into the 50-Ohm load, the load should think it is being driven by a 50-Ohm generator. Our generator is only 5 Ohms! How are these two incompatible impedances reconciled?

The LC matching network

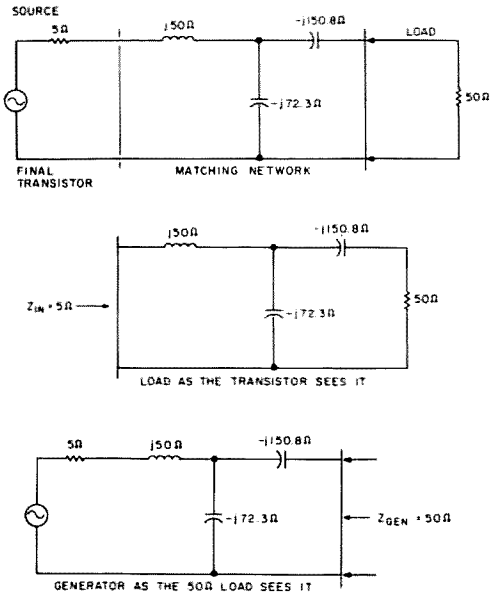

Fig. 5.

is able to reconcile these two impedances without a loss of energy in the conversion. Fig. 5 shows one possible matching network and its effect on the circuit. We will argue that the generator is the final transistor of a power amplifier. The LC network is the matching network. The load is a 50-Ohm coaxial cable feeding a 50-Ohm antenna. The transistor thinks its load is the combination of the matching network and the 50-Ohm coaxial cable. This apparent load looks like a 5-Ohm resistor at the frequency of operation. To the 50-Ohm transmission line, the matching network and transistor together appear to be its generator, and this combination looks like a 50-Ohm source resistance. The matching network has provided the impedance transformation so that the source (the transistor output) has the load it desires while the load (the 50-Ohm transmission line) has the generator it expects for maximum power transfer.

Your Place in All This

Can a radio amateur use this matching theory? You use it every time you tune your final, dipping the plate current and increasing the load coupling. Dipping the plate is effectively adding reactive impedance to the tuned circuit to cancel the opposite reactance which is in the circuit. Increasing the load coupling is bringing the effective load impedance to equal the effective source impedance.

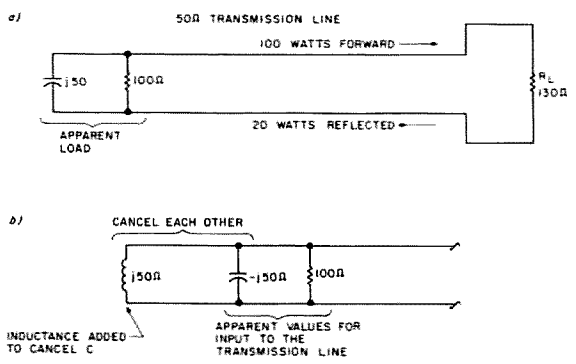

Fig. 6.

Transmission Lines and Matching

The problem of the perfect match also rears its head in transmission lines and antennas. It is desirable to get a maximum percentage of the generated power to the antenna.

Transmission lines such as a coaxial cable are very interesting components. If the cable is one thousand miles long, then its input terminals look like a resistor. A generator attached to this input appears to have a resistor for a load. Now if the cable is much shorter, more like the length we would use, but the far end of the cable is terminated in a resistor equal to the resistance which the very long cable looks like (the characteristic impedance of the line), then the input would still look like the same resistor. All energy put into the coax would travel down the coax and be used in the termination resistor (load).

But now the interesting phenomenon! If the load at the far end of the transmission line is not equal to the characteristic impedance of the line, all of the energy put into the input would travel down the transmission line but not all of it would be absorbed by the load at the far end. Some of the energy is reflected—sent back the way it came. Here we do not have maximum power transfer. All of the energy is not used in the load. Some of it travels back to the transmitter again, and now the transmission line becomes a signal generator with the reflected signal as the signal and the transmitter output device becoming the load. This returning energy would be used to heat the plate of the final or heat the transistor heat sink.

What if you have a high vswr on your transmission line and 20 Watts is sent back from the load which was sent 100 Watts by the transmitter? How can you protect your finals from this vswr of 2.6? Fig. 6 shows a possible situation which could cause this. The antenna with its impedance of 130 Ohms is connected to the 50-Ohm transmission line. For reasons explainable by transmission-line theory, we will say for our example that the input end of the transmission line looks like a resistor of 100 Ohms in parallel with a capacitor of 50-Ohm capacitive reactance. This near-end impedance is the load presented to your transmitter.

The transmitter connected to this point cannot tell the difference between the end of the coax and a real resistor and capacitor of our example value. Again we use a matching network as our solution. The effect of the capacitance can be cancelled by using an inductor to make a resonant circuit. Fig. 6 (b) shows this inductor added to make the input look like a resistor only. Now we have a resistive load which will accept power without causing extra final heating.

Tube Final Match

If your transmitter has a tube final, its pi network will be able to convert this 100-Ohm apparent resistance to the tube output impedance while adding the necessary inductance to cancel the capacitance. Fig. 7 shows a pi-network solution (network 2 in Fig. 1) which creates this match from our transmission line to a 1000-Ohm tube output. Notice that X_{C2} in Fig. 1 is made of two capacitors. One is the transmission line's apparent capacitance and the other is a real capacitor found in the matching network. Looking into the network where it attaches to the coax, the network would look like 100 Ohms of resistance in parallel with a 50-Ohm inductor. We have a good match to our coax input and it cancels the capacitance of the load.

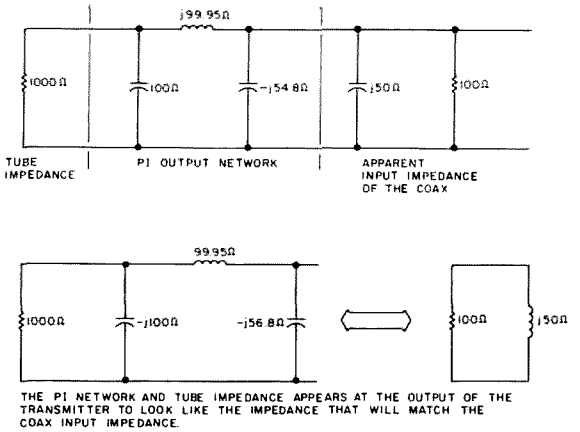

Fig. 7.

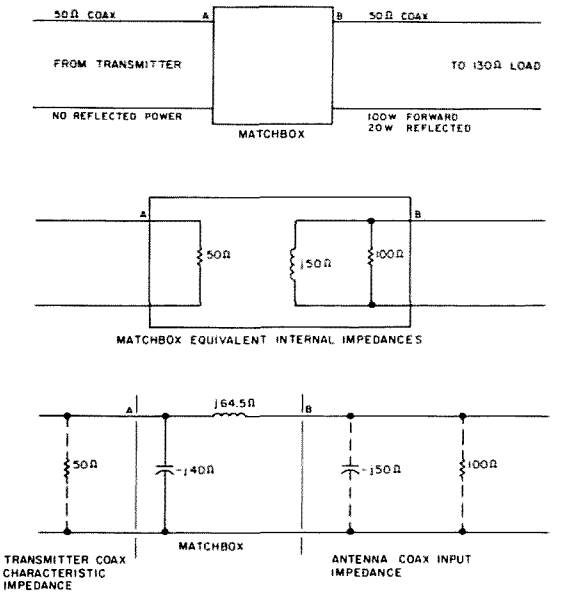

Fig. 8.

Transistor Final Match

For the modern amateur, this pi-network solution is not possible. Solid-state final transistors have an output impedance of maybe 1 Ohm and broadband transformers are used to transform this to an output impedance of 50 Ohms. The solid-state power amplifier must have a 50-Ohm load presented to its output by the transmission line. We will still consider our same problem and see how we can create a desired match with an antenna tuner or matchbox.

Fig. 8 shows the desired situation. The 50-Ohm coax from the transmitter must be terminated in a load at A which looks like 50 Ohms. This will make the transmitter see no reflected power. The 50-Ohm coax going to the antenna must see an impedance at the output of the matchbox which matches the 100-Ohm resistance in parallel with the 50-Ohm capacitance appearing at its input. This will give our desired maximum power transfer into the antenna transmission line.

An L network will provide the conditions to match both transmission lines effectively. If we could measure the impedance looking into port A (using an antenna noise bridge would work) we would be able to measure a 50-Ohm impedance and the transmitter would be able to put all its power into this resistive load. Looking into port B of the matchbox, we would be able to measure a 100-Ohm resistance in parallel with a 50-Ohm inductor, just the impedance we need for maximum power transfer into the antenna transmission-line impedance.

This example describes what you are doing when you adjust your antenna matching unit. The transmission line on the transmitter side of the matchbox has no reflected power in it so the transmitter is happy. The transmission line on the other side of the matchbox continues to have the same vswr as it did before but the matching network makes maximum power transfer possible from the transmitter into the antenna transmission line. Notice it has not made maximum power transfer possible into the antenna itself. To get this condition there would have to be something done to match the transmission line to the 130-Ohm antenna. Here the same principles of matching hold as we have already discussed. Get the driving impedance to look like a resistor equal to the load and cancel any reactive components in the circuit.

Conclusion

The "perfect match" in rf circuits is desirable and possible. Although you will make contacts without it, you will put less stress on your equipment and put more signal into the air if you study these principles and use them. Hopefully, this article has given an understanding of what happens when you tune your equipment and what causes the change in vswr as you adjust your transmatch. ■

Antennas Should Be Heard, Not Seen

Ham radio meets interior decorating! KC3HW's 2m J-pole wins the prize for unobtrusiveness.

To anyone but a ham, an antenna is a blot on the landscape. Those not in the amateur fraternity fail to see the beautiful symmetry, the subtle technique, and the reliance upon natural laws to which our skywires conform. Perhaps if we were to pose as artists rather than amateurs and call our creations "wire sculptures," the neighbors would be more tolerant.

I ran into this no-antenna problem upon purchasing my first two-meter rig. In my case, this was a hand-held. I picked the hand-held because of its greater utility. A hand-held can double as a mobile or base rig, but mobile and base rigs don't make very good hand-helds. Unfortunately, the decision brought an unforeseen problem.

At home, the hand-held and rubber ducky combination had only enough output to access the two local repeaters. On simplex, it was good for three miles (in Pennsylvania we have these natural rf absorbers called hills). It didn't seem right to me to spend all that money for eight hundred channels and then confine myself to only two.

I tried a 5/8-wave whip, but that was awkward. It made the hand-held top-heavy and frequently hit the walls and ceiling.

An outside antenna was out of the question. Our house wore a "For Sale" sign, and my wife already had trimmed the antenna farm down to one obscure forty-meter dipole. She absolutely refused to hear about another antenna on the house.

This unhappy set of circumstances forced me to begin scanning the literature on indoor two-meter antennas. In doing so, I discovered something that most hams living in apartments and condominiums must already know. It's this. Few two-meter-antenna designs are intended for permanent indoor installation. Those that can be adapted are too ungainly for the average wife to accept as a long-term addition to the decor. Hasn't anyone developed a permanent indoor antenna for two that's aesthetically acceptable?

Not finding a ready-made answer, I developed the Hidden Hypo described below. If you're an apartment dweller looking for an antenna with substantial gain over a rubber ducky, then

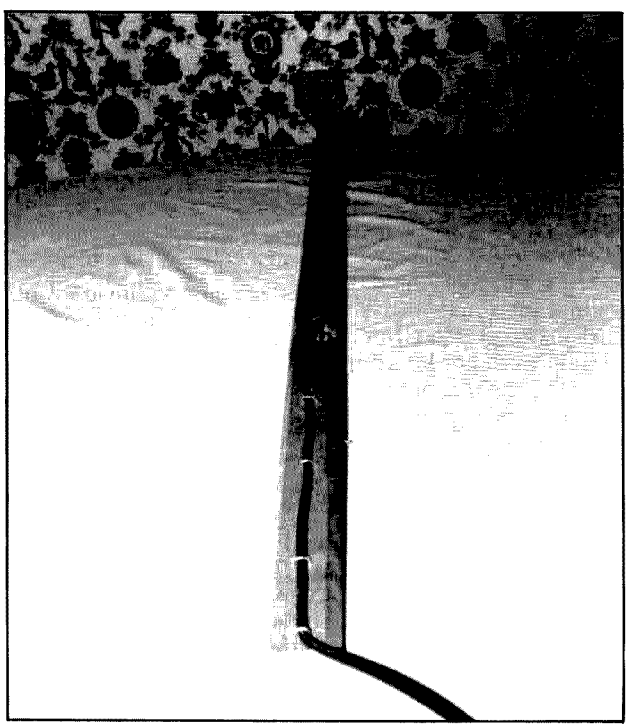

Photo A. The assembled Hidden Hypo (laid out on a bed) is mounted on the back of a piece of cove molding. Note that the coax is fastened to the back of the trim.

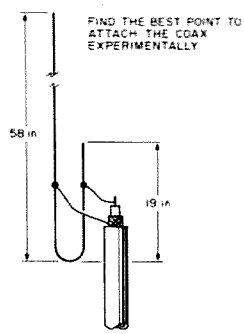

Fig. 1. The Hidden Hypo is really the well-known J-pole design. The spacing is not critical, but do keep the two legs parallel.

scure the bottom portion of the trim. Even if the corner is bare, the opening is still not noticeable since it's located well below the normal line of sight.

A variation of this approach can be used if you wish to mount the Hidden Hypo on a flat wall. Here, you'll have to use one piece of panel trim. (This trim may go under a number of names—check Fig. 3 for its profile; it's technically called WP-982) and two pieces of parting stop. Both pieces or their equivalent should be available at your local home-center store.

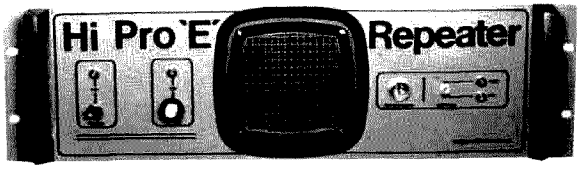
Mount the trim pieces as shown in Fig. 3. Drive finishing nails in just far enough to hold the pieces together. Mount the Hidden Hypo behind the assembly just as behind the cove mould. Place the entire assembly on the wall and continue to drive the finish nails through the trim and into the wall.

Once the antenna is installed, the cove mould or alternative trim can be painted to match or complement the wall.

One last thought. What do you do if and when you decide to remove the Hidden Hypo?

No problem. Make another trip to your local home-center store and pick up a small can of vinyl spackling compound. It will fill any holes that you may have left. Follow the instructions on the can.

Conclusion



The Hidden Hypo is an easily-constructed antenna for two meters. It's vertically polarized and omnidirectional. Perhaps the nicest part is that it provides a reasonable alternative for those like me who can't put up an outside antenna. It's not a twelve-element beam at fifty feet, but it sure beats the whips and rubber duckies! ■

Hi Pro 'E'

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.

• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.

• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

you'll find this interesting. If you're among those blessed with a good antenna, then the Hidden Hypo makes an excellent secondary antenna. Put it in the family room and monitor two meters while you sit and watch the game!

Design Considerations

King Solomon once said, "There's nothing new under the sun," and that's true for the Hidden Hypo as well. The basic configuration is the popular J-pole. However, while the design is well known, this antenna adds a couple of new wrinkles to it.

The first wrinkle is drastically reduced element spacing. Orthodox J-pole designs call for elements spaced three or more inches apart. The Hidden Hypo reduces this to one half inch.

At first thought, it may seem that bringing the elements this close together might create some undesirable interaction, but it doesn't. I experimented with spacings down to almost zero with good results. One half inch was chosen as a compromise. It was small enough to do the job yet wide enough to make construction easy.

The second wrinkle involves the method used to mount the antenna. The thin needle-like design (hence the name, Hypo) allows it to be hidden in places previously not possible.

Now, if this antenna were mounted on the back side of a piece of cove molding, the entire unit would fit in the corner of a room. Except for the coax leading to it, there would be no way of telling that an antenna was there.

For those not familiar with the construction industry, cove molding is most commonly used to trim a room where 12" × 12" ceiling tile has been installed. The trim (for our purposes) has three important features. First, it's nearly symmetrical, allowing it to be used as inside corner trim. Second, when installed, there's an open space behind it large enough to accommodate the antenna. Third, it's a commonly available material. The cove molding, along with the rest of the material used to construct this antenna, is available at most home-center stores and lumber yards.

Construction

The principal material used to construct the antenna is a seven-foot piece of 14-gauge insulated wire. I obtained mine by cutting it out of a piece of Romex electrical cable.

Pull the wire taut so that it's straight and then cut it to 77 inches. Measure up 19 inches and fold the wire back over on itself. You should end up with a U-shaped wire with one leg 19 inches and the other 58 inches.

From the fold, measure up 3-1/2 inches on each leg. Strip the insulation off each leg from this point to 7 inches above the fold. The antenna configuration is now complete and ready to be mounted onto the back side of the cove molding.

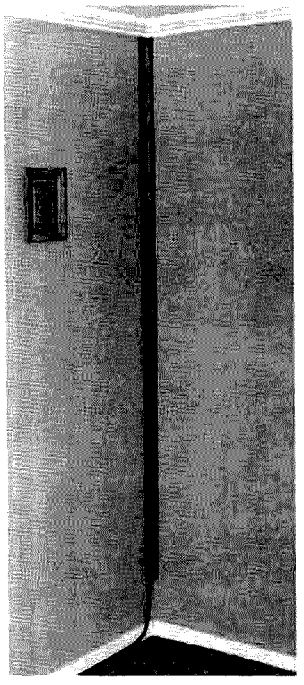

Photo B. Now you see it... The Hidden Hypo is mounted on the back of this piece of unpainted trim.

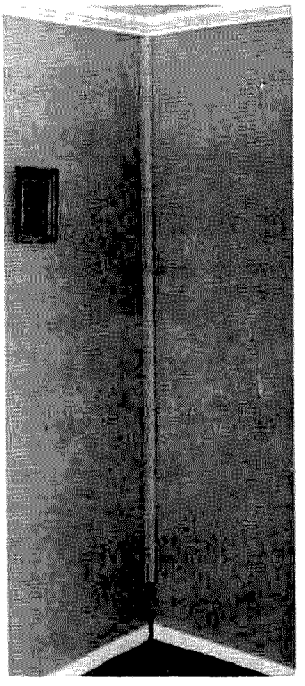

Photo C. Now you don't. The painted trim blends in with the rest of the room.

Lay the 58-inch leg on the cove molding and fasten the upper portion only. The section stripped of insulation and the 19-inch leg must remain free.

I used an Arrow T-50 staple gun and 9/16-inch staples to fasten the antenna. If you don't have access to a similar gun, you may choose to fasten the antenna using electrical wire brads.

Before completing the fastening process, carefully align the 19-inch leg so that it's parallel to the longer leg and spaced no more than 1/2 inch from it. If you get things too wide, the antenna will interfere when mounting the trim in the corner. It is *most* important to keep the spacing uniform. Don't let the elements assume a vee shape or belly apart. Nonuniform spacing will cause wild fluctuations of the swr meter when matching the coax to the antenna.

Next, expose the braid and inner conductor of the coax. Wrap but don't solder the braid to one leg and the inner conductor to the other leg. Apply power to the antenna and slide the coax up and down the uninsulated section of the antenna. At some point, the swr meter will dip. Solder the coax to the antenna at that point.

If you don't have a VHF swr meter available, you can solder the coax 5 inches above the fold. That will be close, but I recommend the meter method.

Finish fastening the antenna to the cove molding, being careful to preserve the alignment of the antenna elements. Use the 9/16-inch staples to fasten the coax to the cove molding, also.

Next, trim the molding so that it is an inch or two shorter than the length of the corner that it will fit in. Use this gap at the bottom to draw the feedline out from behind the molding.

At first, this might not seem aesthetically acceptable, but the situation isn't bad. In most cases there's something there to hide the opening. Corners naturally attract chairs, tables, and lamps which tend to ob-

A Connoisseur's Microwave Converter

Brent Harry set out to build not the cheapest but the best downconverter possible. Serious microwave buffs will thank him.

This article describes the design and construction of a new microwave converter for use with either the 6-MHz MDS or the amateur-television allocation, centered at 2.153 and 2.314 GHz respectively. With the broad tuning range of its local oscillator, this converter could be used elsewhere, although the design was optimized for 2.153 GHz.

Since there are so many pre-built units, kits, and plans already available, why another? This converter's performance is very respectable, and its design offers other advantages such as high reliability and simple construction for those who prefer to build their own; however, I obtain these results at the cost of high-quality components. For example, both the high-gain input amplifier and high-stability reflection oscillator use high-performance H-P HXTR-2102 microwave transistors, $31.00 each, wholesale. Fortunately, the other components are much less expensive.

I conceded the necessity of expensive microwave transistors only after building many subsections and complete models with inexpensive ones. I also built models with more expensive low-noise gallium arsenide MOSFET input amplifiers (which are nearly mandatory at the 22,000-mile geosynchronous satellite distance), but biasing is more difficult and they did not provide a noticeable improvement in reception quality at the relatively trivial distances involved here, so I chose the lower-cost bipolar devices.

All microwave circuitry was designed with the modern scattering-parameter approach, facilitated with an H-P S-parameter test set, 8566A spectrum analyzer, microwave frequency counter, test ovens, etc.

Some of the features are: easy construction and stan-

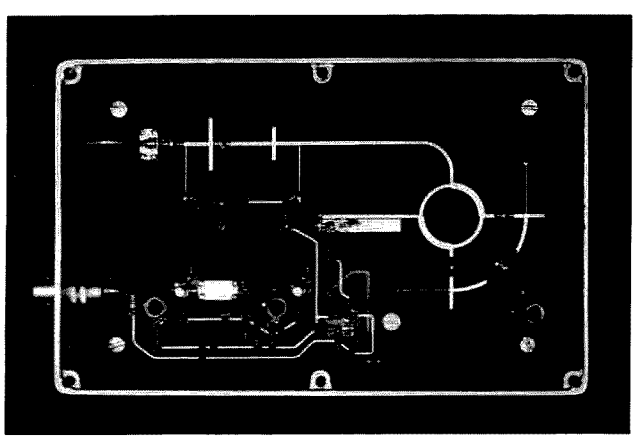

Photo A. This is what the circuit board looks like after being inserted.

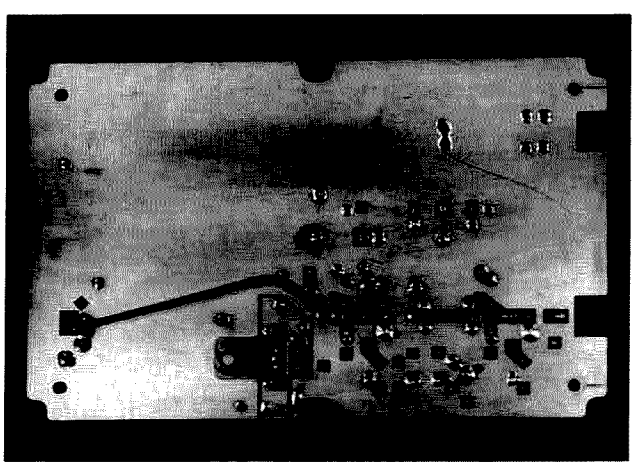

Photo B. The ground-plane side of the circuit board.

dardized performance with a double-sided etched board requiring no hand wiring, an input amplifier, a high-stability local oscillator, impedance matching for all microwave circuitry, an on-board regulator so that the variable tuning voltage affects only the local oscillator, and appropriate microwave-input connectors. All critical microwave tuning is predetermined by etched microstrip transmission-line segments.

The circuit board stands on ¼-inch spacers in a die-cast-aluminum case with a tight flange lid; the case is easily sealed with silicone rubber at the lid and the bases of the spacers if the correct rubber-gasketed connectors are used.

I taped a just-baked desiccant capsule (humidity absorbent) inside the cover immediately before sealing the case to prevent water or ice formation at cold temperatures. I used the indicating type which changes from blue to pink when it has absorbed its limit of water vapor. The photographed units were finished with almond-color epoxy spray paint. A light anodized finish would be more durable, although bare aluminum would be fine.

Of course, I don't claim originality for several aspects of this system, such as the use of the single downlead to supply dc power to the converter, dual-gate MOSFETs in the output amplifier, a parabolic dish antenna with a can feedhorn, or a commonly used hybrid junction (or "rat-race") mixer. I chose the circular form of this ring over the more common square form because the boundaries are more clearly defined. My earlier designs used a different ring with a differential output, driving a differential-input wideband IC amplifier; I finally accepted the present form as superior.

What about performance? Let me first say that I am wary of advertised high performance at low cost, especially when I see formed plastic. Since gain is an effective eye-catcher, insertion gain of the converter itself tends to be forsaken for system gain of the converter/antenna combination, especially when a reasonable-size parabolic dish can provide over 30-dB gain (measured with respect to a dipole). Of course, there is more to consider than gain, as noted ahead in the input amplifier section. Oscillator stability is one other measure of performance which is rarely advertised, and which I refuse to compromise.

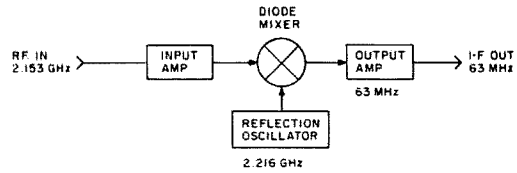

Fig. 1. System block diagram.

With a −70-dBm input at 2.153 GHz, the converter insertion gain is 38.0 dB with its output tuned to channel 3, centered at 63 MHz. An adjacent channel could be used instead. One could expect higher gain in actual use, driving a 75-Ohm television input instead of a 50-Ohm spectrum analyzer. Note that −70 dBm represents only 0.0001 microwatts since the 0-dBm reference is 1 mW into 50 Ohms; with 38.0-dB gain, the output would be 0.631 microwatts. I chose −70 dBm since it was slightly above the spectrum analyzer's threshold.

At 2.216 GHz, the off-to-on oscillator drift at room temperature is 0.3 MHz, indicating a stability of better than 0.014%, and drift over the temperature range −30° C to 60° C (−22° F to 140° F) is under 1.3 MHz, indicating a stability of

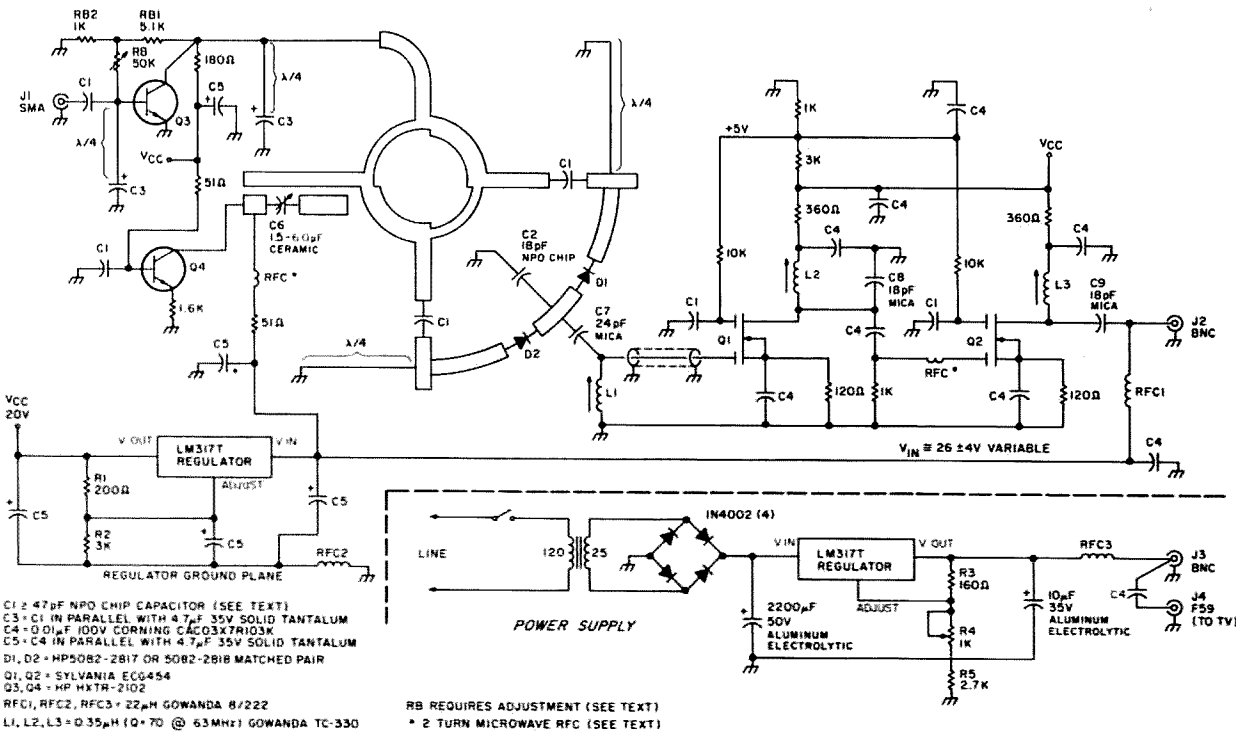

Fig. 2. Complete converter schematic.

better than 0.06%! I chose this temperature range since it should include any temperature seen in actual use.

Note: To achieve my measured gain and stability, it is essential to use high-quality (expensive) NPO chip capacitors which are qualified at 2 GHz. I've measured much higher drifts and lower gains while experimenting with other chip capacitors. The most important chip capacitors are at the base of the local oscillator and at the mixer, so at least those should be high quality. Expect to pay $5.00 to $10.00 apiece for appropriate capacitors.

I developed this project while living in Redondo Beach, California. This was a flat, indirect-signal location 32 miles from the transmitter in the LA area. I would have needed a tower for line-of-sight reception, so I used a 24-inch parabolic dish mounted on a camera tripod at ground level on the lawn. I could receive a fair (snowy but watchable) image in several directions because of reflections, but I had to aim at either the telephone lines or a large tree down the street in order to receive a good picture (one with easily-readable fine print). At this poor signal location, I could receive a fair picture even without the dish, or sometimes (depending on atmospheric conditions) a very poor one from inside the house, through the wall.

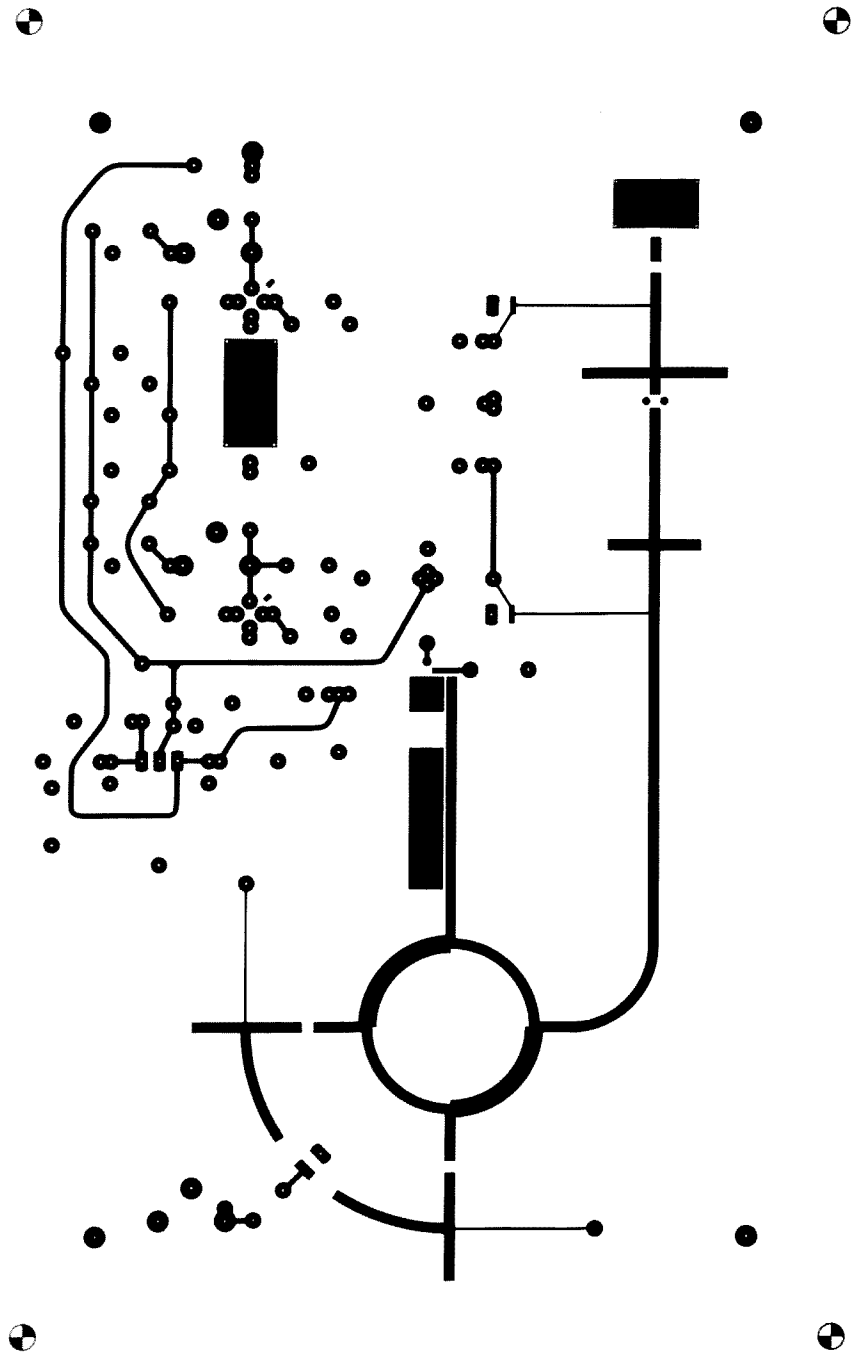

Fig. 3. Circuit board, component side.

Aren't microwave signals strictly line-of-sight and severely attenuated by obstacles? Yes, and that is an indication of this converter's sensitivity. I've tested this setup at other locations: It produced an excellent picture at a good line-of-sight location 21 miles from the transmitter, and a fair one at a partially tree-blocked location 65 miles from the transmitter. Doubling a given parabolic dish's diameter will quadruple the received signal power.

The block diagram and schematic diagram of the system are shown in Figs. 1 and 2, respectively. Photos A and B are views of both sides of the completed circuit board to aid in parts placement. Figs. 3 and 4 are illustrations of the front and rear sides of the etched board.

I did the artwork on a 4× scale for the sake of precision. For those who prefer to etch their own, let me stress that as well as accurate alignment, the correct circuit board material and thickness are essential since both affect the various microstrip transmission-line impedances. The material is NEMA type-FR-4 flame-resistant glass-epoxy, with a relative permittivity (dielectric constant) of 4.5 at 1 MHz. The required thickness is 0.031 inches. The board should be electroless-plated with gold or silver after etching, since bare copper deteriorates.

As well as supporting the circuit board, the aluminum spacers in each corner also electrically connect the ground plane to the aluminum case. Therefore, the spacers are mounted to the case with screws and no protective spray or other insulator should be used; do not glue-mount the spacers.

To locate the holes, I taped two-sided adhesive tape in the bottom of the case, placed the circuit board with screwed-on spacers into the case so that the spacers stuck to the tape, then unscrewed the screws from the spacers. When the circuit board was lifted out, the spacers were still stuck to the tape in their necessary positions. I had only to outline each spacer with a pencil before removing it. If the box has been totally anodized, be sure to sand the areas where the spacers and connectors make contact with the case.

Since the dimensions of the aluminum case are large with respect to the input wavelength but very small with respect to the output wavelength, the output BNC connector can use the case for its ground connection, although the input SMA connector cannot. That is why there is a ground pad for the input microwave connection. Short pieces of bare 26-AWG wire are used to connect each corner of both square ground pads to the ground plane, as well as the ground side of the 18-pF mixer-diode chip capacitor, and the ends of the four thin quarter-wave bias stubs. The two mixer stubs are terminated with a dc ground, but the two input amplifier stubs are terminated with a chip capacitor to ground.

As shown in Photo B, the only components on the ground-plane side of the circuit board are: chip capacitors to ground at the base of the local oscillator and gate 2 of both MOSFETs; the voltage regulator, insulated from the ground plane with a mica washer and nylon screw; a short piece of 50-Ohm semi-rigid coaxial tubing used to connect the output of the mixer resonator to gate 1 of the first MOSFET; and a noncritical 2-turn microwave choke, wrapped on a 5/32-inch drill bit at the input of the second MOSFET to prevent it from becoming a microwave oscillator.

The two emitter leads of the local oscillator transistor are trimmed down to about 2 mm long before the base lead is gently bent to go through the board at a right angle. The two pads for the oscillator's emitter and base resistors are intentionally undrilled so that the ground plane is continuous in the vicinity of the oscillator's base lead, which is grounded with a chip capacitor on the ground-plane side. The input amplifier's two emitter leads are similarly bent to go through the board, but are soldered directly to the ground plane.

Another noncritical 2-turn microwave choke, wrapped on a 5/32-inch drill bit, is formed as an integral part of the oscillator's collector resistor. Be careful to correctly identify the collector terminal of each microwave transistor (cut at an angle). The separate regulator ground

plane and solid tantalum capacitors are necessary because of the noise-generating regulator. Other types will not provide proper bypassing. The two ground planes are connected with a molded choke. Once the circuit board has been completed and screwed down on the spacers, the input and output connectors are soldered, and the converter is ready for tune-up.

Power Supply

The power-supply circuit of Fig. 2 is simple and noncritical, so I haven't illustrated the physical construction. Mine is built in an inexpensive cabinet with rubber feet, using terminal-strip hand wiring. The two connectors should be adjacent to each other with a good shared case ground. The supply provides approximately 26 V ±4 V to the converter, producing ample tuning range. One possible modification would be the addition of an antenna switch.

Mixer

The mixer has two inputs: the amplified input signal and the local-oscillator signal. The hybrid junction ring which couples these two inputs to the mixer diodes has four functions: (1) It isolates the signals from each other, (2) it provides a 50-Ohm load for each signal, (3) it allows each signal to divide equally in power between the two output arms (each diode receives two signals with respect to ground; the common connection of the two diodes looks like ground at microwave frequencies), and (4) it provides the proper positional phase relationships for these microwave input signals so that the mixer diode outputs reinforce each other.

A Smith Chart rotation and stub tuner transforms each diode's impedance to 50 Ohms so that the ring will operate properly and maximum power transfer will occur. This is why the mixer diodes are not connected directly to the output arms of the ring, as could be done if the diodes themselves were 50 Ohms. Unmatched designs do this, hoping to achieve 50 Ohms by driving 1 mA or more of noise-producing dc bias through the diodes. The correct method is to measure diode impedance at a particular absorbed (not incident) power, construct an appropriate matching network to transform that impedance to 50 Ohms, then adjust the local oscillator to provide the required absorbed power.

One very convenient method of monitoring absorbed power is to measure the "self-bias," which is the average rectified current driven by the local oscillator. To maximize mixer conversion efficiency, I chose 3-mA self-bias. My earlier models did use a small amount of dc bias, but this did not improve conversion efficiency whatsoever (which is not

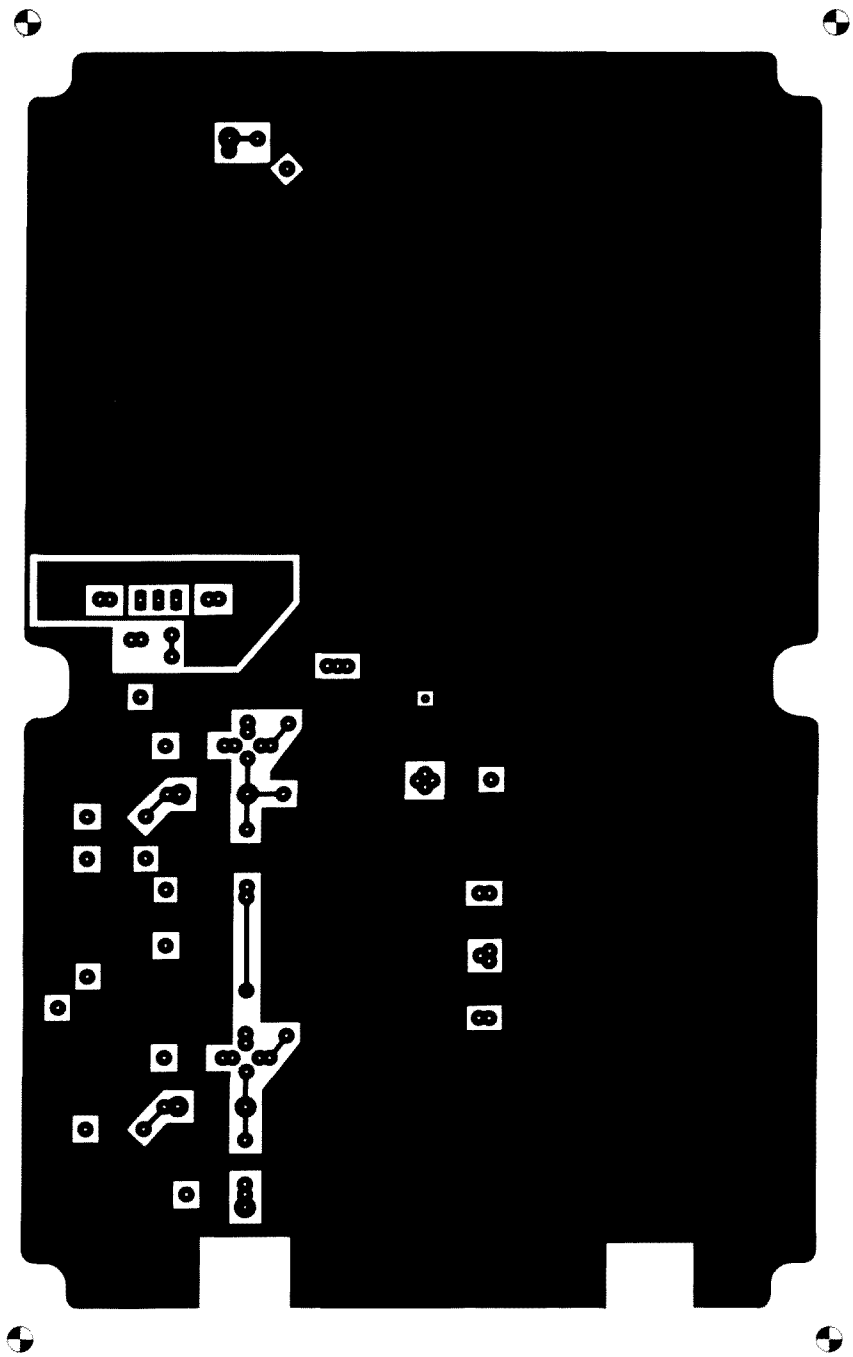

Fig. 5. Circuit board, ground-plane side.

true of all mixers). This mixer uses H-P 5082-2817 Schottky diodes, intended for low-noise, high-sensitivity mixing at 2 GHz. Using other mixer diodes would of course ruin the matching. If desired, the self-bias can be measured by cutting one of the bias stubs near its dc ground end, inserting a chip capacitor, and connecting a milliammeter across it (yes, current is made to flow from dc ground through two diodes, back to dc ground). The chip capacitor must be replaced with a short when finished to complete the dc return path. The diodes must be connected in series (either direction) for a dc path to exist.

Local Oscillator

The tuning range of this oscillator is approximately 1.8 to 2.4 GHz with the power supply set at mid-range. Because of the unusually large emitter resistor and emitter-resistor voltage (large dc negative feedback), the dc operating point of this transistor is held very constant over wide variation of the temperature-sensitive dc beta and V_{be}. This and the mode of oscillation produces the high stability already mentioned.

As stated earlier, this is a reflection oscillator. The frequency of oscillation is not determined by a feedback network; there is no feedback. The base is grounded with a chip capacitor and the collector serves as both the input and output. Looking into the collector, there is a range of frequencies over which the reflection coefficient is greater than one, indicating negative resistance. When attached to a resonant circuit with the correct reflection coefficient (in this case, a series-tuned microstrip segment), the transistor oscillates. The oscillator is capable of a much higher power output, but its bias network should not be modified since its power output affects the mixer-diode impedance for which the matching network was designed.

Input Amplifier

High output amplification will do nothing to better a system with a poor noise figure; however, high input amplification can cut a system noise figure in half while doubling system gain. System gain is the sum of stage gains in dB, but a system noise figure is more involved:

$F_{system} = F_1 + (F_2 - 1)/G_1 + (F_3 - 1)/G_1G_2 + (F_4 - 1)/G_1G_2G_3 + \ldots$

where F and G are stage noise figures and gains (power ratios, not dB).

An input amplifier is beneficial in terms of noise figures as well as in terms of sensitivity, gain, and oscillator-antenna isolation. There are many different criteria to choose among in microwave-amplifier design. This one uses narrow-band matching to achieve maximum power transfer into the 50-Ohm load while providing a 50-Ohm-input impedance. One alternative approach, designing the input amplifier for minimum noise figure instead, would have reduced the gain, possibly increased the system noise figure, and required precise antenna matching.

The input amplifier's S-parameters which were used to design its matching stubs are sensitive to changes in the dc bias. In

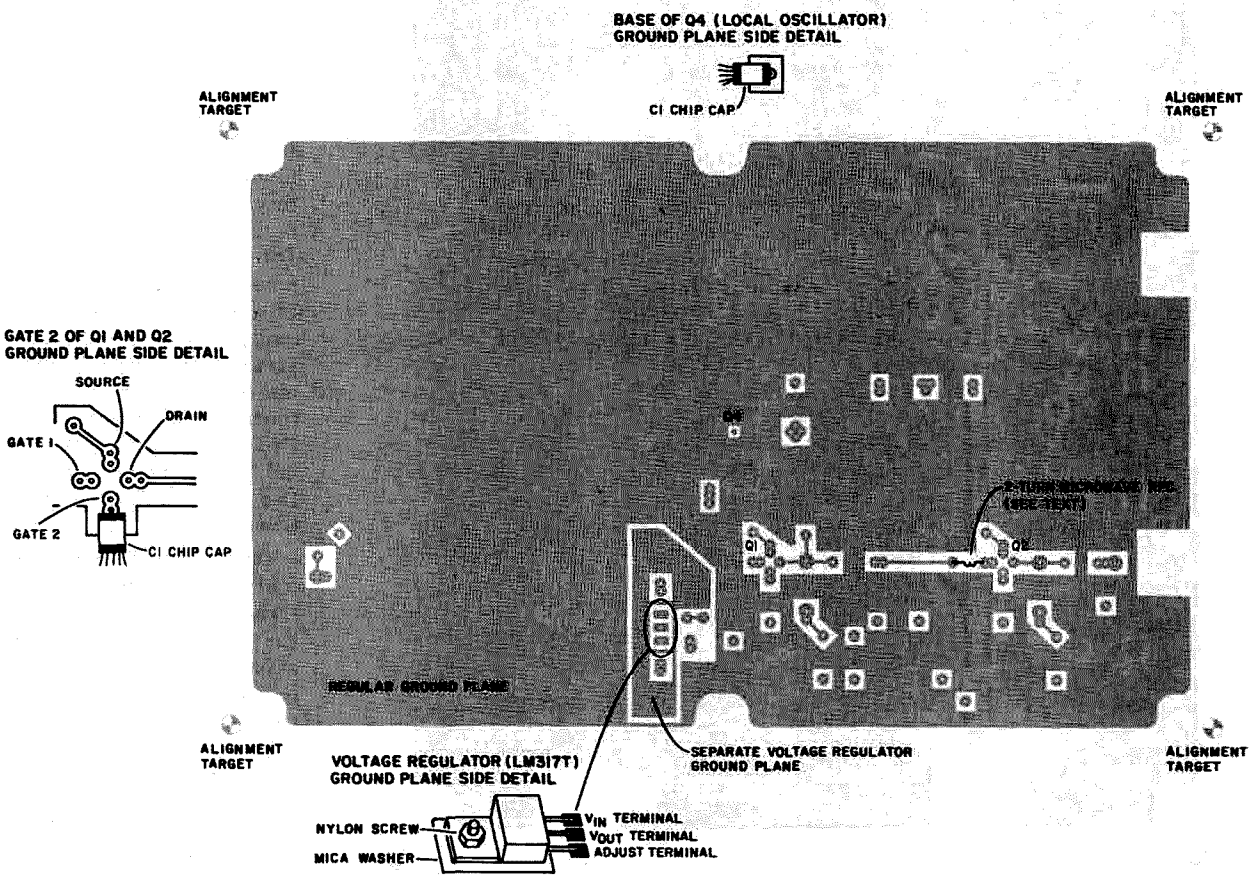

Fig. 6. Parts placement, ground-plane side.

Parts List

- 2 Microwave transistors: Hewlett-Packard HXTR-2102
- 2 Schottky mixer diodes: Hewlett-Packard 5082-2817
- 2 Dual-gate MOSFETs: Sylvania ECG-454 or similar
- 2 LM317T voltage regulators
- 3 .28- to .42-uH slug-tuned inductors (Q = 70 @ .35 uH & 63 MHz): Gowanda Electronics TC-330 or similar
- 3 22-uH molded chokes: Gowanda Electronics 8/222 or similar
- 2 Gold-plated female SMA connectors with rubber gasket, for 0.085" semi-rigid tubing: Amphenol 901-9210-2
- 2 Gold-plated male SMA connectors for RG-316/U coax cable: Omni-Spectra OSM 601-3
- 1 Female BNC bulkhead connector with rubber gasket: Amphenol 31-102 or similar
- 1 Female BNC bulkhead connector: Amphenol 31-221 or similar
- 2 Male BNC connectors for RG-59/U coax cable: Radio Shack 278-104 or similar
- 2 F-59 connectors for RG-59/U coax cable: Radio Shack 278-211 or similar
- 1 F-61 connector: Radio Shack 278-212 or similar
- 6" 0.085"-diameter, 50-Ohm semi-rigid coaxial tubing (copper-jacket tubing)
- 3' RG-316/U 50-Ohm coax cable
  RG-59/U 75-Ohm coax cable for downlead and connection to TV (under 3-dB loss per 100 feet at 63 MHz)
- 8 47-pF (or larger) NPO ceramic or porcelain chip caps (not critical; 18 pF will work) such as Union Carbide
- 1 18-pF NPO ceramic or porcelain chip cap such as Union Carbide
- 1 18-pF mica cap: Cornell-Dubilier CD10-CD180J03 or similar
- 1 24-pF mica cap: Cornell-Dubilier CD10-ED240J03 or similar
- 1 1.5-to-6.0-pF microminiature ceramic trimmer such as Erie* (range not critical; e.g., 2.0 to 10 pF would work)
- 14 0.01-uF miniature ceramic caps: Corning CACO3X7R103K or similar
- 7 4.7-uF, 35-V aluminum electrolytic cap
- 1 10-uF, 35-V aluminum electrolytic cap
- 1 2200-uF, 50-V aluminum electrolytic cap: Digi-Key 2200/50A or similar
- 1 1k linear potentiometer

¼-Watt, 5% carbon composition resistors (film should work)

- 2 51-Ohm
- 2 120-Ohm
- 1 160-Ohm
- 1 180-Ohm
- 1 200-Ohm
- 2 360-Ohm
- 3 1k-Ohm
- 1 1.6k-Ohm
- 2 2.7k-Ohm
- 2 3k-Ohm
- 2 10k-Ohm
- 1 5.1k-Ohm
- 4 1N4002 or similar rectifier diodes or molded bridge
- 1 25-V power transformer: Radio Shack 273-1512 or similar (the converter draws 57 mA: a light-duty transformer could be used instead)
- 1 Power-supply cabinet: Radio Shack 270-252 or similar
- 1 7" x 5" x 2" diecast-aluminum case with flange lid: Bud CU-247

*Typical potentiometer: Bourns, part #3262W, hermetically-sealed microminiature potentiometer, 12-turn, 50k. This is a high-quality trimmer availble only from industrial suppliers. The unit cost is $9.22, but a similar inexpensive pot can be substituted. Substitutes should also be hermetically sealed, however.

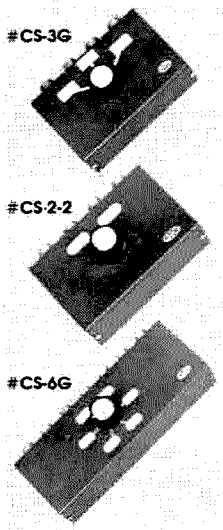
effect, changing the bias changes the tuning. That's one reason why an on-board regulator is necessary. Unfortunately, an emitter resistor can't correctly be used with the input amplifier as was done with the local oscillator, so a different negative-feedback network which requires an initial adjustment was necessary.

Optimum performance won't be achieved if the bias conditions differ very much from the required V_{ce}=15 V and I_c=25 mA. To compensate for differences in dc beta between similar devices, the input amplifier's base resistor, R_B, should be chosen to provide this bias point accurately. Note: For both the input amplifier and local oscillator, be very careful to apply V_{cc}=20 V only after the bias network is complete because the open-base breakdown voltage, V_{ceo}, is 20 V; the transistor may be destroyed otherwise. With the base connected, BV_{ces}=30 V, minimum, so there is no danger if the network is complete.

Accurately measure all the input amplifier's bias resistors before they are soldered in so that I_c can be calculated from their operating voltage drops. Adjust base potentiometer R_B to approximately 10k after connecting its wiper to either end, and then solder its two ends into the board. Note that the photographed board used a fixed resistor for R_B; finding an accurate fixed value is a tedious process. During tune-up, power is applied (via the BNC connector) and R_B is adjusted to provided V_{ce}=15.0 V. I_c is then calculated from the bias network voltages and resistances.

It probably won't be possible to simultaneously achieve the required current and voltage exactly without varying R_{B1} as well as R_B, so a tradeoff is necessary; e.g., 15.2 V and 25.2 mA would be a better choice than 15.0 V and 25.6 mA. The input and output of the input amplifier are shunted to ground through quarter-wave bias stubs with a chip and tantalum capacitor. This acts as a shunt bandpass filter, shorting all lower frequencies.

Output Amplifier



This is a basic two-stage amplifier with three resonators to provide the desired overall bandpass response. Although MOSFETs have advantages over bipolar transistors, one precaution which must be observed has to do with susceptibility to static discharge. It would be a good idea to connect the MOSFETs last, working above a grounded benchtop. Once soldered in, the danger is over.

Tune-Up

After the converter has been built but before connecting any of the four transistors, the first step is to measure the output of the on-board regulator with an input of about 25 V; if it doesn't supply an accurate 20 V, adjust one or both of its resistors Until it does:

$$V_{cc} = 1.25[1 + (R_2/R_1)].$$

Next, after the board is completed (with R_B preset) and mounted in the case with the connectors soldered, tune-up consists of adjusting R_B as already explained, adjusting the local-oscillator frequency with its trimmer capacitor (with the power supply set at midrange), and then peaking the three slug-tuned output-amplifier inductors, which provides a 6-MHz overall bandpass response. In actual use, with the output resonator loaded by a 75-Ohm television input instead of a 50-Ohm spectrum analyzer, the response would be broader.

The local-oscillator signal can be monitored at the converter output with either a spectrum analyzer or microwave frequency counter if either is available. If not, the transmitted signal should be usable for tune-up since the resonators don't peak sharply. Butterworth bandpass response would require different component values, and alignment equipment would be mandatory. For an input at 2.153 GHz and the output tuned to channel 3, centered at 63 MHz, the oscillator is tuned to 2.216 GHz. The voltage tuning range is broad enough to tune both the correct and image oscillator frequencies.

My antenna consists of a feedhorn placed at the focus of a parabolic dish. In a strong signal location, a dish isn't necessary; the feedhorn itself can be used as the antenna since the dish only increases the area over which the signal is collected. The feedhorn produces a microwave standing wave within itself so that the signal can be picked off with a quarter-wave dipole. For a given frequency, the dipole's optimum position in the feedhorn depends on the "guide wavelength," which depends on the radius of the circular waveguide used. I prefer to use other than coffee cans because of their ribs. I chose a can which was used to ship silicon wafers because the sides and end are very straight and smooth, more like a commercial waveguide section. This means cleaner internal reflections with no scattering.

For a feedhorn with a 2.0-inch radius operating at 2.153 GHz, the dipole is placed 5.8 cm from the closed end of the can (parallel to it). The dipole should be oriented vertically since that is the normal transmission polarization. There may be an adjacent channel with horizontal polarization. The quarter-wave dipole is made by soldering a piece of semi-rigid coaxial tubing to an appropriate SMA connector, removing the shield all the way to the connector, and then trimming the center conductor to 3.3 cm long. I use thin silver/teflon RG-316/U cable with an SMA connector on each end to connect the antenna to the converter. The input impedance was designed to be 50 Ohms; it should be possible to use other antenna systems, cable configurations, or preamplification stages if desired.

Summary

When I completed the project, I was entirely satisfied with this converter and felt I could recommend it to others without reservation. Unfortunately, I have since experienced one problem with the most recent set of ten HXTR-2102 transistors I purchased: Some input amplifier transistors have failed, even though they were operated at the manufacturer's recommended bias point. There have been no local oscillator failures, but these are operated at a lower power level. This seems to be a manufacturer's isolated lot problem, but I can't be certain since I no longer have access to the array of sophisticated equipment used during development. This problem may be augmented by the tantalum capacitor on the base of the input amplifier transistor, since this holds the transistor off for approximately 10 milliseconds; with no current being drawn, 20 V appears at the collector for this time. Although it doesn't strictly apply, this happens to equal the absolute maximum rating for V_{ceo}. As a precaution, one may want to remove this tantalum capacitor and run the on-board regulator at 19.1 V instead of 20.0 V by changing R1 from a 200-Ohm to a 210-Ohm, 1%-tolerance resistor. If no other changes are made, the input amplifier will then be slightly detuned by operating somewhere near 15 V and 20 mA, depending on the adjustment of R_B. One can always totally eliminate the input amplifier transistor by removing all the bias and tuning stubs from the input line with a razor blade and using a copper-foil short in place of the transistor; this would mean the loss of about 14 dB of gain and some sensitivity.

For a better understanding of this project's design, or for practical application in another project, copies of my design notes are available. They include explanations, test data, and all calculations, including Smith Charts, waveguide and microstrip calculations, and a table of microstrip transmission line impedances. I will send copies of these notes first-class postage-paid for $4.00. Many parts are available only from industrial suppliers and so are difficult to obtain. I intend to supply a set of parts; write to me for details. ■

Get With the Program and Speed Up Your Code

Here's an opportunity to increase your code speed without QRM, QRN, or QSB!

As the son of two licensed amateur-radio operators, it was natural that I would find hamming an interesting hobby. The theory was no problem for me as I have always been interested in electronics, but the code did not come quite so easily. I practiced and practiced, and finally passed my Novice examination.

Soon after receiving my Novice license, I realized that upgrading was a must. The code requirement of thirteen words a minute seemed insurmountable. Because I am a high-school student, my time is somewhat limited and time devoted to code practice became less and less. Finally I decided to wait for the summer, when I could devote as much time as I wanted toward getting my General ticket.

The summer came, but I soon realized that I was not making any progress trying to increase my code speed by operating in the Novice bands, and as an Apple computer enthusiast, I decided to put my computer to work with a program to send random code.

After I completed this program, I modified it to show me what it sent and to check my copy for any errors. Back to the drawing board once again. The new program would send the code and then prompt for the letters, numbers, or symbols when it was finished sending whatever number of characters the user desired. I also added into the program a method of scoring the user for the number of correct and incorrect characters copied. The next problem that I faced was: If I missed a number of characters while I was practicing, I could not be sure which character was next in line when I was checking what I had copied. I overcame this by having the program show the user all of the characters on screen in the order sent.

When this program was completed I still wasn't satisfied. It was partly because I enjoyed working on it and I was sorry the effort was over; so I rewrote the program with several enhancements. First I made it menu driven. The user can select the mode of practice he wants to take, the speed, and the tone, all from a series of menus.

Other enhancements included a drill that shows on the screen the character sent less than a second after the code sound is sent. This gives the user enough time to recognize the character in his mind, but not enough time to think about it or break down the character in his mind.

The new version of the program was just about complete when I decided there was one more modification it needed. I made the program keep the speed that the character is sent at 15 wpm and varied only the time between characters. The menu allows you to select the code speed you wish to copy, but only the space between characters changes, not the speed of the code itself. This results in a program that makes it easier for you to increase your speed because you are already used to the pattern of faster code. This method also makes taking the code apart in your mind almost impossible; you learn to recognize the characters only by their sound.

This program is written completely in Applesoft Basic and will work on the Apple II+ or IIe. It uses two machine-language subroutines that are POKEd into memory when the program is run. These routines are at location $300 and perform two needed functions that can be used in your own programs.

The first of these routines generates the tones. If you run this program and then exit it, the routines will be in memory. You can BSAVE them for your own use. To use the tone routine, POKE the pitch into location $0 and the duration of the note into location $1; then CALL 768 will play the desired note.

The second of these routines is used to scramble the random-number generator. This is done by scanning the keyboard and choosing a random number. If a key is pressed, then it continues, and if not, it does it again and again. This means that while waiting for a keypress, the program is scrambling the random numbers that will be used. This is needed because when the disk is first BOOTed, the random-number generator is given a seed number. The routine just steps through these to make them "more random."

To begin, run the program. A menu will appear on the screen and ask for your choice. The choices displayed are, first, practice drill, which is a drill that is scored and will prompt for the number of characters

you desire to receive. The second option is the visual drill. This drill shows the character sent on the screen just after it was sent. The third option on the menu is to change the tone. Enter a number from one to 255. The fourth option is the speed control and gives a sub-menu with your choice of speeds. The last option on the menu is to exit the program to Basic. Any key pressed other than those indicated will be ignored. When you use the first drill, the speed remains unchanged. This is not the case with the second drill. The second drill, when exited, will reset the speed back to 15 wpm. When the program is run, all speeds are set to 15 wpm until changed.

This program, as well as your Apple itself, can be greatly enhanced by adding a simple and inexpensive modification. The Apple is a remarkable piece of hardware, but there is a flaw. The audio of the Apple is not up to par. Part of this is due to the small size of the speaker. With the following simple modification, you can give your Apple a very loud voice.

An audio output transformer is required, such as Radio Shack part number 273-1380. The primary of the transformer (blue and green leads) is connected via a length of shielded cable to the auxilary input of any amplifier. The secondary (red and white leads) is connected to the speaker of the Apple. The best way to do this is to splice into the wires of the speaker. The speaker of the Apple is located face down on the left side of the Apple near the keyboard.

When this modification is made, the center tap of the primary of the transformer (black lead) should be cut off; it is not needed. The audio of the Apple will work normally but also will be fed through your amplifier. I use the amplifier in my color monitor. This simple modification will make this code program more useful and will enhance any Apple application using sound.

This program has helped me and I hope that it will help you, too. The modification can be made with only a small investment in a transformer and some cable. This program will operate without it, but by enhancing the sound of the computer, the program sounds better. Due to the excessive length of this program, I will supply it on a DOS 3.3 disk upon receipt of a check for $10.00 and a self-addressed mailing label.

Here is your opportunity to increase your code speed with no QRM, QRN, or QSB, and at your own convenience. Enjoy!■

The Potabilities Are Endless

Dunk your next project into icky goo and discover why potting a circuit is even more fun than building it.

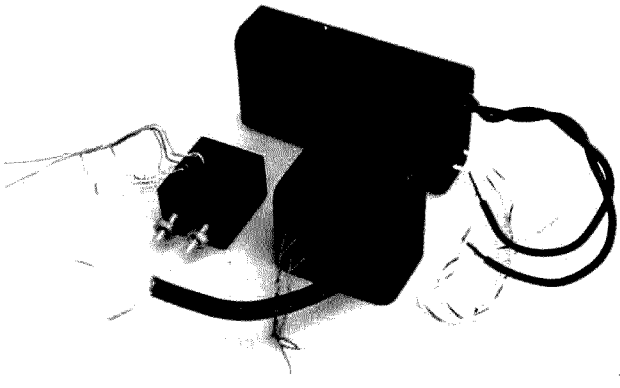

Photo A. Some examples of potting.

Have you ever had a circuit that you wished could be weather-proofed or ruggedized for severe vibration or other environmental effects?

Potting, or plastic encapsulation, could be the answer. Virtually any circuit can be encapsulated if it meets a few basic requirements. Number one, it should be completely tested to be sure it will operate satisfactorily—black cubes are hard to troubleshoot! Two, no adjustable components will be accessible once potted, so they cannot be included within the module. Connecting leads can be brought out, however, and variable components can be mounted externally. The third and last requirement is that the package should be relatively inexpensive. If something goes wrong, you're looking at a throwaway item unless you're into dissolving the potting compound.

The secret potting compound? It's available at any auto supply store; it's automotive body filler! Sold under many different brands, it's a polyester resin with styrene monomers added. A hardener is added to the mixture, and the substance

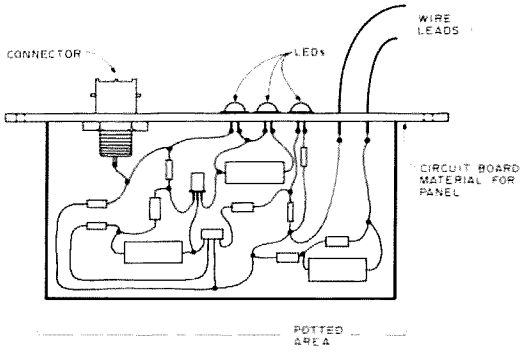

Fig. 1(a). A potted assembly which includes a panel for connectors and indicators.

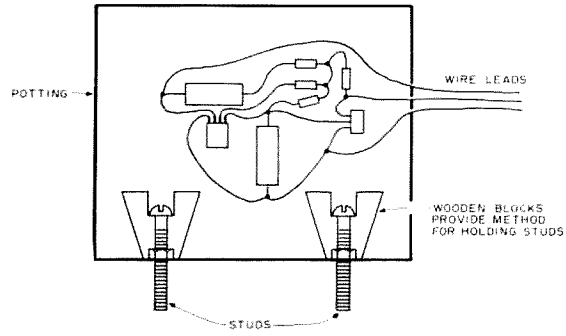

Fig. 1(b). A potted assembly with mounting studs which extend through the mold during curing.

cures in about 30 minutes. (Follow the directions on the container.) I have tested a number of different brands and all seem to have excellent mechanical properties and good dielectric strength. A 15-kV power supply potted over a year ago has functioned perfectly with no indication of insulation breakdown.

Making modules is easy; you can "hay-wire" the interior electronics together, saving on mechanical supports, sockets, and hardware. Make sure, however, that all solder connections are good and that nothing will short together during potting; don't forget to test!

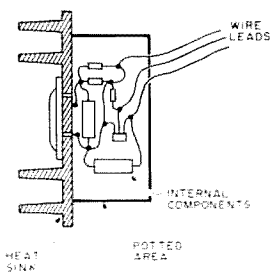

Fig. 1(c). An assembly with heat sink attached.

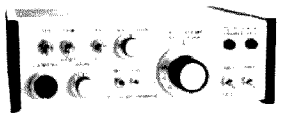

You will need some type of mold to hold the potting material while it is curing. I have used ice-cube trays, tin cans, small cardboard boxes, and plastic cases. Some can be break-away and others can be reused. Make sure the sides of the mold are coated with clear silicone grease to make extraction easier.

Figs. 1(a), 1(b), and 1(c) give some additional hints you can use for your modules. If you goof, remember that before the module has its final inspection, it can be filed, sanded, and painted. Any voids can be repaired with a second pour of additional material. A completed module can really look professional. Your friends will be asking where you bought that "special part" for your project. Happy potting! ■

AMATEUR TELEVISION

NEW 70 CM ATV TRANSCEIVER

ALL YOU NEED IN ONE BOX

$299 delivered
TC70-1

- **FULL COLOR, SOUND, & LIVE ACTION** just like broadcast TV. Get on this exciting amateur video mode at our affordable ready to go price.
- **WHAT IS REQUIRED FOR A COMPLETE OPERATING SYSTEM?** The TC70-1s downconverter outputs to any TV on ch 3 for receiving. Connect a good 70 cm antenna and low loss coax. Plug in any composite video source you want to transmit: Camera, VCR, computer, etc. Plug in any low Z dynamic mic or use color camera mic for Standard 4.5 mHz TV sound. Connect to 13.8 vdc for base, mobile, or portable. See chapt. 20 1985 ARRL Handbook. That's it!
- **WHAT CAN YOU DO WITH THE TC70-1 ATV TRANCEIVER?** Show the shack, projects, computer program listings, home video tapes, repeat Space Shuttle audio and video if you have a TVRO, repeat SSTV or RTTY, Weather Radar, do public service events such as parades, marathons, races, CAP searches and rescues... the list goes on. DX depends on antennas and terrain, typically 1 to 40 miles. We have video compensated RF linear amps for 20 ($119) or 50 ($189) watts pep for greater DX.
- **FEATURES:** Small 7x7x2.5". Push to Look (PTL) T/R switching. GaAstet downconverter tunes whole 420-450 mHz band. Two switch selected video & audio inputs...RCA phone jacks and 10 pin color camera jack. Xmit video monitor output. Over 1 watt pep RF output on one or two (add $15) selected crystal controlled frequencies. 439.25, 434.0, or 426.25 mHz.

CALL OR WRITE FOR OUR CATALOG for more info or who is on in your area. We stock antennas, modules, and everything you need on ATV.

TERMS: Visa, MC, or cash only. UPS CODs by phone or mail. Checks must clear bank before shipment. Price includes UPS surface shipping in cont. USA; others add 3%. Transmitting equipment sold only to licensed Tech class or higher amateurs, verifiable in 1985 call book or copy of new license.

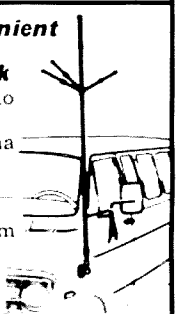
PACKET POWER

The hottest trend in Amateur Radio today is PACKET. It is error free communications and involves linking a special converter called a TNC (Terminal Node Controller) with a transceiver or receiver and your computer. With a TNC you can copy RTTY, AMTOR, CODE, or PACKET communications. Madison offers both the AEA PK-64, PK-80, or the Kantronics Communicator II, all priced at $229.00. (CALL FOR YOUR SPECIAL PRICES)



POLICIES--MASTERCARDS, VISA or C.O.D.
All prices FOB Houston, Texas, except as noted. Prices subject to change without notice, subject to prior sale. Used gear sale price refunded if not satisfied. Call anytime to check status of your order. Texas residents add sales tax.

Spider™ Antenna
U.S. Patents 4349825, 4460896
They are your assurance of quality and performance

Is Factory Pre-Tuning Good? No—It Just Does Not Work!
Every HF mobile installation has its own characteristics, and the antenna must be tuned to fit them. Only the Spider™ Antenna with its *patented tuning sleeves* can be tailored by the user to fit his own requirements. If the antenna is later moved to a different installation, the Spider™ can always be re-tuned as needed.
Beware of Cheap Imitations!

The Most Convenient Antenna for Mobile Work
No more stopping to change coils. Once the Spider™ Antenna is tuned for 10, 15, 20 and 40 (or 75) meters, just switch your transceiver from band to band—the antenna will follow by itself.

The Basics of Computer CW

Here's a twist: W9ODK preprocesses Morse to make life easier for his VIC-20. The result? A Basic program that copies code from 5 to 50 words per minute.

Anyone who has tried to write a Basic program to receive Morse code knows that the primary problem is speed. A very simple program can be devised to copy at speeds up to about 30 wpm, but its capabilities are severely limited. Adding such niceties as automatic speed tracking and some rudimentary error checking results in a top speed of only 10 wpm. I find it hard to be impressed with a computer that copies code more slowly than I do.

There seem to be two ways around this problem. Write the program in machine language (not easy with the VIC-20 and an alien language to most casual programmers) or devise a smart interface to go with a dumb program. The latter choice is a departure from conventional thinking regarding computers, i.e., using the "intelligence" of the machine to its maximum capability. This article describes an interface which makes all of the decisions concerning speed, length of character elements, and spacing between characters and words. The computer is required only to decide which character has been sent and then display it on the screen. This combination is self-adjusting for speeds from 5 to 50 wpm (top speed still limited by the Basic interpreter), is very accurate even under difficult conditions, and is very easy to use. It appears to perform as well as any hardware/software combination now available.

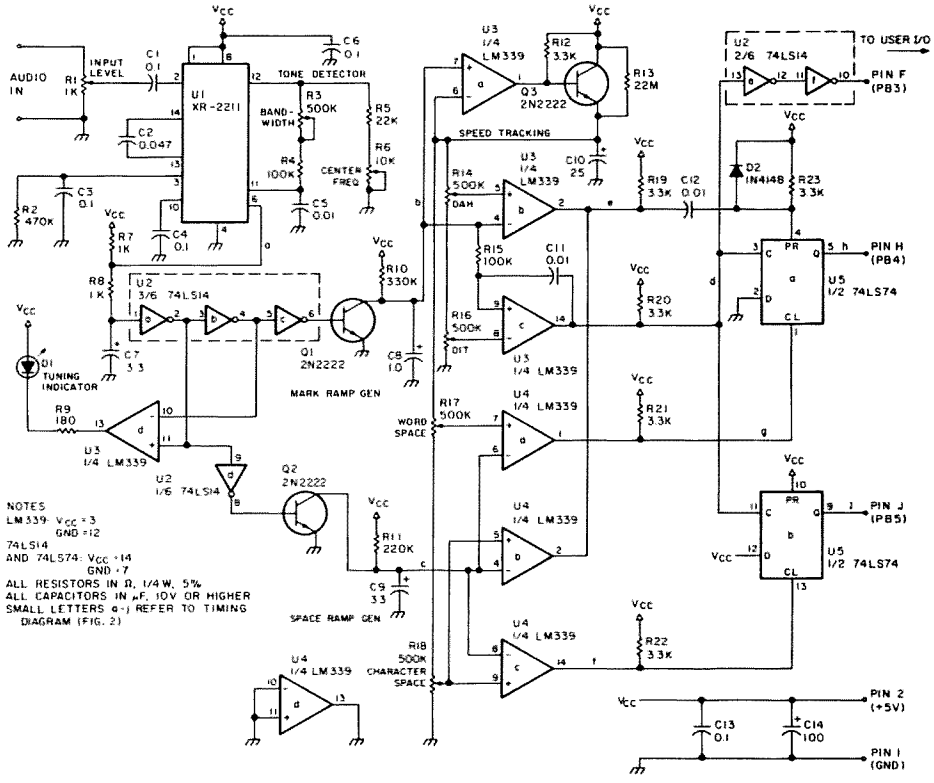

Fig. 1. Schematic diagram.

At first look, the schematic, Fig. 1, may appear complicated, but the circuit is really quite straightforward, using only five ICs, and it is easy to build and adjust. Total parts cost should be under $15.00.

Here is how it works: Audio from the receiver speaker is applied to the XR-2211 phase-locked-loop demodulator, here used as a tone decoder. Using the external components specified, it can be tuned from

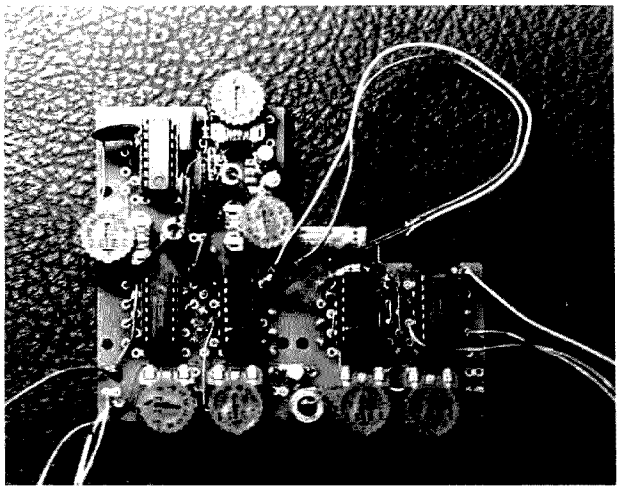

Photo A. The completed circuit board.

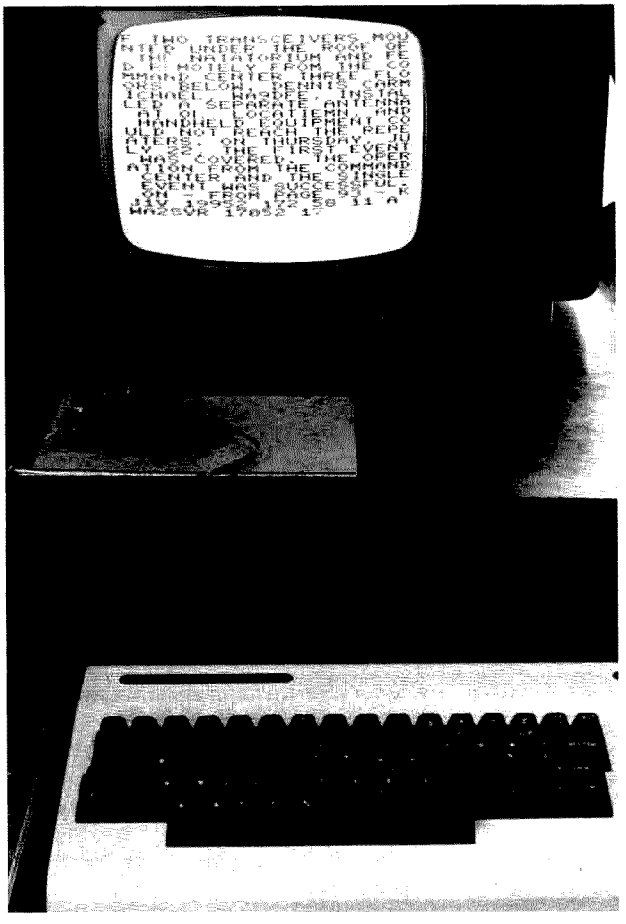

Photo B. Interface undergoing testing with W1AW code practice.

650 to 950 Hz and the bandwidth can be varied from 400 Hz down to about 70 Hz. The output from pin 6 is high when a tone is present. To prevent problems from noise spikes, the output of the 2211 is processed through an RC network (R8, C7) and several sections of a Schmitt-trigger inverter (U2).

Two separate voltage ramps are generated representing key down (mark) and key up (space). Refer to the timing diagram, Fig. 2. At slower speeds the ramps will rise to higher voltages, the rate of rise determined by RC networks R10-C8 and R11-C9. A peak-sensing circuit consisting of U3a, Q3, and C10 holds the highest level reached by the mark ramp generator. This becomes the reference by which character elements (dits and dahs) and spaces are determined. The speed reference voltage is established so quickly that only one letter need be sent before accurate copy begins. In fact, if the first letter starts with a dah, it will probably be displayed correctly.

A group of comparators, U3b–U4c, analyzes the two ramps to determine when a dit, a dah, a character space, or a word space has occurred. The outputs of the comparators control U5, a dual D-type flip-flop. There are four possible combinations of high and low levels from the Q outputs of the two flip-flops representing the above four events. Confusion could occur if there are two or more dits or dahs in a row, so a third signal line to the computer is needed. The output of the dit comparator, U3c, acts somewhat like a clock, telling the computer that a change has occurred.

Communication takes place through the user I/O port of the VIC-20. This port also supplies +5 V dc to operate the interface, so no other power supply is needed. Use of 74LS-series TTL and the low-power LM339 comparators keeps requirements within the 100-mA limit specified in the VIC-20 owner's manual.

What the computer does: The user I/O port, among other things, has a set of signal lines labelled PB0–PB7. See Fig. 3. These may be used as inputs or outputs; in fact, some may be inputs and others outputs at the same time. Referring to the program listing, the first line sets PB0–PB2 as outputs and PB3–PB7 as inputs. The interface is connected to PB3, PB4, and PB5. There are eight possible combinations of 1s and 0s on these three lines. Asking the computer to PEEK this port will result in a value between 192 and 248 in steps of 8. Four of

If moving, please give both your old address and new address.

these states are relevant and direct the program to calculate a value for the variable, D, which represents a particular character found in the string variable called LST$. When a character space occurs, it looks up the appropriate item in the list by means of the MID$ statement, prints that character, and resets D to 1. If a word space is received, it prints a space.

That's all there is to it. Because it's simple, it's fast. Incidentally, the ?s in the list just take up spaces and also make it likely that an error will appear as a ? in the text.

Getting it on the air: Building the circuit can be done however you wish using wire-wrap, point-to-point wiring, a universal prototyping board, etc. To connect it to the VIC-20, you will need a 12/24-pin card edge connector. A source for this connector is: Jameco Electronics, 1355 Shoreway Road, Belmont CA 94002. The only other connection required is to the speaker output of the receiver or transceiver.

```
10 POKE 37138,7
15 LST$ = "?TEMNAIOGKDWRUS??QZYCXBJP?L,FVH09?8????7
   #???/-61????*?@2?.?3?45????"
20 A = 1: B = 2: C = 8: G = 67: H = 48: IN = 192: M = 256: S = 37136
25 D = A
30 IL = IN
35 IN = PEEK(S): IF IN = IL THEN 35
40 ON (M-IN)/C GO TO 30,50,30,60,30,70,30,80
50 D = D*B: GO TO 30
60 D = D*B: D = D + A: GO TO 30
70 IF D>G THEN D = D - H: IF D>G THEN 80
75 PRINT MID$(LST$,D,A);: GO TO 25
80 PRINT " ";: GO TO 25
```

Program listing.

Adjustment is not at all critical. Start out with all the pots at half rotation. Connect the sidetone from an electronic keyer, CW keyboard, or some other source of accurately-spaced Morse characters to audio in. You may want to start copying code right off the air, in which case W1AW code practice is an ideal source. Higher speeds are more critical, so the 35-wpm practice is best for setup.

Begin by adjusting the tone detector. With the receiver tuned to match the transmitter sidetone frequency or whatever pitch you normally use for CW, adjust R6 so that the LED tuning indicator (D1) flashes in sync with the code being received. With the receiver volume at normal listening level, turn R1 down until the LED goes out, then advance it just until the light responds to the CW signal and not background noise. It is important to keep the input to the 2211 as low as possible for best signal-to-noise ratio.

Once the tone detector is set up, characters should start appearing on the screen. Adjustment of the pots on the comparator inputs is best done while listening to a good clean signal of machine-generated code at 30 wpm or higher. Begin by turning the dit pot (R16) both clockwise and counterclockwise until dits begin to be missed, then set it midway between these two points. Follow the same procedure for R14, R17, R18, and their respective functions. Once these controls are set for 100% reliable copy on machine-sent code, do not readjust them. Probably you can find a setting that will copy the sloppiest fist on the air, but accuracy on good code will be compromised.

The only pot you might want as a front-panel control is R3, the bandwidth adjustment. It could be set at maximum bandwidth (minimum resistance) for easy tuning and changed to a narrower passband for heavy QRM. The phase-locked loop in the XR-2211 does a good job of rejecting signals out of its lock range. An interfering signal can simply be tuned off the edge of the passband by adjusting the receiver tuning dial or transceiver RIT. A bandpass filter was tried in the audio input line but didn't seem to be necessary.

Where to go from here: The POKE statement in the program leaves PB0–PB2 as outputs. There is a reason for this, namely to allow one of these lines to key the transmitter when a sending segment is added to the program, thereby making the VIC-20 a complete CW terminal. Two *73* articles should start you on your way to developing this program: "Apple, Morse, and You," AF2M, July, 1983; and "VisiCode: The VIC-20 Way to Extra Class," W7LTH and KA7AQA, August, 1983.

This interface and program will work equally well for the Commodore 64. For the C-64 change line 10 to 10 POKE 56579,7. In line 20, change S=37136 to S=56577.

If you would like a cassette copy of a complete CW send-and-receive program for the VIC-20 or C-64 which features message buffers and random code practice with variable speed and character spacing, send $6.00 to the author (this includes postage). Be sure to specify which computer you have.

Computers are rapidly becoming a part of the ham shack, and the easiest place for you to start is with a CW interface. Combining the oldest form of electronic communication with the latest in technology lends continuity to the ever-changing hobby of amateur radio. ■

Terminal Teletype

The last RTTY program you'll ever type for your H-89.

Richard E. Levin W3RWU
Box 1085
APO NY 09283

After writing and using a Teletype® (TTY) program in assembly language, I was curious to see if MBasic, with its speed restrictions, would be able to do the same thing. This program is the satisfactory result of that quest. The program, operating at selected speeds from 60-wpm Baudot to 300-baud ASCII, will receive and transmit from the keyboard, write to or transmit from a disk file, send a canned message, provide a hard copy of received and sent traffic, and store received messages in a memory buffer.

Heath provided, with the 88-3 serial interface board, a simple way to interface a teletype terminal unit (TU) and other input/output (I/O) control functions. At the rear connector, P2, the TU is connected to pin 2 for data out and pin 3 for data in. Pin 20, the Modem Control Register, is used in this program to control the push-to-talk (PTT) of a transceiver. The first bit (bit 0) of port 220 (decimal), the Data Terminal Ready (DTR), is used for this purpose. The RS-232 levels of this port are used to control an optoisolator which in turn triggers a heavy-duty NPN transistor to key the transceivers, providing complete isolation of the H-89 computer from the "outside world." All RTTY control (except tuning) is done from the keyboard.

The Program

Line 390 initializes the Asynchronous Communications Element (ACE) for the desired baud rate and bit configuration as selected from lines 170–370 of the first menu. The H-14 printer is set up in lines 410–430. If hard copy is desired of either received or transmitted data, merely turn the printer on. Make sure the printer is on when you start

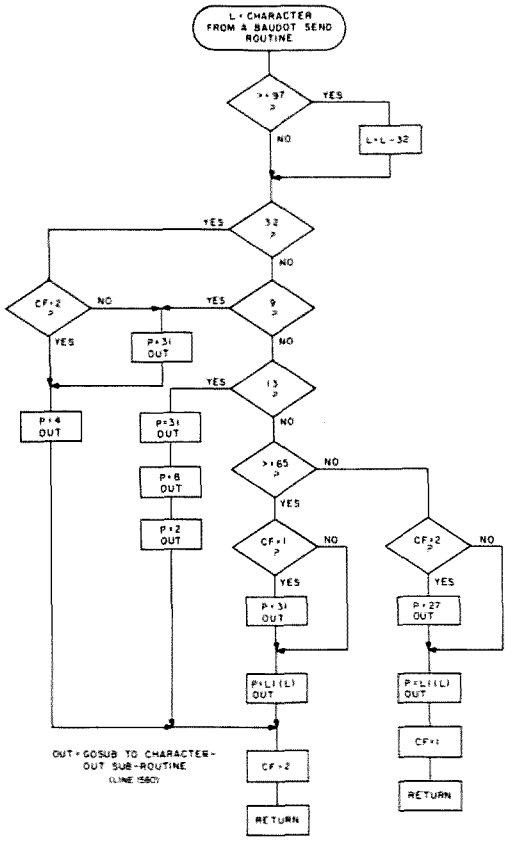

Fig. 1. Baudot send routine.

(RUN) the program. Line 300 sets a flag (FL) to 0 or 1 depending whether ASCII or Baudot is selected. Line 150 initializes a flag (CF) for Baudot upper- or lowercase. (2 = lowercase "letters.")

If Baudot is selected, lines 450–480 create arrays to convert ASCII characters to Baudot and vice versa. ASCII, of course, needs no conversion, so line 440 skips the arrays if ASCII is selected.

After selection of the mode/speed, lines 510–720 create the second menu, which will appear to the right of the first menu. Lines 510 and 710 turn the cursor off and on.

ASCII Receive

Lines 740–910 take ASCII characters from data-input port 216, print them on the screen, and send them to the printer port, 224. If during reception it is desired to store the message or any part thereof, striking a CTRL-K (ASCII 11) will place all incoming data in a memory buffer. Lines 880 and 890 accomplish this. Line 890 places the character in memory starting at address 38200 (decimal), increments once and inserts a decimal 255 (all bits "1"). Line 900 permits this buffer to extend to 56000, then resets to 38200, an 18K buffer. (If you have 48K RAM, the top should be set to 4000.) This buffer is not lost when returning to "SEND" or the menu, but to continue placing characters into the buffer after touching any key subsequent to the CTRL-K, it will be necessary to again hit the CTRL-K. This is because the last key struck remains in the keyboard port (232) until another key is struck. By the same token, striking any key after the CTRL-K (during receive) will halt placing characters into the buffer.

Line 780 checks the Line Status Register of the UART (ACE) to see if it is ready to accept another character. Bit 0 of this port (221) is set to logic 1 whenever a complete incoming character has been received and transferred to the receiver-buffer register of the ACE. If this bit is 0, line 810 loops the program back to line 780 and waits for the next character. In line 780, the byte from port 221 is logically ANDed with a one to toss out all but the first bit, bit 0. During this looping period, lines 790 and 800 check the keyboard to see if a CTRL-T or CTRL-D was struck to exit the routine.

The incoming-data byte is ANDed with 127 in line 820 to toss out the eighth, parity bit. This also has the effect of subtracting 128 from any received extraneous-noise characters between 128 and 255 decimal. Line 850 filters out these unwanted characters. Likewise, line 830 filters out a "form-feed" and line 840 gets rid of an "ESCAPE" character. Reception of an ESC followed by random characters can produce disastrous results. Line 860 prints the character to the screen and 870 sends it to the printer port.

Baudot Receive

The Baudot receive routine, lines 920–1200, has two loops—one for uppercase (FIGs) and one for "letters" (LTRs). The program jumps back and forth between them as it senses an incoming upshift, FIG character, line 1000, or a downshift LTR character, line 1130. The Baudot letters are converted to ASCII characters in line 1010, or Baudot FIGs converted to ASCII in line 1140. These conversion arrays were created from "DATA" in lines 3190–3220. Lines 990 and 1120 get the Baudot characters and AND them with 31 to toss out all but the five Baudot data bits.

Keyboard Transmit

Transmitting from the keyboard is accomplished in lines 1210–1360. Line 1220 turns the transmitter on, and the subroutine directed to in line 1230 is used at the start of all transmit routines. It provides a slight delay after turning on the transmitter and outputs two carriage returns and a line feed. The statement "INPUT$(1)" causes MBasic to read one character from the keyboard. P=ASC(X$) returns the ASCII code of X$ (line 1240). Line 1300 prints the character on the screen and sends it to the printer for hard copy (if the printer was turned on). Striking the RETURN key for a new line does not issue a line feed with this system. This is taken care of in lines 1310 and 1350. If the mode selected was ASCII, no conversion is required and the characters are sent to the output subroutine, lines 1580–1640. If Baudot was selected, then the characters are sent to the following subroutine.

Baudot Send Subroutine

Operation of this subroutine is best described with the aid of the flowchart, Fig. 1. The character flag, CF, has been set to 2 (LTRs) at the start of the program. ASCII characters from other routines enter as ASCII code integers, variable "L". The first line tests to see if they are lowercase ASCII (more than 97, beyond the range of conversion array L1, 0 to 97). If so, 32 is subtracted, making them uppercase ASCII. Next the character is tested to see if it is a "space." If so, a further test is performed to see if the previous character was a FIG or a LTR (Baudot). If both conditions are met, it sends out a Baudot space (4), sets the flag to 2, and returns. If the previous character was a FIG character, then a LTR (downshift) is sent before the Baudot space.

Next the program checks for a horizontal tab (ASCII 9). Tabs will not be processed, but a space will be

issued in Baudot. Line 1410 checks for a carriage return. If there is one, the program will send out a: LTRs, CR, and LF. If the character was not a CR, line 1420 makes the decision whether the character will be a Baudot upper (FIG) or a lower (LTR). All ASCII characters less than 65 will be Baudot FIGs. From here the previous character is checked for FIG or LTR by testing the CF flag. If the present character is different from the previous, with respect to FIG or LTR, the appropriate FIG or LTR shift is transmitted prior to the character. The ASCII character is converted to its Baudot code from the array in line 1440 or 1490. (DATA lines; 3220-3270.) If the present character is the same case as the previous, no shift command is given, the appropriate flag is set, and the program RETURNs to the proper routine.

Character-Out Subroutine

Timing speed (baud rate) is controlled by the UART (ACE). Lines 1590 and 1610 loop until the ACE is ready for another character. During this looping, line 1600 checks the keyboard for a CTRL-D to exit the routine and go to the menu. The CLOSE is there in case the EXIT was from reading an OPEN disk file. Line 1630 sends the character to the output port (216).

Transmit a File from Disk

Line 1710 reads one character from the disk file. Line 1720 returns the ASCII code of the character. HDOS/MBasic strips off all CRs when writing to a disk file. Line 1740 tests for this CR that the disk issues from sensing an LF. In this case, lines 1750 and 1760 will send out the required CR and LF.

The character is printed on the screen, and then the program loops back for the next character. Upon sensing the end-of-file (EOF), the file is closed and the program exits to the transmit keyboard.

RY Test and CQ Test

These are merely loops to read and send RYs (*U in ASCII) or CQ with a space. The end of these for-next loops drops to the call-sign loop, the DATA statement at line 330. These are ASCII codes for: "space DE W3RWU/5 space." Change this line of data for the call-sign of your choice. At the end of each line of test (or CQ), the keyboard is checked for a command to exit the loops and go to either keyboard send, CW ID, or the menu.

CW ID Routine

This routine uses the Line Control Register of the ACE to send a Morse CW ID. If bit 6 is set to a logic 1 (by sending a 64 to port 219), the serial-output ACE is forced to a space. When bit 6 of this port is set to a logic 0, it is forced to a mark. The data characters in lines 3280-3320 send my call. Three consecutive 64s are a dah, one 64 is a dit. Three consecutive 0s are a space between characters, and one 0 is the space between dits and dahs within characters.

This port (219) controls the bit configuration of the ACE, therefore it must be restored to its proper "BCON" at the end of this routine. Line 2300 sets the argument of variable B to this setting and 2380 puts B back into the port. Line 2410 is a delay to set the CW speed to about 15 wpm. Lines 2310 and 2320 put a reverse video message on screen, and lines 2360 and 2370 take the message off when the ID is finished and the program exits to the receive routine.

Write Buffer to Disk

This routine writes a simple sequential file to disk from what was stored in the buffer memory as loaded from the receive routine above. If the buffer is empty, line 2450 will vector the program to the "Buffer Empty" message and return to the menu.

Buffer Status Message

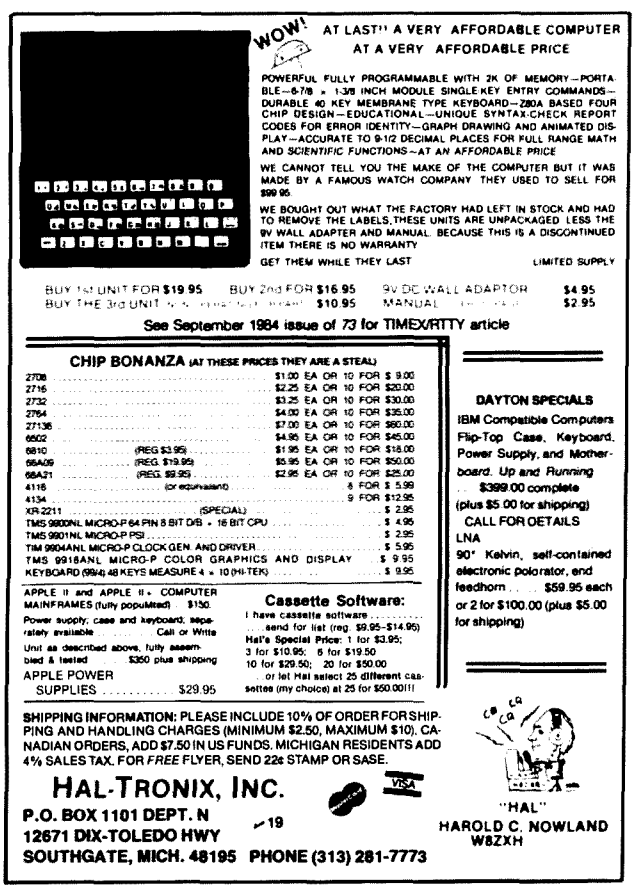
This routine is processed when anything is in the buffer as a result of a CTRL-K during receive. Variable I in line 2590 determines how many bytes are in the buffer, and lines 2610-2670 display this quantity on the 25th line.

This message will now stay on the 25th line until erased by selecting "8" of the menu or reading the buffer to disk (or re-RUN the program).

Read Buffer Routine

This routine will simply read back to the screen whatever is stored in the buffer.

Canned Message Routine



Here is a canned "brag" message that can be 256 bytes in length. The string X$ is the message and the @ will issue a CR and LF, although it is one continuous line in MBasic. Line 2980 reads the string one character at a time, and line 2910 tests for the end established in line 2890.

Empty Buffer Message

If the buffer is empty upon selection of 7, 8, or 9 of the menu, this subroutine will superimpose "No Message In Buffer" over the "SELECT NO." statement of the menu. This is accomplished using the direct cursor-addressing feature of HDOS.

This program should be easily adaptable to other machines using MBasic by appropriate changes to the commands and statements esoteric to the H-89, e.g., cursor addressing, screen blanking, port address, etc. Of course, the versatile features of the 8250 ACE are required for this program to work without timing delays.

Many thanks go to Dale Cockle K5JIC for his patient testing and helpful suggestions to get the program running.■

Malley's Manchester Monitor

Listen in on the world's finest conversationalist — you!

Over the past several years my Yaesu FT-101E has been modified rather extensively. This was due in part to an interest in improving the receiver section for contesting. The other factor was an uncontrollable need for its owner always to have a hot soldering iron in his hand. In any event, the radio gradually improved to the point where it seemed to play as it should from a competitive sense. However, a new feature became desirable during the past year—the ability to monitor the transmitter's audio in the headphones.

When the manufacturers initially introduced the monitor feature, it seemed more like another bell or whistle than the solution to a real need. Perhaps it still is, but I have found that there are several reasons that make this feature rather convenient.

The first hint of desirability came when I was operating a multi-operator/single-transmitter (multi-single) DX phone contest. We found that having boom-microphone headsets for both operators was invaluable when working split frequency on 40 meters. This is necessary since European amateurs cannot transmit above 7100 kHz. Here the monitor function allowed both of our operators to know when the other was transmitting. Another benefit was found when using a closed-loop CQ tape; there was less clutter involved in patching the tape-recorder audio into the operator's headphones.

You may be thinking that this might be great but if you're not a contester, who needs it? Well, I have found that there's something of a psychological boost to hearing your audio directly in the headphones during normal SSB operation. Also, commercial full-duplex FM headsets are used for communication in high-noise areas at work. These radios also have a monitor feature which the operators find really helpful.

Having determined the fundamental need for yet another convenience item, it became necessary to determine how to add it to the transceiver. The typical circuit in commercial amateur rigs involves diode detection in one of the i-f stages. This procedure was selected presumably to allow the operator to hear the actual transmitted audio quality. It is a relatively complicated method and one which some believe does not accurately represent what the receiving station actually listens to (because of propagation delays and the detection circuitry itself). These considerations led me to sampling at audio frequencies, which is basically quite simple. While this article presents installation details which specifically relate to the FT-101E, the modification should apply to many other transceivers with minor changes.

The audio unit in the FT-101E is designated PB1315. One output of this circuit board goes to the transmitter modulator/oscillator section (PB1184A). Oscilloscope measurements showed that this audio output level was insufficient to properly drive the headphones. Consequently, a simple IC amplifier stage was required.

One of the restraints that was placed on the design was that only a single supply voltage be necessary so that the +13.5 V dc in the FT-101E could be used. Another was that all parts be locally available. An LM386 met these simple requirements and is capable of supplying about 0.4 Watts of output power. This is a popular IC which has been used for the audio section of direct-conversion receivers. These receivers require a very high audio gain to offset their typical lack of an rf amplifier stage. This linear IC can be configured as either a 20× or 200× amplifier. For our purposes, the lesser gain is more than enough and requires slightly fewer parts.

The circuit for the monitor board is shown in Fig. 1. The audio input to the LM386 is supplied through a disc-ceramic capacitor and a potentiometer gain control. A voltage divider is provided at pin 6 to drop the transceiver supply voltage from 13.5 V to 8.5 V, which is approximately the midpoint of the 4-12-V-dc allowable range for the LM386. This voltage is bypassed with a 0.01-uF capacitor to keep transients out of the chip. Note: A 10-uF electrolytic capacitor can be connected between pins 1 and 8 *if a 200× gain were desired for another application.* In this case, the negative side of the capacitor is connected to pin 8.

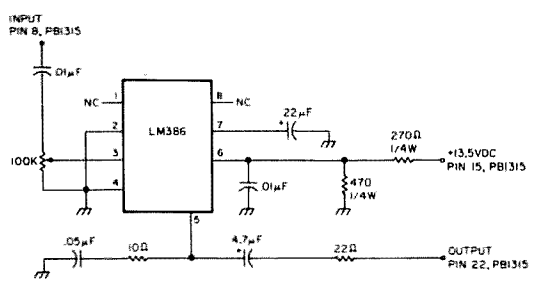

Fig. 1. The circuit for the monitor board.

The circuit can be assembled on a piece of perfboard or on an etched circuit board. Parts placement is not critical, although the bypass capacitor should be located as close as possible to pin 6. The PC board, foil side, is shown in Fig. 2.

Connect the monitor board input to pin 8 of PB1315 and the resistive divider to pin 15 or 16 of PB1315. The monitor output should be attached to PB1315, pin 22, which feeds the headphones. Miniature coax (RG-174) was used for these connections to eliminate any possibility of rf problems.

One of the more difficult problems encountered in modifying modern transceivers is finding a place to mount extra circuitry. I chose mounting the board on edge between the audio and modulator/oscillator units using one of the existing posts for support. This lets you adjust the amplifier gain if necessary and provides more space than that available under the rig's chassis. Once assembled, all that remains to be done is to talk into the microphone and adjust the pot until a comfortable audio level is heard in the headphones. It is advisable to turn the receiver's volume control off before setting this level since the receiver will be muted while you are transmitting. The monitor's gain pot is wired so that it can be turned off entirely if that should ever be desirable.

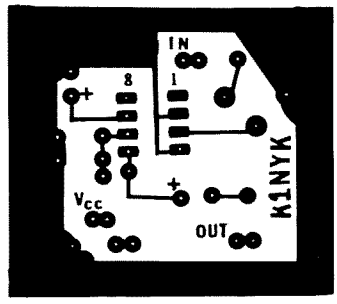

Fig. 2. PC board, foil side.

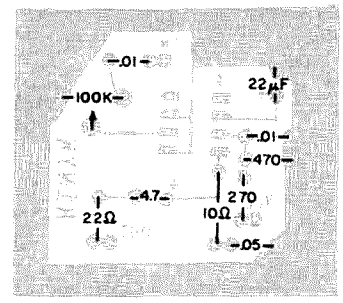

Fig. 3. Parts placement.

This is a simple modification that can be performed in a couple of hours at a leisurely pace. Thus, it is well suited for the newcomer to home-brew work. All parts can be obtained from your local Radio Shack store, as shown in the Parts List. Considerable variations in the electrolytic values can be made without significant effects. Likewise, the voltage divider can use other values as long as the voltage range noted above is not exceeded.

I have found that the monitor function has performed very well with good-quality microphone audio present in the headphones. Drop me a line if you have any questions on this modification (an SASE would be appreciated). ■

Dealers . . . SELL

Selling *73 for Radio Amateurs* will make money for you. Consider the facts:

Fact #1: Selling *73 for Radio Amateurs* increases store traffic—our dealers tell us that *73 for Radio Amateurs* is the hottest-selling amateur radio magazine on the newsstands.

Fact #2: There is a direct correlation between store traffic and sales—increase the number of people coming through your door and you'll increase sales.

Fact #3: Fact #1 + Fact #2 = INCREASED ALE, which means more money for you. And that's a fact.

For information on selling *73 for Radio Amateurs*, call 800-722-7790 and speak with our direct sales manager. Or write to *73 for Radio Amateurs*, 70/202 No. Peterborough NH 03458

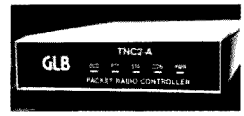
PACKET RADIO GOES PORTABLE

GLB ELECTRONICS
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight.
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement: 9 to 15 Volts DC @ 25 mA typical
Dimensions: 4.6 X 5.90 X 1.0 inches
Total Weight: 12 ozs



PKIL—Wired and Tested
List— $239.95
Amateur net— $209.95

GLB MODEL TNC-2A KIT

Just when you thought TAPR TNC-2 Kits were a thing of the past, GLB — the first commercial producer of Packet Controllers — Joins the "TAPR Revolution" at last!

GLB is now the exclusive supplier of TNC-2 Kits.

Easy Digital Circuit Analysis

Learn the basics of Boolean algebra while you design an electronic keyer. Then use K5VKQ's techniques to give your project a "software smoke test."

Got a computer you are trying to find uses for besides playing games? Want to sharpen your electronic skills for that upgrade? Or are you just interested in computers, period? Then here is another application for you. Try analyzing your digital circuits using your new (or old?) computer.

Microprocessors incorporate a set of logical operators in their instruction code. Basic interpreters and compilers usually incorporate these features also. Even if your Basic does not include Boolean operators, you can still analyze digital logic circuits with it.

I became interested in the application of the Basic language to the analysis of digital circuits about the time I got my computer up and running. As a working engineer, I am acutely aware of the tedious nature of defining the expected operation of a digital circuit by hand. The possibility of reducing the effort needed to define the operation of a circuit was sufficient encouragement to pursue the possibility of doing it by computer. Although custom circuit-analysis programs have existed for about as long as the electronic computer, their cost and availability exclude the average user. The application of Basic to the problem promised a method of analysis and also provided an excellent opportunity to better understand the Basic language itself.

Let us then proceed in the following manner: First, we will investigate the existing logical operators. Then, we will define equivalents for the brethren who do not have the Boolean functions. Finally, we will develop some additional logic circuits with applications. The logic (or Boolean) operators normally encountered in microprocessor languages include the OR gate, the AND gate, and the XOR (exclusive OR) gate. Additionally, an equivalent of the exclusive NOR, the NOT, and additional functions may be had. The usefulness of functions other than the OR, AND, and the XOR is questionable, as they may not be defined for binary logic and may produce results which are not expected. For example, the NOT function on my machine is a two's complement of the sum of a number and one. The answer comes out as a negative number. The best solution is to use what you have but make sure that what you have works. Generate (or look up) a truth table for the operation you are verifying. If it works, use it. If it produces weird answers, don't use it.

If you have any Boolean functions in your Basic, they are probably:

- OR—Used to OR two words together. We will limit our words to the numbers 0 and 1. Although the possibility of using numbers from 0 to 255 (for 8-bit words) makes 16-bit-wide input gates possible, one must crawl before one can walk.
- AND—Same as OR except it performs the AND operation.
- XOR—If you have it, it exclusive ORs two numbers.

If we write a simple program to illustrate the use of these functions, it will look something like this (for standard or ANSI Basic):

```
10 FOR A=0 TO 1
20 FOR B=0 TO 1
30 PRINT A OR B;
40 NEXT B
50 PRINT
60 NEXT A
```

If we run this short program, we will get a display which looks like this:

```
0  1
1  1
```

The first line represents the ORing of A and B when A is 0 and B is first 0 then 1. The second line is for A = 1 and B is first 0 then 1. This is indeed the correct result of the operation of an OR gate. If AND is substituted for OR in the above program, the display will be:

```
0  0
0  1
```

This is the correct result for the ANDing of two digital signals. In like fashion, the XOR operator produces:

```
0  1
1  0
```

The first operator we will define is the inverter. This is an absolute necessity if we do any TTL analysis. Fortunately, the function is easy to obtain. For applications where we wish to recognize the invert operation, we can call this INV. We can define the operation as:

```
10 INV(0)=1
20 INV(1)=0
```

The application of this is shown as Inverter Operation in Listing 1, lines 10 and 20, where it is used to change an AND function to a NAND function. Instead of the name

Listing 7.

INV, we could use N (or for that matter any symbol which the computer will recognize). The use of the N with AND or OR functions better enables us to recognize the NAND or NOR operations. (See Listings 2 and 3).

For those who don't have logical operators, we can develop what we need from the arithmetic operators. The easiest to derive is the AND function. Since it is the same (for 0 and 1) for both logic and arithmetic, we can use the multiply (*) operator. A AND B can then be represented by A*B. For A and B having values of 0 or 1, the only case where A*B=1 is when both are 1, which defines the AND operation. The NAND gate can be derived by inverting the AND gate as shown in NAND GATE (Listing 2).

To derive the OR and NOR functions, we need to remember the Boolean identity which states, "inverting the output of an AND gate is the same as inverting the inputs of an OR gate." Conversely, "inverting the output of an OR gate is the same as inverting the inputs of an AND gate." (You might remember that the next time you need one type of gate and you have only the other.) The NOR gate is the easiest of the two to derive since it is the invert of A multiplied by the invert of B (see Listing 3). The OR gate is the invert of the NOR gate (see Listing 4). If you don't have the exclusive OR function, you should remember that: A XOR B = (INV(A) AND B) OR (B AND INV(A)). The XOR gate can also be derived without the aid of built-in logical operators, as seen in Listing 5.

If you have the define function (DEF FN), you can use it to generate additional logic operations such as the ADDER (see Listing 6). Additional logic functions such as flip-flops, counters, shift registers, etc., rely less heavily on strictly Boolean operations. For example, the J-K flip-flop can be represented without any Boolean operators (see Listing 7).

In analyzing circuits using counters, flip-flops, shift registers, and other devices using clocked signals, you should incorporate some method to ensure that your program simulates the clocked operation. Some cases exist where no special care need be taken (as in the following flip-flop example):

```
10 INV(0) = 1
20 INV(1) = 0
30 CK = 0
40 Q = 0
50 FOR I = 1 TO 10
60 IF CK = 1 THEN Q = INV(Q)
70 PRINT Q;
80 CK = INV(CK)
90 NEXT
```

It is usually necessary to provide some method of ensuring that the true clocked operation is simulated. This is accomplished in the above example by use of the INV(CK). Since CK is 1 every other alternation, Q will invert every other cycle, simulating a by-two frequency divider. In most cases, however, this is not sufficient, as often some form of gate is used to interrupt the clock signal. The result of this on the above routine will be a continual flipping of Q if CK is gated to a continuous high. This can be circumvented fairly easily by the in-

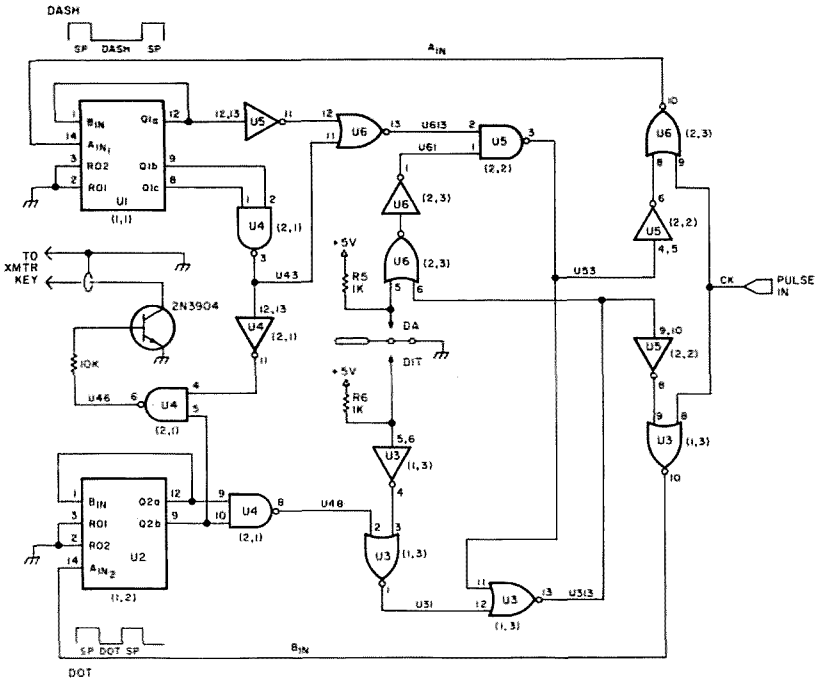

Fig. 1. Dot and dash generator.

Listing 8.

corporation of a gating function, as shown in Listings 7 and 8 (the E in the J-K flip-flop and the A in the D flip-flop). These slightly different approaches produce the same result; that is to prevent the output from flipping without the proper clock signal.

Proper gated operation can be accomplished by gating this signal as an enable or by gating CK. CK can be gated by adding a gate in the D flip-flop or by using B in the J-K flip-flop. Either an AND gate can be used (as in the J-K flip-flop) or an OR gate can be added.

The schematic (Fig. 1) is of an electronic keyer which I built some time ago. It uses a 555 oscillator as an input and generates an output with a dot-to-space-to-dash ratio of 1 to 1 to 3, with self-completing dots and dashes. Speed control is obtained by controlling the frequency of the 555 oscillator. The key is a typical single-pole, double-throw switch normally used on electronic keyers. (I made mine from a telephone polar relay which I obtained from a surplus store.)

To verify that the circuit performed as expected, I wrote the keyer program to simulate the operation of the keyer (Listing 9). The program-run shown under the listing is the simulation of the circuit operation for an output of "spaces," "dot," and "dash"—i.e., one dot or one dash. This verifies the self-completing nature of the dots and dashes and also the dot-to-dash ratio. It can be seen that four clock pulses are necessary to complete one dot. The dashes are three times the length of the dots or twelve clock pulses long. The oscillator must then run at four times the dot rate (twelve times the dash rate) to obtain the desired speed.

To simulate keydown operation, line 160 must be removed. This prevents the program from assuming a "space" when the clock goes low. In fact, it forces the program to assume that the input condition (dot, dash, or space) remains until directed otherwise. The program (i.e., circuit) continues to generate the proper dot-to-space and dash-to-space ratios when running either dots or dashes.

The initial (i.e., power-up) conditions are established in lines 10 to 100. Either random (lines 90 and 100) or predetermined (line 60) may be used to define the initial conditions. The ACP and BCP signals are introduced into the program to simulate the edge-clocked operation of the counters. Without this

function, the counter is not restricted to counting only when the clock is toggled; it will count as long as CK is 0 if this function is not present. This is accomplished by lines 270, 280, 290, and 330, 340. ACP and BCP are set to 1 each time through and can only be set to 0 when AIN and/or BIN are/is set to 1. This results in counting occurring only when the clock is toggling. This or a similar procedure is necessary whenever a clocked-type operation is simulated. Lines 110 through 370 simulate the actual operation of the circuit.

The system which I used to assign variable names was to use the device name followed by the pin number—for example, U310 corresponds to device number U3, pin 10. This procedure may not work with your computer, however. It may be necessary to choose simpler names to ensure proper circuit operation. Otherwise, the computer can confuse the signals; e.g., if the computer is capable of recognizing variable names only two or three symbols long, it will confuse signals U310 and U31. This is determined by the Basic which you are using, so know what your Basic is capable of before you start assigning signal names.

If you decide that you need an economical keyer and wish to build one, a parts list and description of the operation of the keyer is included. It is very simple in operation, requiring only a single control for speed (plus a switch if you want multiple ranges) and working on the assumption that a space is one unit long, a dot is one unit long, and a dash is three units long. The circuit can be constructed from common parts found in your junk box or purchased at your local Radio Shack store.

The dash generator is composed of U1, NAND gates U4 (pins 1, 2, and 3) and U5 (pins 1, 2, and 3), OR

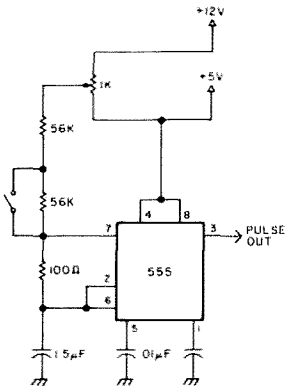

Fig. 2. Pulse generator.

gates U6 (two), and inverters U4 (output pin 11), U5 (output pin 11), and U6 (output pin 1). The dash circuit will toggle on power-up until QA, QB, and QC are all high. This will cause pins 11 and 12 of U6 to go low, driving pin 2 of U5 high. If the "paddle" is in the space or dot position, pin 1 will also be high. This will drive pin 3 of U5 low, which is inverted by inverter U5, driving pin 8 of U6 high, blocking further clock pulses to AIN. If pin 6 of U6 is low (more on that later), then moving the paddle to the dash position will cause pin 5 of U6 to also go low. This drives the output of the NOR gate high, which is inverted and drives pin 1 of U5 low. This results in pin 8 of U6 being driven low, which allows the clock signal (pulse in) to toggle U1 until the paddle is released and QA, QB, and QC are again all high. Additionally, until pin 3 of U5 goes low, signaling the end of the dash string, pin 11 of U3 will be held high, preventing the lower half of the circuit (dot generator) from functioning. The combination of the paddle being released and the necessity of QA, QB, and QC being high makes the dash self-completing.

In the truth table which follows, it can be seen that spaces occur during toggling when the count is 6 and 7, i.e., when pin 4 of U4 is high (pin 5 of U4 is held high as long as the dot generator is inactive). Since the

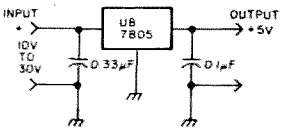

Fig. 3. Power supply.

total count is eight, and two counts are used for a space, the six remaining counts are reserved for the dash with a ratio of two to six (one to three).

7493 Truth Table

count	C	B	A
0	0	0	0
1	0	0	1
2	0	1	0
3	0	1	1
4	1	0	0
5	1	0	1
6	1	1	0
7	1	1	1

The dot generator is a simplification of the dash generator, requiring only the outputs QA and QB to generate the dots. As long as the paddle is held in the dot position, U3 pin 3 will be forced high, resulting in a low on pin 12 of U3. If the dash generator has completed its cycle, pin 11 of U3 will also be low. The resultant high on pin 13 of U3 will result in pin 6 of U6 being held high, blocking the dash generator, and pin 9 of U3 being driven low, allowing the clock pulse to toggle U2. Since the output is taken from QB, the dot-to-space ratio will be two to two (one to one). The dots will continue until the paddle is released and QA and QB are both high (i.e., the last dot is completed).

The pulse generator (Fig. 2) is a standard 555 circuit with minor exceptions. When varying the frequency in the normal manner, the resistance in series with the capacitor (the time-constant RC) is varied, which causes a nonlinear change in the charging current of the capacitor, forcing most of the frequency change to take place on one end of the control. By use of the potentiometer placed between the 12-V supply and the 5-V supply, the current supplied to the RC network will be linear. The frequency change will no longer have all of its change on only one end of the control. A decoupling capacitor (about 10 uF) can be connected to the center arm of the potentiometer to ensure maximum linearity, if so desired. Switch S1 can be used if desired to obtain a wider speed range. With the switch incorporated, the speed is about 5 wpm to 20 wpm in slow (S1 open), and about 10 wpm to 40 wpm in high (S1 closed).

The keying circuit is the output NAND gate, U4, the 10k resistor, and the 2N3904 transistor. This circuit was chosen to drive my Heathkit® HW-104 transceiver. If your transmitter requires a different keying method, you may redesign the output or insert a relay.

The 5-V supply (Fig. 3) is a 7805 regulator from the 12-V supply (most modern equipment is solid state and designed to run from 12 V). The .33-uF capacitor and the .1-uF capacitor are those recommended by the manufacturer when using the regulator.

As with all digital circuitry, a liberal sprinkling of decoupling capacitors should be used on the 5-V supply (one .1-uF capacitor at each device should be sufficient). Construction can be printed circuit if you care to lay out a board, or wire-wrap as mine is. I used 100-mil-spacing perfboard and wire-wrap sockets (both from Radio Shack) and wire-wrapped the circuit (using the little hand tool that Radio Shack sold me) when I was watching TV one night. The discrete components I mounted on a DIP header; I wire-wrapped a socket for them also. The cabinet is one of the small metal cabinets from the same source. You can either purchase a paddle or make your own as I did. If you have a surplus store in your area, look for a telephone polar relay. After the coil is removed, the remaining mechanical makes

an excellent paddle.

Incidentally, the above computer simulation discovered a quirk in the circuit that I didn't know existed until I ran the program. If the simulation is run in the continuous-dash mode without first running a space, the program will not toggle. If the keyer is powered up with the paddle held in the dash position (same condition as the simulation), the keyer will duplicate the condition first observed in the program.

Well, whether you build the keyer or something else, use the computer to simulate a circuit—or just read and forget. Have a happy QSO and 73. ■

Rock Solid Rf

Get pinpoint precision with this PLL-based frequency synthesizer.

Emil Ociepka
83-110 Tczew
ul. Matejki 2
Poland

The main problem radio amateurs face in constructing a receiver or transceiver is ensuring constant frequency of the receiver heterodyne or the transmitter frequency. It is not so difficult to ensure stable operation of a vfo operating on a relatively low frequency and within a fixed range. The problem lies in ensuring constant frequency of an oscillator which has to operate within various bands (10, according to the latest band plan) and on a relatively high frequency.

The problem may be solved by using switched crystal oscillators in the band generator or by using the PLL (phase-locked loop) method when constructing the band oscillator. The use of this method under nonprofessional conditions is difficult since the system is quite complex and involves the use of proper programmed dividers and a filter in the vco control system which is difficult to optimize and which has to operate over a large frequency range.

My solution is to use the FLL (frequency-locked loop) method for frequency stabilization of the band oscillator. The advantages of this method are a relatively simple system and the possibility of applying it to already-constructed equipment. The use of the FLL

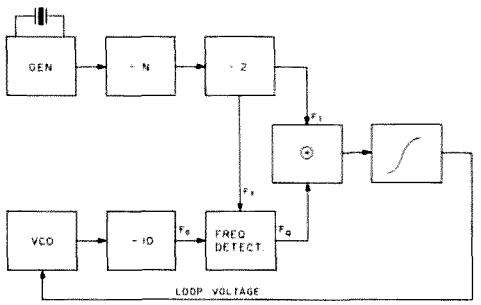

Fig. 1. Principle of operation of FLL synthesizer.

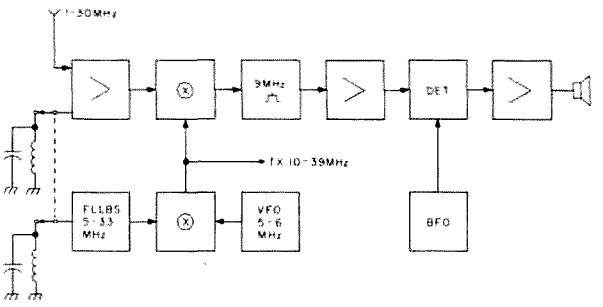

Fig. 2. Block diagram of radio receiver.

Received frequency F_R (MHz)	FLLBS frequency F_{H1} (MHz)	Vfo frequency F_{H2} (MHz)	Output frequency of heterodyne mixer (MHz)
1- 2	5.0		10-11
3- 4	7.0		12-13
7- 8	11.0		16-17
10-11	14.0		19-20
14-15	18.0	5-6	23-24
18-19	22.0		27-28
21-22	25.0		30-31
24-25	28.0		33-34
28-29	32.0		37-38
29-30	33.0		38-39

Table 1.

method for frequency stabilization of LC generators in the already-constructed equipment involves minimum system alterations while it considerably improves frequency stability.

Fig. 1 explains the principle of operation of the FLL system. The essential part is a flip-flop, type D, which functions as a harmonic mixer. Signals F_o from the vco and the clock signal, F_t, obtained from the quartz generator are supplied to its inputs D and C. The output signal of the flip-flop element, F_q, is expressed by the formula: $F_q = F_o - kF_t$, where k is a positive integer.

Obtaining the values of F_t and F_q as constants, we can change the frequency F_o in a function of the harmonic number k. In order to ensure constant frequency F_q, this frequency was compared with frequency F_t from the quartz generator. Both signals, F_t and F_q, are transformed into impulses with opposite polarization; added, their mean value is formed in the integrator, and they are amplified. From the amplifier output, the voltage of error is taken to adjust the frequency of the vco. Frequency F_q was, in my case, set at 50 Hz. Since frequencies F_t and F_q differ substantially, voltage levels F_t and F_q when added were also differentiated.

The Radio Receiver

The synthesizer constructed by me with the help of the FLL method is thought to be part of a radio receiver (and a transceiver in the future). A block diagram is shown in Fig. 2. As can be seen, the receiver system is of a conventional type. Single-frequency conversion was used with an i-f of 9 MHz. The vfo operates in the frequency range of 5 to 6 MHz. The receiver has ten bands. The determination of basic frequencies according to the formula $F_R = (F_{H1} + F_{H2}) - F_{i\text{-}f}$ and the determinations of the FLLBS synthesizer frequencies are given in Table 1.

The vfo is of a conventional construction: It is an LC generator. I intend to build a vfo also based on the FLL method, however. When constructing the whole receiver or transceiver, it is also possible to use the microprocessor vfos described in *73* (June, 1982); that output frequency is also 5-6 MHz.

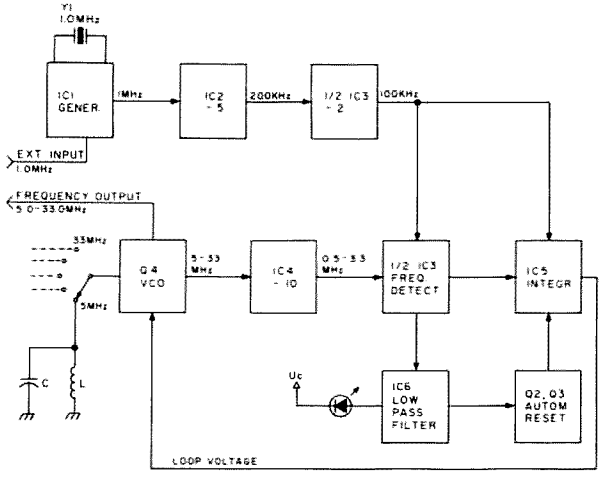

Fig. 3. Block diagram of band synthesizer.

The FLLBS Synthesizer

A block diagram of the synthesizer is presented in Fig. 3, while its schematic diagram is shown in Fig. 4 (digital part) and Fig. 5 (the vco). As can be seen from the drawings, the synthesizer is of a simple construction: All that is needed are several standard elements, and the cost of this system should not exceed ten to fifteen dollars.

The operation of individual parts of the system is as follows:

- The 1.0-MHz crystal oscillator is a typical one; it can operate on its own crystal or from an external 1.0-MHz generator.
- The next element (IC2) operates as a divider by 5; at its output (pin 11), a frequency of 200 kHz is obtained.
- The frequency detector (IC3) is based on a 7474 flip-flop. At its clock input (pin 11, IC3), a frequency of 100 kHz is supplied, obtained by dividing 200 kHz by the first flip-flop of IC3. To the input D of the detector (pin 12, IC3), a frequency obtained from the vco, preliminarily divided by 10 in the IC4 counter, is supplied.

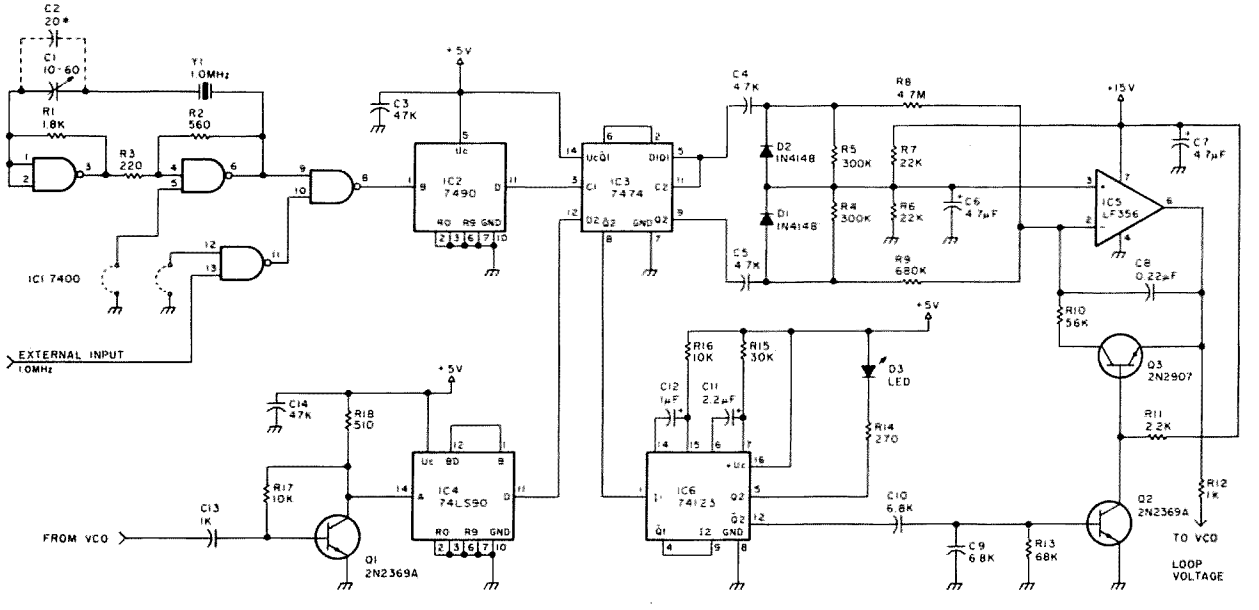

Fig. 4. Digital part of band synthesizer (FLLBS).

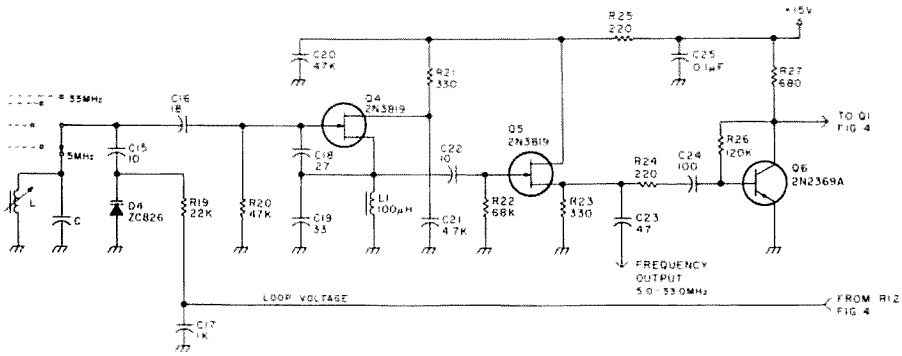

Fig. 5. Vco of band synthesizer.

- IC5 operates as an integrator; due to high resistances in the adding circuit, I constructed it with the use of an FET amplifier with high input resistance.
- IC6 functions as a low-pass filter; it has to detect and signal through the diode LED the state of desynchronization of the frequency-locked loop. Transistors Q2 and Q3 serve to neutralize the integrator when the vco is desynchronized and restore the state of synchronization of the loop.
- Desynchronization often takes place when changing the bands of the vco.
- The vco (Fig. 5) operates in a standard system. For individual operating bands (see Table 1), separate resonance circuits were used, changed by selector switch together with the corresponding input circuits of the receiver. The function of the switch may be also performed by contacts of relays. For tuning the vco, a varicap diode was used. At the generator output, a voltage follower from which the output signal is taken was used. The signal from the follower is amplified by transistors Q6 and Q1 and supplied to the counter from IC4.

Construction and Alignment of the FLLBS

The digital part of the system and the vco were placed on separate printed circuit boards. The purpose of this was to eliminate disturbing pulses from the digital part which could reach the receiver input through the vco. Depending on the actual mechanical design of the receiver, it might be necessary to enclose the digital part of the synthesizer in a shielded casing.

The vco, the voltage follower, and one stage of the amplifier were placed on a plate with the resonance circuits and the band-selector switch. Figs. 6 and 7 show the digital part of the synthesizer. The construction of the vco depends on the type of the band-selector switch used and the coil casing of the resonance circuits. The design of the vco PC board should be worked out individually, depending on the needs.

For the same reasons, I am not giving here the data for the LC circuits for individual bands; they should be selected according to the generally-known principles. All transistors and diodes used in my construction may be replaced by their more recent equivalents.

When aligning the crystal oscillator, pins 5 and 12 of IC1 should be properly connected. When working with a built-in crystal, pin 12 should be connected to ground and pin 5 left free; when using an external oscillator, it should be connected to the proper terminal pins of the PC board and pin 5 should be connected to ground, while pin 12 should be left free.

When aligning the synthesizer, a voltmeter should be connected to output 6 of IC5 and then controlling the vco frequency meter or a calibrated receiver, the vco resonance circuit of the vco should be tuned by means of the coil core to a fre-

SEE US AT DAYTON

quency close to the required frequency until the vco is synchronized. When synchronizing the oscillator, the LED should go out.

To obtain a maximum range of loop synchronization, the vco resonance circuit should be tuned in such a way that the voltmeter shows about 11 V. The above method of aligning should be repeated for all operating bands of the synthesizer.

Other Applications of FLLBS

The FLL band synthesizer described above operates with an interval equal to 1 MHz. In case it is used for oscillator stabilization with a different frequency interval, the frequency F_t should be selected accordingly. For instance, in a generator operating with an interval equal to 500 kHz, the frequency F_t should be reduced at output 3 of IC3 from 200 kHz to 100 kHz (IC2 should be changed so that it could divide by ten). No other change is needed.

When the FLLBS is used for oscillator stabilization in the already-constructed equipment, besides choosing the correct frequency, F_t, a varicap diode should be built into the existing oscillator through the correct padding capacity and the resonance circuits should be tuned into the loop synchronization range. The loop synchronization range depends on changes in the capacity of the varicap diode and the value of the padding capacitor, C15.

A capacitor with a relatively low capacity was used here to make impossible any accidental synchronization of the vco with the frequency different by ±1 MHz from the desired frequency. The operation of the vco and its synchronization were tested up to about 60 MHz; synchronization was correct within the whole range. If we want to use the FLLBS for operation at higher frequencies than 60 MHz, IC4 should be replaced with a fast-series IC. Capacitor C15 should be reduced and the vco resonance circuits should be selected and tuned; no other changes are necessary. ■

CONTESTS

Robert W. Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CONNECTICUT QSO PARTY
Starts: 2300 UTC April 5
Ends: 1900 UTC April 6

Sponsored by the Candlewood ARA, there is a required rest period from 0500 to 1300 on April 6th. Phone and CW are to be considered the same contest.

EXCHANGE:

RS(T), QSO number, ARRL section or CT county.

FRENOUENCIES:

Phone—3.927, 7.250, 14.296, 21.370, 28.540.

CW—40 kHz from low end.

Novice—3.725, 7.125, 21.125, 28.125.

SCORING:

Club station W1QI counts 5 points, Novice QSOs count 2 points, OSCAR QSOs count 3 points, others 1 point each. CT stations multiply QSO points by ARRL sections worked. CT stations may work DX stations for QSO points and only one multiplier, multiply QSOs by number of ARRL sections worked plus one DX country. Others, multiply QSO points by number of CT counties worked.

ENTRIES:

Include an SASE for results and mail entries by April 30th, addressed to: CARA c/o R. Dillion N2EFA, RFD #7, Noel Court, Brewster, N.Y. 10509.

CARF PHONE COMMONWEALTH CONTEST
Starts: 1200 UTC April 12
Ends: 1200 UTC April 13

This contest is open to amateurs in all countries of the Commonwealth of Nations. Entrants may work other amateurs in the Commonwealth using SSB only, on 80- through 10-meter bands. Work only stations outside your own call area. Each station may be worked once on each band. Entry classes include single-operator stations in all or single-band classes.

EXCHANGE:

RS report and a consecutive serial number, starting with 001.

FREQUENCIES:

3.600, 3.760, 7.080, 14.130, 21.200, 28.480 plus or minus 20 kHz.

SCORING:

Each completed contact will score 5 points. In addition, a bonus of 20 points may be claimed for the first, second, and third contacts with each Commonwealth call area on each band.

AWARDS:

A plaque will be awarded to the top scoring allband entry. Certificates will be awarded to top scorers in each class in each Commonwealth call area.

ENTRIES:

A valid entry must include log sheets, dupe sheets, a checklist of Commonwealth Call Areas worked on each band, and a summary sheet showing claimed QSO and bonus points as well as final claimed score calculations. Summary and call area checklist sheets are available for an SASE. Entries should be mailed within one month of the contest to: Norm Waltho VE6VW, Box 1890, 9714 94 Street, Morinville, Alta, T0G 1PG Canada. Results will appear in *TCA*, the Canadian Amateur Radio Journal. Nonmembers of CARF may wish to include an SASE with their entries for a copy of the results.

SOUTHERN CALIFORNIA SIX-METER CLUB QSO PARTY
Starts: 1200 PDT May 10
Ends: 1200 PDT May 11

The purpose of this contest is to generate and maintain a maximum of activity on the six-meter amateur radio band in any mode or form of communication. It is also to get as many hams as possible to mountaintop operate or otherwise provide strong signals for intercommunication within our area and, hopefully, nationwide.

If a good number of six-meter hams get out and on hilltops on the 10th and 11th of May, it will be quite a showing. Imagine the signals and signal reports of cross-confirmed contacts. Let's all get out or at least get on the air and have a good time. Make it a picnic on as many hilltops or high locations as we can radiate from. With a large contingent of Southern California six-meter hams we will hopefully stir the band up for some good sporadic E layer DX.

SCORING:

Based on one point per mode per callsign. Multipliers based on one per grid square worked.

EXAMPLE:

WA6BFH works N6FSL on SSB, FM, CW, and AM—for this BFH receives 4 points (one for each mode worked), also one multiplier for working grid square DM13. If BFH works K6GSX on all the same modes, he will receive four more points and one multiplier for working grid square DM03.

Key Clucks

NEWSLETTER OF THE MONTH

If you were asked to come up with a name for the Chicken Fat Organization's newsletter, what would it be? *Key Clucks*, of course! (CFO is a loose group of high-speed CW fanatics.) Editor Wayne Renard NZ4W carries the poultry theme to extremes; nearly every page of this newsletter has some sort of chicken on it.

Beneath the feathers lies a style of writing that made NZ4W famous as editor of the Nashville Radio Society's *Rat's Tale*. Wayne somehow manages to take the dull facts of day-to-day ham radio and turn them into hilarious stories. *Key Clucks* is proof that club newsletters can be informative *and* fun.

To enter your club's publication in *73*'s Newsletter of the Month Contest, send it to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: Newsletter of the Month.

ABOVE AND BEYOND

Peter H. Putman KT2B
84 Burnham Road
Morris Plains NJ 07950

This month's column is somewhat anecdotal. It pertains to all the careful plans that contesters put together for the big one—the January ARRL VHF Sweepstakes—and how, despite your best intentions, Murphy still has plenty of surprises in store!

I've been actively running the January SS for several years now, but have been plagued with all sorts of problems ranging from equipment failures to power line trouble and adverse weather conditions. Every year, despite the numerous station improvements, something "gremlin" rears its ugly head and I'm back to the drawing board. Well, this year was going to be different, with all-new antennas, feedlines, power supplies for the high power amplifiers, and improved transceiving equipment.

I took the perennial line noise problem into account and employed an ICOM 740S with adjustable noise blanker to fight the electric heaters and blankets on 144 MHz. (Believe me, it's no fun trying to copy FM06 through S9+20 dB noise levels!) Not being very active on 50 MHz, I secured the use of an IC-551D for the contest as well as a KLM 7-element beam. The 432 yagi array had been suffering from high swr after heavy rains which I traced to a marginal pigtail, and replaced with a more weather-tight version. A 220 MHz GaAsFET preamp went up on the tower, courtesy of the VHF Shop. What better way to test a preamp than during a VHF Sweepstakes?

I had earlier installed new runs of Prodelin 7/8" Spir-O-Line on 1296 MHz and also put a surplus Adler Electronics cavity amplifier to use for about 65 to 70 Watts of power. The SSB LT23S 1296-MHz transverter was run through a MMT 144/28 transverter into my Kenwood TS-430S, allowing the use of scanning and memory channels for setting up schedules. New tubes and capacitors went into the 432-MHz power amplifier to improve its reliability and every switch in the station was clearly labeled, for a change. (This latter part is very important, especially when you are frantically jumping from one band to another to make skeds on the UHF bands!)

Having completed the improvements to the station hardware, I turned to creature comforts. My shack is in the basement in an unfinished room, and the walls and floor are concrete. This is fine in the summer on a hot day, but makes an excellent refrigerator in the wintertime! A space heater in the right place took care of the heating problem (yes, it was prechecked for line noise) and I added several layers of foam insulation under a couple of pieces of carpet to keep the feet warm. A nice wooden chair with arms was selected for the long late night hours, and I installed low-angle lighting with 25- and 40-Watt bulbs to avoid eyestrain.

The last area needing attention was the logging and duping position. I secured the use of a Hewlett-Packard HP 110 minicomputer with companion disk drive and printer from Charlie Rothschild WB2INB. Charlie has developed a very nice logging and duping program that runs on HP and IBM/IBM-compatible systems, and our club group SCORE has used it many times during our multi-multi contest efforts. The 110 uses an LCD screen and is well engineered for human comfort while typing. The computer was set up next to the main 144- and 50-MHz stations, with the printer and disk drive on the side table for duping and backing up the memory during breaks.

The addition of a footswitch and selector to assign it to the three main transceivers allowed me to remain in one position. The output of the sequencer box also went to a four-position switch to key the 220, 432, 432 tube, and 1296 power amplifiers—again, all at the flick of a switch. Of course, the transverters on the TS-430 could be switched from 220 to 432 or 1296 through a selector panel, as could the CW keyer! My final act of laziness was to install another rotor with the 50-MHz beam and a second 32-19 Boomer for 144 MHz. This way, I could jump 180° at the flick of a coax switch to work stations calling me off the back of my primary antenna. (This isn't a new trick. Steve WB2WIK and others have used it for years. If you've got a few extra dollars and the tower space, it makes your 2-meter contact rate stay up there!) These modifications completed the upgrade of my station to make it contest ready.

Finally, all was ready. I'd booked the date in my calendar and the XYL made sure we had no plans for the weekend. (We actually did, except we didn't know it at the time. More on this in a moment!) The appointed hour rolled around on Saturday and at 2 pm KT2B was on the air on 50 MHz with 80 Watts.

It became apparent quickly that my 6-meter station wasn't going to make a big splash in the contest. Sure, the 80 Watts and the 7LD beam worked fine, but anything over 100 miles away was going to be VERY hard to work. The beam was installed at 30 feet, which is hardly optimum for 6 meters. But it was the only place I could install the beam, so I figured if I could add another 10 to 20 multipliers, it would be worth the trouble.

The IC-551 has a decent receiver but really needs a good preamp in front of it, so out came the JANEL MOSFET preamp that Mike Crawford WA2VUN had loaned me with the rig and beam. Only problem was we had blown out the MOSFET in June of 1984 during the June VHF QSO Party and he neglected to tell me that (or forgot). Out came the soldering iron and a new 3N204, and after a 15-minute delay I was back on the air. Some interesting prefixes were bagged during this period (nothing exotic) and I worked about 35 stations before turning to 2 meters.

Aha! Now this was more like it. The combination of the two Boomers—the main at 45 feet and the second at 35 feet—worked very well. With my 200-Watt MML amplifier (reviewed in March, 1986, *73*) I was able to start piling up the contacts right away. In short order I worked 70 or 80 stations and 10 grids! The 2-meter setup was working better than I had hoped. After several hours here, I broke for dinner and planned to attack the higher bands.

Soon I was back on 50 MHz checking for more new contacts and quickly added about 10 more before some incredible buzz in excess of +30 dB wiped out the front end of the IC-551D. Another electric blanket, probably. I jumped up to 220 MHz to see what was happening and fired off a few more contacts and grid squares—among them my first ever contact with FM28 on 220 MHz. We quickly jumped up to 432 to duplicate the contact, then to 144, and finally 1296 MHz (no luck). No matter! The station was really hopping now. I was finally appreciating all those hours of hard work during the summer and fall! 432 yielded more contacts and grids, including several in Maryland and southern Virginia. 1296 was even more fruitful with contacts into Maryland and northern Virginia. A quick check back on 144 MHz yielded many more contacts as stations wandered onto the band.

I took another quick break at 10 pm and went upstairs to grab a snack. My wife was looking a little funny and mentioned that she was having mild cramping sensations that evening. Unusual? Not if she's eight months pregnant. It seemed too early to be thinking of a baby! I had this strange sense of impending doom but shrugged it off and went back to work.

By now I was bouncing back and forth between 144 MHz and 1296 MHz (10 to 11 pm is the 1296-MHz activity hour in these parts) and working lots of stations. The total contacts were well over 200 and the grids in excess of 40 on all five bands. Not bad for 300 Watts on 144 and 432, 100 Watts on 50, and 220 on 70 Watts on 1296.

Activity tapered off on the higher bands so I went back to work on 50 and 144 MHz until about 2 am, when I decided to call it a night and get a few hours shuteye. I had made 250 contacts and 52 grids—decidedly better than my previous year's totals at the halfway point. In fact, I was running about double last year's score and well expected to break 500+ QSOs and 80 grids.

I knew I was in trouble when I came up to the bedroom and my wife was bent over on all fours on the bed, breathing slowly and looking at the clock. You guessed it! Her contractions had started and she was into active labor! I especially liked her comment as I came through the door: "I don't think you'll be going back on the air again this weekend!" To make a long story short, she indeed did wind up going to the hospital the next morning and by 5 pm we had ourselves a healthy 6-pound 5-ounce boy, three weeks early, and I'm sure it was because of my carefully laid contest plans! As she was wheeled into her hospital room, I pondered the meaning of it all. This had to be Murphy's

biggest prank ever, after all the blown GaAsFETs, shorted power supplies, and constant line noise. He's a resourceful guy! Makes you really respect him as an opponent. (And no, I didn't name my boy after him!)

As 8 pm rolled around, there was nothing left to do but go home, as Gayle was tucked away safely in her hospital bed, while Ross Lewis Putman was the subject of much admiration and attention of the nurses. Feeling like a fifth wheel, I was about to leave when my shocked ears heard my wife say "Gee, there's still a few hours left in the contest. Why don't you go home and operate them? It might relax you!" She had a point. Even though I hadn't had any sleep since early Saturday morning, the adrenalin was flowing like the mighty Mississippi. What the heck! A quick stop at Burger King, and I was home again, warming up the rigs.

News spread fast, especially when you've got guys like Steve Katz WB2WIK and Ivars Lauzums KC2PX in your contest club. I think every fifth contact included a "Congratulations, Dad!" with the grid exchange, not to mention a few expressions of surprise that I had actually bothered to get back on the air. Well, you just can't keep a contester down, and at 11 pm I pulled the plug with 290 QSOs and 58 grids for my efforts. It wasn't what I was hoping for, but I'll take it. . .

AM-6155 update: Well, Fair Radio is still out of stock on AM-6155s but is now getting rid of their AM-6154s at a fast rate. Many readers have called with questions on how to modify these radios for 2-meter operation! As they come from the box, they will tune the 144–148-MHz band, although you'll only see about 50–60 Watts out for 10 Watts of drive. I do not have any specific information on modifying this unit and would welcome it from readers who have done the mods. A suggestion might be to work from the 144-MHz mods to the AM-6155 from last month's column, as the plunger is reset on the 6155 to get 2-meter operation. The plunger on the 6154 is already set for it, so the grid compartment will have to be tweaked up. Basically, there are three places that will require attention: C1, the input coupling capacitor needs to be increased in value to about 10 pF. C2 and C3 will also have to be increased to about 30 pF and 100 pF respectively. (Refer to the schematic in the March column.) The existing output tuning circuits need not be modified to result in about 300–500 Watts with 1–10 Watts of drive, depending on how tightly you couple the input.

Again, I could use input from you readers. Send along your schematics and notes and I'll publish them posthaste. Incidentally, I ordered one of the #A5-TUN-CAV assemblies from Fair Radio and it showed up today, so I'll give a brief report on what I've found out so far: The unit does contain a 4CX250B and also contains a type 6816 tube, which won't be used. The input connector is a type SMA, and the hole it's in can be drilled out to take a BNC or N connector. The ouptut is type BNC and can be left alone. There are several adjustments, including a "PA FREQ ADJ" control, which resonates the cavity, and an output coupling control next to the tube using a flapper. The output of the 6816 also has a tuning control which could be used to resonate the grid of the 4CX250B.

Some kind of input grid circuit will have to be made up and I'll pass along my notes on this as I proceed. Although there is a hole marked "VHF-UHF PA BAND SWITCH," there is nothing in it so the cavity is tuned for one band range. I'll determine that also by the next column, but most likely it's set up for around 200 MHz. This unit also needs a blower and power supply voltages of +2000 VDC, +360 VDC, -135 adjustable VDC and 6.0 VAC for filaments. This might turn out to be a nice amplifier assembly, especially if you've got the power supply already built up. A single 4CX250B on 220 MHz should be good for around 300–400 Watts output with 2–6 Watts of drive. The cavity might also make a good repeater amplifier. The cavity design lends itself to a HI-Q tuned circuit, important in repeater installations to avoid desense. And 4CX250's are rugged and easily replaced. You can often find them at flea markets for as low as $10 apiece. Contrast that with 8930's which retail brand new for over $130!

READER INPUT DEPT.: Aside from the usual letters asking for more information on Fair Radio Amplifiers, I get newsletters from radio clubs. One of the strangest and funniest I've seen comes from the Pittsburg Repeater Organization and is called (appropriately) the PRO-Crastinator. Published by KC0ES, George Willard, it's a loose collection of local news, excerpts from the W5YI Report, and some funny articles on topics of general interest. This month's deals with the absurdities of mathematics in which the author proves that among other things, everything is white, and Alexander the Great did not exist while having an infinite number of limbs. What does this have to do with amateur radio? Beats me but I laughed pretty hard when reading the newsletter.

The Southern California Six Meter Club is sponsoring the Southern California Six Meter QSO Party on May 10 and 11. The purpose is to generate and maintain high activity levels on the six-meter band using any mode of communication. It runs from noon till noon PST, and entry forms are available from the club. Write them at: PO Box 448, Cypress CA 90630.

In future columns, I'll be discussing power measurements and tackle the subject of swr and what it means to you on the VHF and UHF bands. I'm also working on getting one each of the IC-471 and TS-811 multimodes for a side-by-side comparison in the lab. Many users of the 432-MHz band want full coverage of 430–450 MHz with the ability to work SSB, CW, and FM repeaters, as well as the OSCAR uplink. These rigs are full-featured and both will set you back a nice big piece of change. How well do they really work? Are they worth the investment? I'll try to have both qualitative and quantitative answers for you in the next few months.

Look for reviews of the new EME VHF/UHF wattmeters from Germany, including multiband models with coverage from 144 MHz all the way up to 2304 MHz. Also, more new transverters from Microwave Modules and SSB Electronics, as well as the Microwave Modules ATV transmitting and receiving converters. There're plenty of products out there for the VHF/UHF enthusiast and I'll try my best to have a look at as many as I can get for you. If you're out at Dayton this year, why not stop by the PX Shack booth and we'll have an eyeball QSO! Until next month, see you above and beyond!

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

I don't do this often, but in the spirit of this month's holiday, I hope you'll bear with me.

In the beginning, the Teletype Corp. created the Model 12, and it was good. Next came the Model 14, and it was good. Then came the Model 15, and it, also, was good. Soon thereafter came the Model 19, and it was *very* good. And then came the Model 28, and it was *very* good, indeed! But then came the Model 33, and it was the best yet. Ouch!

Well, you get the idea. Here I am with notes from many of you about the Teletype Model 33. Major Gene Pfeiffer of New York asks to be counted in, "at least 10 votes. I would like to do away with all unnecessary components. . . all I need to know is where I can cut in the external loop to drive the keyboard."

Louis Hutton K7YZZ of Bellevue WA is another ham who has tried to hook up a Model 33 to a computer. He has "been able to successfully modify the TTY to run from TTL ouput signals from the CoCo's serial I/O port. But like anything you try, there are problems."

Down south, Bob Furlong WD0CBN in Miami FL would like to hook up his Model 33 to use as a slave printer for his setup. He cautioned me in his letter that he has only "put together Heathkit projects and simple one-tube receivers, but I will give anything a try." That's the spirit, Bob!

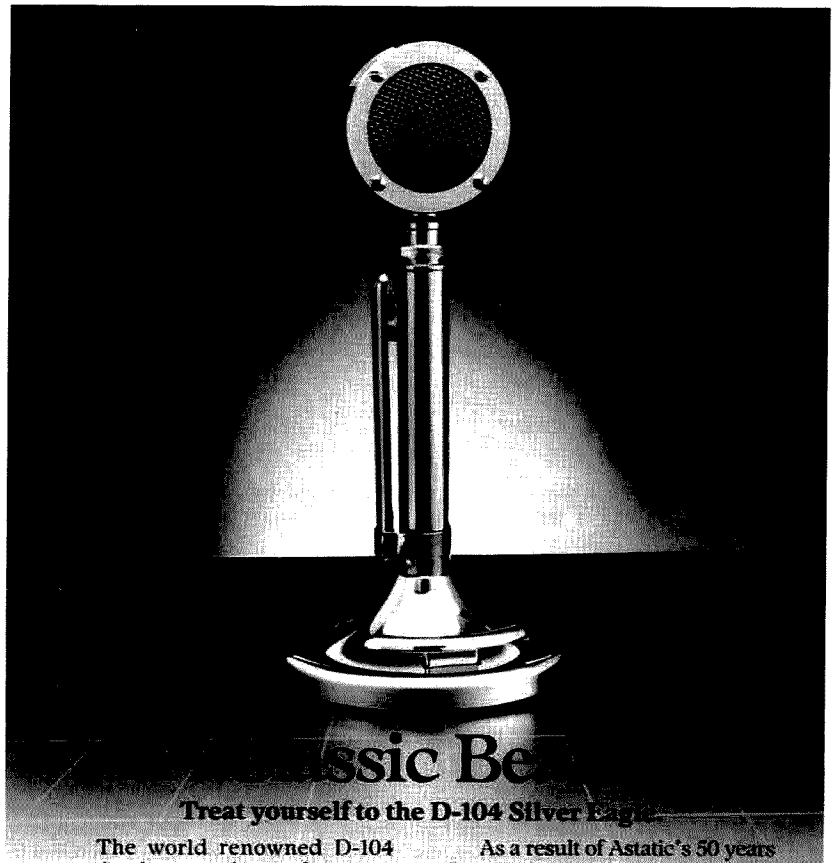
Ted Malafouris W9OVZ in Howell MI has used some of the information presented here before to hook up his Model 33 to a receiver, but says that all he prints is "garbage." Well, Ted, I'd like to remind you that the 33 is an ASCII-encoded machine, and most amateur transmissions remain Murray (5-level) encoded. Also, there is

tremendous variation in what FSK signals you'll encounter when tuning across the HF spectrum. Don't be discouraged—hopefully some of the material presented this month will help.

Andrew Janer WA1VRZ in East Haven CT is an ambitious soul who hopes to hook up a Model 33 to a Timex computer. We aim to please, sir.

The Teletype Model 33 teleprinter is either an electromechanical marvel or a nightmare, depending on how you look at it. Using a typing cylinder, kind of a "squooshed" Selectric ball, it chugged along at 110 baud—equivalent to 100 words per minute, ASCII code, uppercase only with a "Teletype standard" 72-character line length. Despite these limitations, many of these monsters found their way into amateur radio stations.

Interfacing the Model 33 is made difficult by the fact that there is no single standard version of the 33, but a variety of options contained in a panel on the right side of the machine, the Call Control Unit (CCU). Various CCUs were manufactured (the Model 33 is not out of production) for line service and telephone systems, as well as for computer interfacing. If you can get it, the I/O 33 is the easiest of all to interface. This CCU is identified by six push switches along the front of the CCU labeled MOTOR OFF, REMOTE, REQUEST, EOM, LOCAL, and PUNCH. Usually, that is. . .you see, there are different ones, too. And you can't always tell a CCU by its buttons.



Anyway, if you have one of those, you'll find a terminal strip inside, at the rear of the CCU. On mine, it was mounted vertically under the bank of Molex® connectors. On yours, who knows? If you have one like mine, connect the brown/yellow and white/blue wires to terminal 5, and the violet wire to terminal 9, and move the blue wire from the 750-Ohm tap to the 1450-Ohm tap on the power resistor behind the power supply inside the teleprinter. Then connect the interface through the connections shown in Fig. 1, after first checking for unwanted voltages and the like.

If you're a trifle less than brave, as I am (not), you might be interested in the circuit of Fig. 2. This is a scheme to use an optoisolator, such as a 4N35, to isolate the computer or interface from the deadly voltages that may be lurking around the Model 33. I highly recommend such isolation.

Let's say that you have one of those Model 33s that isn't equipped with an I/O CCU, now what? Well, you still should have the terminal strip, often labeled 151411, at the rear. If you lack that, trace out the wires coming from the selector magnets. They should enter a printed circuit board, the Selector Magnet Driver board. Pin 6 from this board should be ground; pin 11 is the signal input.

The wire going to pin 11, by the way, should be coming from the transmitter distributor. That means the keyboard signal should be available there. Again, if you have a custom-wired 33, all bets are off, but you should be able to trace out the wiring and go from there.

Assuming you have been able to identify the proper leads to connect to, and have interfaced the 20 mA TTY loop with the more

The world renowned D-104 stands alone as the performance leader in base station amateur microphones. The T-UP9-D104 Silver Eagle is also recognized for its outstanding beauty.

A bright, vibrant appearance reflects elegance and style. All exterior parts plus the base and handle are chrome plated to a jewel-like finish.

As a result of Astatic's 50 years of technology, this microphone is also extremely versatile. Factory wired, it can be easily converted to electronic or relay operation. Adjustable gain provides optimum modulation.

The D-104 Silver Eagle will make any rig look as good as it sounds. For more information, see your Astatic dealer or write.

common RS-232 levels of a computer interface, all that is left to do is make the computer speak 110 baud of ASCII. The ASCII part should be easy; it's the native language of most computers. As to the 110, it depends on the computer. We covered the CoCo in this column several months ago. Program 1 is a simple scheme to allow the CoCo to output at 110 baud through the "bit banger" serial port on the rear apron. Similar schemes should be just as easy for other computers. Even my old 6800 would slow down with the flick of a jumper.

I hope this material will help those of you who have been trying to get a Teletype Model 33 interfaced. Remember to measure all points for dangerous voltages *before* you hook up the computer. I don't mean you should take the "smoke test" literally! And please, let me know your experiences.

Moving right along. . . I have asked for some opinions, now and then, on a variety of RTTY topics. One of them has been packet radio. Are you interested, or will this be the NBVM (who remembers that one) of the future?

Wendell Larsen W3IRX of Upper Black Eddy PA has taken the challenge. Wendell says that he is "currently on HF and VHF RTTY with an IBM PC and Hamcom software" and has been contemplating getting on packet. No one yet has satisfactorily clarified his questions about this mode.

Wendell writes, "Essentially, what does it provide to justify the cost? Supposedly, it will enable countrywide 2-meter digital communication capability. I question this since it appears difficult, if not impossible, to establish effective links, at any time, even on the East Coast. I really can't see how error-free communication is possible if the link cannot be established.

"Now, packet operation on HF may hold some possibilities for point to point without intervening digi-peaters. I'm constantly hearing local 2-meter packeteers enthusiastically proclaim that they made it as far as New York or Florida. Even then, the path was so cluttered that nothing practical could be accomplished."

Well, Wendell, from the packeteers I've talked to, it sounds like we are looking at two different systems! I don't know what the closest digi-peater is in Upper Black Eddy PA but here in Baltimore establishing a link with a machine doesn't seem to be much of a problem. Now, I grant you, what hams talk about on packet is not likely to be any more stimulating than what hams talk about on RTTY, FM, SSB, AM, or CW. I am leaving ATV and SSTV out of this because they at least have pictures.

But the mode itself promises great potential, with the proliferation of digi-peaters. I think back to my early days on 2 meters. On AM, getting a signal from Silver Spring MD, a suburb of Washington DC, into "the District," (as residents term DC) was a real thrill. When the first FM repeater was established midway between Baltimore and Washington, I drove to a hill near my home to try to make the repeater, and with it, Baltimore. Now, 2 meter repeaters are so common that sitting here in my den I can pick up a handheld two-meter rig and trigger five or more machines, with a geographic range of Washington DC to York PA.

This is the ground floor of packet'dom. If it takes off, it won't be for present convenience, but for future promise. Let's hear what others have to say on the subject. We all would like to know.

Regards to David Berger WD6EUC of Sunnymead CA. David has joined the ranks of C-64 owners, and is looking for a way to put his computer onto RTTY. Well, David, I hope the review of C-64 and VIC-20 software covered here a few months ago was a help to you. I also suggest that you ask around at your local ham club for someone who uses this setup. The C-64 is a popular small computer, and I am sure that you'll find someone in your area who is using it on RTTY. Let me know how you make out.

Another fan, Jerry Valentini KC2IO of Jersey City NJ is running a TRS-80 CoCo, and is looking for a disk-based program to run RTTY. Well, sorry to say, Jerry, not much is available commercially at this time. A scheme was presented here a few months ago to convert Clay Abrams' program, NEWRTYCW, to at least load from disk, and I have sent that along to you. Hope it helps.

Jerry also asked about keyboard replacements, a topic that I have addressed for several computers. Well, if you can find it, the fabled $5 Radio Shack replacement keyboard certainly represents the best value per dollar ratio. You can identify it by the red BREAK/ESC key in the upper right corner, an ALT key next to the Q, a CTRL key next to the A, the CLEAR key next to the @, and the cursor arrows relocated to a diamond configuration on the right side of the keyboard. It also sports two function keys, labeled F1 and F2, at the lower right. If you can't find that one at Radio Shack, don't buy any of the other Radio Shack keyboards; they were made for a variety of other computers, and won't fit the CoCo.

Instead, you'll have to choose from the $5 keyboard being sold at a higher price, as advertised by several national advertisers, or one of the "expensive" keyboards that cost more than $50. At that point, it really becomes a matter of personal preference. To get a feel for typing on one, see if anyone near you owns any of the replacements. Good luck.

As you can tell, many of the folks writing in this month were helped by material presented in this column in the past. Many of the more requested topics are in the reprint series I have put together. A list of reprints, each of which is available for a self-addressed stamped and $2 to cover costs, can be had for the SASE alone. Just send it to me at the address at the top of this column, and ask for the list of available reprints. I always welcome questions, of course, and try to answer them in the column as soon as possible. If you want a personal response, be sure to include that all-important SASE. I can also be reached on CompuServe, ppn 75036,2501, either on EasyPlex or often on the CoCo SIG (GO COCO).

Topics are flying by these days, and next month promises to be a winner. Be sure your subscription to *73* is up to date; you wouldn't want to miss next month's RTTY Loop!

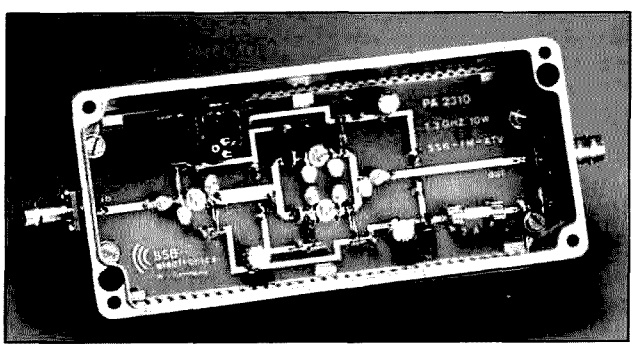
REVIEW

SSB ELECTRONICS PA2310 POWER AMPLIFIER

SSB Electronics of Iserlohn, Germany, is an up-and-coming manufacturer of many quality products for VHF and UHF enthusiasts. The company also offers a full complement of receive converters, transmit converters, transverters, and amplifiers for microwave enthusiasts. The PA2310 is a solid-state amplifier for the range of 150–1300 MHz, which operates from 13.8 volts and allows SSB, FM, or ATV operation.

Ordinarily, a low-power monoband UHF amplifier might not warrant much attention; however, there are very few available in the medium-power range for 23 centimeters. There are several transverters on the market for this band, but most of them are limited to 1 to 3 Watts output. The PA2310 complements those transverters, especially since it requires only 500 to 750 mW of power to attain full output.

Another reason it's handy to have 10 Watts of power here is that most outboard high-power 23 cm amplifiers utilize 2C39/7289/3CX100 type tubes, operating in grounded grid configuration. These amplifiers are usually good for 10 dB of gain in this mode, so 10 Watts of drive will usually yield 100 Watts or so of output. Use two of these tubes and you'll see close to 200 Watts output. The PA2310 fills the gap nicely as an intermediate driver stage, so you will see 100 Watts or more of output instead of 10 to 15 Watts using just the transverter.



The photo shows the unit with its cover off. The circuit is simple and employs three type BLU90's —one as a driver and two as finals. The output circuit is the usual etched microstrip type. Bias is set by the pot in the upper left corner. Note that there is no provision for standby operation, although you could incorporate it if needed. The amplifier operates in grounded-emitter mode and gain is typically on the order of 6–7 dB per stage.

SSB Electronics rates its amplifiers at 14.5 V dc, which is apparently common practice in Europe. How did this model do? With a Bird Model 43 Wattmeter and 25G slug (25 Watt, 1.1–1.8 GHz), I measured exactly 10 Watts output across a Termaline 50-Ohm dummy load. The driving source was a Microwave Modules MMT 1296/144, which was throttled back to about 500 mW output; the source voltage was 13.8 volts. Raising that voltage to 14.5 volts resulted in about 12 Watts of output power. Lowering the voltage to 12.5 volts dropped the output to 8 Watts.

In actual operation, I used this amplifier on Slide Mountain in June of 1985 with the MMT 1296/144. Our power source was a motorcycle battery, which started out at almost 14 volts and dropped to about 13 volts when we concluded our operation. The amplifier ran cool at all times. The heat sink should be adequate for 1296 ATV operation; however, I'd recommend reducing the drive and keeping the output power at 8 Watts or so in this mode. Note that the BLU90 transistors aren't swr protected, and there is no ALC circuit in the output. You must take caution not to load them into an swr of 2:1 or greater—otherwise, you might be waiting a bit for replacements from Germany. (At this time, there are no sources for this device in the United States.)

In my home station, I mounted a Dow-Key 12-volt coaxial relay atop the amplifier chassis. This amplifier switches the antenna lead from amplifier to transverter antenna input and also turns the dc power on and off to the PA2310. Again, some sort of switchable bias could be used and would accomplish the same thing.

All in all, the PA2310 is an excellent medium-power, reasonably priced amplifier for 23 cm. *Price: $300; U.S. distributor: The VHF Shop, 16 S. Mountain Blvd., Mountaintop PA 18707.*

The PA2310 solid-state amplifier with its cover removed.

55-ELEMENT ANTENNA FROM TONNA

Now that you've got some power on 1296 MHz, you'll need a good antenna to make the most of it. Along comes Antennes Tonna of France with a new wrinkle for 23 cm: a 55-element long-boom yagi. The boom is 15-feet, three-inches long and the manufacturer claims 21.25 dB gain over an isotropic dipole. Now, that's a lot of antenna!

The antenna comes completely disassembled with the various elements and holders in separate packages, unlike the 432 Tonna yagis that come largely assembled. But *don't* let the apparent complexity of the antenna scare you: Tonna has carefully color-coded the ends of the various elements so you can tell them apart. The elements themselves are made from #10 enameled wire that is filed flat but still quite sharp, so be careful. Select the elements by their color and push them through the one-piece molded element holders. You'll need a ruler, preferably one with a metric scale, to center the elements.

I have assembled two of these antennas and they both took about 2 hours of careful work from start to finish. Tonna includes an extra element in case you bend or break one. This *extra element is* as long as the reflector. As with all Tonna antennas, the drive element is a sealed dipole with a supplied RG-213 pigtail. On every Tonna antenna I've ever used (and that includes five 432 MHz 21-element yagis and four 1296 MHz 23-element types) the dipole-driven element exhibits better than a 1.2:1 match in the desired bandwidth. Not only is this an excellent matching system, but it's also very durable. There are no mechanical joints to corrode or work loose, and I wonder why more manufacturers don't use it.

You'll notice that the antenna comes with two boom braces. One problem with 23 cm yagis (and higher frequency yagis) is that the antenna mast support usually is a significant portion of the element length, and a 2-inch mast in front of one of these directors detunes the antenna quite nicely. Tonna recommends either mounting the antenna on top of a mast section, or using an outboard sidearm with the boom attached to the mast at its end. Since the elements stand off from the boom, mounting the boom at mast end ensures that the elements are sufficiently clear of the boom and mast. The top clamp makes this attachment, and the second, lower brace and clamp serves to level the entire antenna. As you might expect, the boom exhibits a bit of sag.

Once the antenna is assembled, you will probably have to break the boom at least in half to get it out of the door! I forgot the boom length and assembled the antenna inside forgetting that my door wouldn't allow the clearance to get it out!

The next order of business was to verify the claimed gain spec. Steve Katz WB2WIK of *CQ* magazine also received one of these monsters for evaluation, and he suggested we pool our efforts to set up a test range in which the gain figures could be verified. Steve did some research and came up with a formula from the publication "Technique of Microwave Measurements," from the M.I.T. Radiation Laboratory

$$G^2 = \left(\frac{4\pi R}{\lambda}\right)^2 \frac{Pr}{Pt} \quad \text{OR} \quad G = \frac{4\pi R}{\lambda} \sqrt{\frac{Pr}{Pt}}$$

G = Gain expressed arithmetically (not in dB)
λ = Free space wavelength in units
R = Range of separation of antennas in same units λ

Fig. 1. Formula for calculating gain of either of two identical yagis.

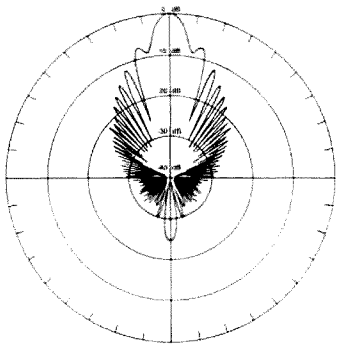


Fig. 2. The nomograph for the H-plane of the antenna.

series. The formula calculates the gain using two identical antennas that are a known distance apart. The formula is given in Fig. 1. Basically, all you need are two of the same yagi antennas and the ability to measure the distance between the two, as well as the power delivered to one antenna and the received signal from the other.

We set up the two 55-element yagis so that the front-most directors on each yagi faced each other at a distance of 75 feet (100 wavelengths at 1296 MHz). Using a Kenwood TR-9000 and SSB Electronics LT23S Transverter as a signal source, a Bird 43 wattmeter was put in the line right at the RG-213 pigtail, meaning it was about 1.5 feet from the dipole-driven element. At the receiving antenna, we mounted a Boonton 92 rf millivoltmeter with 50-Ohm probe and lots of Bunji cords. The power output was set at 5 Watts on the Bird 43 and allowed to stabilize for a few minutes. The rf millivoltmeter was also warmed up and set to the +20dBm range. Steve then swung the receive antenna back and forth slightly to peak the indicated output. At this point, the measurement taken from the millivoltmeter was +13.5 dBm (22.4 mW).

Plugging this into the formula resulted in a figure of 265.98 for both antennas. One antenna would exhibit 3 dB less, or half the gain: 132.99. Expressing this number as gain in dB would be 10 $\log_{10}$ 132.99, or 21.24 db. The manufacturer claims 21.25 db. Close enough for you? I would assume from this that Tonna's gain figures probably aren't overrated.

The pattern is very sharp. Fig. 2 gives the nomograph for the H-plan of the antenna. The 3 dB beamwidth is claimed to be about 11 degrees. The nomograph and our experiments would bear this out. The 55 element F9FT is a sharp antenna, and while it exhibits a considerable amount of forward gain, the sharpness of the pattern might make it unwieldy for the average 23 cm operator. Still, if you understand the antenna and its advantages and disadvantages, it can make the difference for your 1296 MHz station. For example, the K3YTL contest group used eight of these during the recent September VHF QSO Party and worked 65 stations on 23 cm. It definitely works!

The Tonna 55-element antenna costs $70. *US Importer: VHF Shop, 16 S. Mountain Blvd., Mountaintop PA 18707.*

MV 220 MAST MOUNTED GaAsFET 220-MHz PREAMP

SSB Electronics of Iserlohn, Germany, has become the first European manufacturer to come out with a commercially available mast-mounted preamplifier for 220 MHz. The 220 MHz band isn't available to Europeans and this represents an unusual bit of marketing on SSB's part. How much of a demand is there for 220 preamps? Only time will tell, but this is a big step in the right direction.

Based on the popular MV series preamps, the MV 220 is basically a reworking of the MV 144 mast-mount preamp. Employing a single GaAsFET, the manufacturer claims in excess of 16 dB of gain. This is considered a 1 kW through-line switchable preamp, and although the unit has its own rf vox type sensed keying, SSB strongly urges use of its companion sequencer when running high power levels.

I've always admired the rf and watertight cases in which SSB makes their preamps. A small gasket runs around the lip of the cover to keep moisture out. You'll need to make three connections: antenna, transceiver and dc power. As with all SSB preamplifiers, the coaxial relays switch in when power is applied. This protects the GaAsFET in case of power loss, or in the event of strong lightning storms. You just cut the power and it's out of the line.

Threaded studs are attached to the case, so you can bolt the unit directly up to a 2-inch mast. A small piece of tubing and gasket serve to waterproof the dc power connection cable, which you must supply. Installation is simple and takes only minutes. I used this preamp with my existing ARR sequencer for keying, and had no problems with false keying, although water got into one of the pigtails and froze, creating a high swr condition. It made no difference to the preamp as the GaAsFET percolated happily along.

On-air tests were impressive. 220 MHz is a sparsely populated band, and quite often the only signal you hear on it is weak and some distance away. In this case, the preamp makes a big difference, especially on signals with lots of QSB. In many cases, my basic 220 transverter—a "Canadian" Microwave Modules 220-28—couldn't even detect the signals that came up to S3 with the preamp switched in, largely due to the noise figure of the 220 module—around 2-2.5 dB. When working stations with rapid fading or flutter, the difference between hearing the conversation and hearing big gaps filled with noise was this preamplifier.

Okay, so it worked. But how well? Back to the lab: Using Hewlett-Packard test equipment, I measured the gain, minimum discernable signal (MDS) and 1 dB compression point. On-air tests indicated that this preamp had lots of gain, and the measured figure of 23.2 dB at 220.00 MHz certainly confirmed it. No doubt, this is one of the hottest preamps around—if you go by gain alone. What about MDS? In my tests, a signal of −140 dBm was detectable using a 1 Khz bandwidth. Pretty sensitive. A signal level of −130 dBm gave us a 10 dB S+N/N ratio, so it certainly hears the weak signals, not to mention putting my MMT 220 to shame. Well, what can you expect from a MOSFET at 220? A noise figure of 2.0 dB is not shabby.

I was surprised during the 1 dB compression test. This preamp does have lots of gain, and on-air tests indicated that the strong signal from Channel 13 was pumping the preamp adversely. By "pumping," I mean a general hash and splatter of intermod products head up and down the 220 band when my yagi was pointed towards New York City. Without the preamp, these products were unnoticeable. Incidentally, another preamp I use here (ARR 220 VDA) exhibits the same problem, but to a lesser degree. It uses a MOSFET and also has less gain. I didn't get to verify its 1 dB point but the SSB MV 220 came up short at -3.5 dBm out. What this means is that the preamp is likely to have trouble with strong local signals, on adjacent channels (and even on an adjacent TV channel) to the detriment of the weak signal you are trying to hear.

This isn't the first time I've observed a low 1 dB compression point on an SSB product. Another MV 144 preamp exhibited much the same number, but had lots of gain. Perhaps the compromise between gain and compression point still needs to be worked out by the folks in Iserlohn. Incidentally, the gain centers on 225.00 MHz, so this preamp could be employed for weak signal FM work as well on 223.50 with good results. In fact, the preamp still had 10 dB of gain at 210 MHz and 233 MHz—which is pretty broadbanded!

For those with a preponderance of weak signals on 220 to choose from, this preamp might make the difference. If you live close to TV channels 12 or 13, you may find the "pumping" problem to be a bit of a headache, but there is a provision to adjust the gain internally by means of a potentiometer. This pot is located at the input to the preamp and is part of a resistive attenuator network. The total attenuation is on the order of 5 dB. I haven't had a chance to use this control, but would be tempted to replace it with 10 dB of fixed attenuation and run the preamp at a net gain of 13 dB or so, which might help with the overload problem (and also raise the compression point above zero). I'll try to run these tests and report on them in a future "Above and Beyond" column.

SSB Electronics MV 220 GaAsFET Preamplifier, Price Class: $180; US Importer: The VHF Shop, 16 S. Mountain Blvd., Mountaintop PA 18707.

Middle Village NY 11379

PACKETEERING

I have seen the future and it is digital.

After several months of abject poverty, brought about primarily by the purchase of a home satellite TV system, I finally decided to take the plunge and invest in a packet radio terminal node controller (TNC). The result has been the most fun I've had in amateur radio since I gave the local repeater coordinator a hotfoot at the 1978 LIMARC hamfest and flea market.

Packet radio, fellow hams, is going to save our hobby. Don't let anyone else tell you anything different. I will be so bold as to predict that packet will become one of our primary operating modes by the end of this decade. It will certainly overtake CW in number of users and will be a rival to phone operation within a few years. Hams will still use CW for recreational purposes—just as some people occasionally like to ride a horse instead of drive an automobile—but packet is destined to become our primary method of transmitting text information. *Requiescat in pace* CW, RTTY, and AMTOR.

What makes packet communication so wonderful? Well, imagine being able to tie into international computer bulletin boards, to swap error-free messages and programs, and to have your computer send and receive data even when you're away or asleep. Who needs CompuServe, The Source, or those other high-priced on-line information services? Hams will do it better and for free. That is the heritage that has been handed down to us from the radio pioneers.

Packet, thankfully, is also relatively inexpensive. A $150 TNC connected to your existing 2-meter FM ricebox and home computer will put you in business. Heck, I've seen CW keyboards that cost more.

As you may have guessed, this month's questions are about packet radio. For those of you who aren't yet acquainted with the technology, I hope you'll read along. You may pick up some information along the way. As for packet veterans: the future is ours.

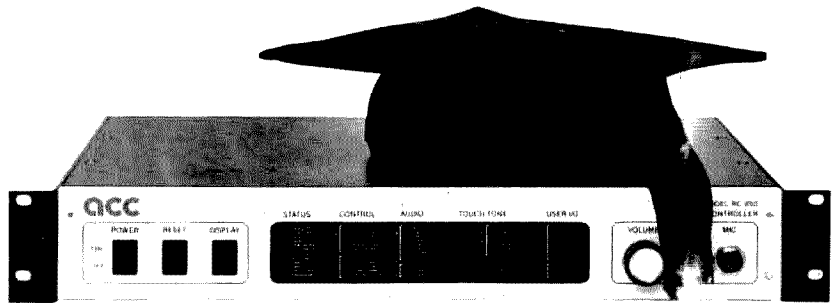
QUESTIONS

1) Packet radio sends data one character at a time.
   1) True
   2) False

2) A packet transmission *must* contain only ASCII characters.
   1) True
   2) False

3) A packet length is usually:
   1) 32 characters long
   2) 40 characters long
   3) 80 characters long
   4) 128 characters long

4) When were ASCII data transmissions made legal in the United States?
   1) January, 1970
   2) March, 1975
   3) March, 1980
   4) November, 1983



5) What is the maximum allowable baud rate below 28 MHz?
   1) 170 baud
   2) 300 baud
   3) 1,200 baud
   4) 2,400 baud

6) Above 220 MHz?
   1) 1,200 baud
   2) 2,400 baud
   3) 9,600 baud
   4) 56,000 baud

7) Approximately how many TNCs were sold during 1985?
   1) 100
   2) 1,000
   3) 10,000
   4) 100,000

8) Which of the following firms *does not* manufacture a TNC?
   1) Heath
   2) Kantronics
   3) AEA
   4) ICOM

"When You Buy, Say 73"

The RC-850 Repeater Controller just got a whole lot smarter.

Our new Version 3 software makes the best repeater controller **EVEN BETTER**.

The autopatch now supports remote telephone lines linked by radio, so that you can extend your autopatch coverage to match your RF coverage. You can have autopatch even if you can't get a phone line at your site. The 250 autodial numbers meet the needs of even the largest groups, with up to 35 digit storage for MCI and Sprint.

The easy-to-use Electronic Mailbox lets you include phone numbers, times, or frequencies as parts of messages. And it's so smart, it'll leave you a message if you miss a reverse patch, or if an alarm condition occurs.

Selective call and signalling capabilities range from two-tone sequential to numeric display paging, so you'll always be available. And its voice response metering is enhanced to continuously store low and high readings – so you can find out how cold it gets, how high the reflected power reads . . . and *when*.

Of course, a controller so feature-packed gives you **secure control**. Individual user access codes, with user callsign readback, can control access to selected functions to completely prevent horseplay.

ACC's amateur radio controllers are anything but "amateur". They're used by the U.S. Army, Navy, Forest Service, and other government and commercial users around the country. But, of course, you'll also find them on the leading amateur radio repeaters in North America and abroad.

There's never been a better time to upgrade your repeater system with an ACC controller, unmatched anywhere in quality, sophistication, and performance, with documentation and support to match.

Please call or write now for the rest of the story on all our repeater products, including controllers, digital voice storage units, and other Touch-Tone control products.

You'll be GLAD you did.

(408) 749-8330

9) Most packet activity is on:
1) HF
2) VHF
3) UHF
4) satellites

10) A packet network is a type of:
1) local area network (LAN)
2) database
3) communications protocol
4) telephone packet switching network

11) A primary packet channel is:
1) 146.52 MHz
2) 144.11 MHz
3) 145.01 MHz
4) 21.390 MHz

12) A digipeater is:
1) a dual frequency data repeater
2) a single frequency data repeater
3) illegal below 28 MHz
4) very expensive

13) A packet beacon runs continuously.
1) True
2) False

14) Which of the following *is not* a packet protocol?
1) AF2M
2) AX.25
3) VADCG

15) What city had the first U.S. digipeater?
1) New York
2) San Francisco
3) Boston
4) Los Angeles

16) A common serial interface is:
1) a Centronics port
2) an RX-7
3) hard to find
4) an RS-232C

17) AMSAT is planning to launch a packet radio satellite. It will be called:
1) OSCAR 17
2) PACSAT
3) DIGISAT
4) PACSTAR

18) TERRACON is:
1) another planned packet satellite
2) a ground-based packet linking system
3) a packet-based emergency warning system
4) packet for MARS operators

19) What *is not* useful in a packet beacon transmission?
1) Brevity
2) Name of operator
3) QTH or grid locator
4) graphics

20) Packet is allowed on Novice frequencies.
1) True
2) False

21) SKIPCON is:
1) an HF packet linking system
2) limited to speeds under 100 baud
3) an AMRAD project
4) all of the above

22) The TNC uses a bit-oriented standard known as:
1) an HDLC
2) an HLPT
3) a VADCG
4) an RS-232C

23) 1,200 baud is roughly equivalent to how many CW words-per-minute?
1) 60 wpm
2) 120 wpm
3) 500 wpm
4) 1,500 wpm

24) A TNC is roughly equivalent to what other type of computer peripheral?
1) modem
2) file server
3) terminal
4) printer

25) Packet is not allowed on 6 meters.
1) True
2) False

WHERE IS IT?

This is where the *73* staff would like to go after a hard day's work, or even an easy day's work, but we can't find it! We will give the first person to help us a year's subsription—or subscription extension—to *73*. *Mail* us, *in an envelope*, the full address and *identify the next-door sandwich shop!* Address: *73* Magazine Bar Contest, WGE Center, 70 Rte. 202N, Peterborough NH 03458. Earliest postmark will be the winner. Photo by Tedd Cluff.

THE ANSWERS

1—2 Data is contained in "packets" or bundles of data. A very frequency-efficient way to send information, since the transmitter is keyed on only when data is sent. And data is always sent at the fastest possible rate.
2—2 A packet may also contain such non-ASCII codes as Baudot or EBCDIC.
3—4 Helps to keep users from hogging a channel.
4—3 After years of lobbying by hams.
5—2 Band conditions and frequency constraints are the limiting factor.
6—4 Pretty fast.
7—3 Not a bad start.
8—4 But I bet you they eventually will.
9—2 Two meters, primarily.
10—1 Just a fancy name for a bunch of packet users.
11—3 Particularly on the east coast.
12—2 Almost any packet station can act as a digipeater.
13—2 It should come on every 10 or 15 minutes, at most.
14—1 AF2M is an Extra-class ham.
15—2 Ah. The old Silicon Valley crowd wins again.
16—4 The serial interface found on most personal computers.
17—2 A logical name.
18—2 TERRACON may one day link together all North American packet users through microwave relays.
19—4 Sort of a time and frequency waster.
20—1 But not by Novices, unfortunately.
21—4 HF may be unpredictable, but still useful.
22—1 High-Level Data Line Control.
23—4 Shows you how s-l-o-w CW is.
24—1 A very smart modem.
25—2 Although your neighbors may wish so.

SPECIAL EVENTS

COLUMBUS IN
APR 5

The Third Annual Columbus Amateur Radio Club Swapfest will be held Saturday, April 5, from 9 am to 5 pm at the Columbus IN 4-H Fairgrounds on SR 11 South. Talk-in on 146.790 repeater. For advance reservations write Chuck Roberts WD9DWI, 2950 S. Lake Drive, Columbus IN 47203.

ROCHESTER MN
APR 5

The Ninth Annual Rochester Area Hamfest will be on Saturday, April 5, starting at 8:30 am (setups on Friday from 4:30–6:30 pm). Sponsored by the Rochester Amateur Radio Club, Inc., raffle and drawings prizes include: Kenwood TR-2600 synthesized HT, Bearcat 20/20 programmable scanner, and a Ham IV rotor. Tables will be $8 each. In lieu of cash payment for tables you may donate prizes of at least equivalent value. In this case, prize certificates received will serve as advanced payment and reservation confirmation. For more information, write W.C. McGurk WBØYEE, 2253 Nordic Ct. N.W., Rochester MN 55901, or call (507)-288-7688.

MADISON WI
APR 6

The Madison Area Repeater Association will hold its 14th annual Madison Swapfest on Sunday, April 6, at the Dane County Exposition Center Forum Building in Madison WI. Doors will open at 7:30 am for flea-market sellers and at 8 am for the public. Admission is $2.50 in advance and $3 at the door. Flea-market tables are $5 in advance and $6 at the door. Talk-in will be on the M.A.R.A. repeater, WB9AER/R, 146.16/.76. For more information, write: M.A.R.A., PO Box 3403, Madison WI 53704, or call (608)-222-4744, day or night.

OLD BRIDGE NJ
APR 6

The Old Bridge Amateur Radio Association will hold an indoor/outdoor Electronics Flea Market, April 6, at the Knights of Columbus Hall in Old Bridge. The hall is located on Pine Street off Rt. 18 in Old Bridge. Talk-in frequencies are 147.120+600 and 146.520. Admission will be charged and a door prize will be awarded. Sellers may register by mail. Send SASE for details to Bob Navin, 106 Madison Ave., Old Bridge NJ 08857.

CLARKSVILLE TN
APR 6

The Clarksville Amateur Transmitting Society is sponsoring a swapfest on Sunday, April 6, starting at 9 am, at the National Guard Armory on Highway 41A in northern Clarksville. Amateur license tests will be given. Admission is free. Tables are $5.00 (single) and $7.50 (double). Talk in on 146.205/.805 or 147.43. For reservations or information, contact CATS, 1550 Armistead Drive, Clarksville TN 37042; (615)-648-3657.

TIMONIUM MD
APR 6

The Baltimore Amateur Radio Club will present the 1986 Greater Baltimore Hamboree and Computerfest on April 6 at the Maryland State Fairgrounds Exposition Complex at Timonium MD. Gates open at 8 am. The fairgrounds are located east of I-83 exit 17, three miles north of I-695, just north of Baltimore. Admission is $4, children under 12 free. For further information, contact: G B H & C, PO Box 95, Timonium MD 21093-0095, or call (301)-561-1282. For a recorded announcement, dial: (301)-HAM-TALK.

GROSSE POINTE MI
APR 6

The South Eastern Michigan Amateur Radio Association (SEMARA) will hold its 28th annual Hamfest Swap and Shop at the Grosse Pointe North High School, 707 Vernier Road, Grosse Pointe Woods MI, from 8:00 am to 3:00 pm. The Hamfest will feature an ARRL forum, DX forum, and a RTTY forum. Advance tickets $1.00, at the door, $3.00. Advance tables $8.00, at the door, $10.00. Talk-in on 147.75/.15 and 146.52. For more information, write to SEMARA Hamfest, PO Box 646, St. Clair Shores MI 48080, or phone Fred Lewis NK8M at (313)-881-0187.

KANSAS CITY MO
APR 11–13

The PHD Amateur Radio Association, Inc., will sponsor the annual Missouri State ARRL Convention April 11–13. Location is the old Kansas City MO airport, just north of downtown Kansas City MO. There will be commercial exhibits and 300 swap tables, all indoors. The banquet will be held Saturday night. Registration is $4 (good all 3 days), and swap tables are $10 (includes one registration). Banquet and swap tables should be requested in advance. Talk-in on 34/94 repeater. Registration and other information is available from the PHD Amateur Radio Association, PO Box 11, Liberty MO 64068-0011, or call (816)-781-7313 or (816)-452-9321.

SAGINAW MI
APR 11–12

The Saginaw Valley Amateur Radio Association, Inc., (SVARA) is hosting a State Convention for ham radio operators and computer buffs at the Saginaw Civic Center, April 11 and 12. NASA astronaut Tony England will be the featured speaker. For further information, write or call SVARA, PO Box 6662, Saginaw MI 48608, (517)-752-9740 or 776-1470.

BERWICK BICENTENNIAL
APR 12

The Columbia-Montour ARC will sponsor Special Event Station KC3TX commemorating the bicentennial of the city of Berwick PA. Operation will be in the General-phone portion of the 20- and 40-meter bands from 1700Z to 2400Z on April 12.Send QSL and $1 for a nice certificate to CMARC, PO Box 930, Berwick PA 18603.

GREENCASTLE IN
APR 12

The Putnam County Amateur Radio Club will hold its fourth annual Hamfest and Auction April 12, at the Putnam County Fairgrounds, north of Greencastle IN on US 231. Admission is $3 per person; children under 12 are free. Doors open for setup at 6:30 am, and open to the public at 8 am The auction is at 1 pm. Flea market space: our tables $3 each; your tables $2 each. Commercial exhibits welcome. Talk in 147.33/.93. For more information or table reservations send a SASE to Kent Douglas K9JCR, RR#4 Box 586, Greencastle IN 46135; (317)-672-8237, or Nick Aubrey N9FCB, RR#2 Box 592, Greencastle IN 46135; (317)-653-5290.

LAWTON OK
APR 12

Lawton Fort Sill Amateur Radio Club's annual event will be held April 12 at the County Fairgrounds, 8 am to 6 pm. This year the theme is "An Old-fashioned Swapfest." Registration fee is $2; table fee is $5; tailgate fee is $3. No pre-registration necessary except for table space. For more information, write Don Hagler, 912 Bell, Lawton OK 73505.

FRAMINGHAM MA
APR 13

The Framingham Amateur Radio Association will hold its annual Spring Flea Market and exams on Sunday, April 13, at the Framingham Civic League Building, 214 Concord St. (Rt. 126), downtown Framingham. Doors open at 10 am (sellers may begin setup at 8:30). Admission is $2, and tables are $10 (includes one free admission). Pre-registration is required for tables and exams. Talk-in on .75/.15 repeater. To reserve tables, write Jon Weiner K1VVC, 52 Overlook Drive, Framingham MA 01701, or call (617)-877-7166. To register for license exams, send completed form 610, copy of ham license, and a check for $4 (payable to ARRL/VEC) to FARA, PO Box 3005, Framingham MA 01701. Walk-in exams given on a space available basis.

BEDFORD PA
APR 13

The annual Southern Alleghenies Hamfest '86 will be held from 7 am to 4 pm on Sunday, April 13 at the Bedford County Fair Grounds in Bedford PA. (Pennsylvania Turnpike, Exit 11). Admission is $3. Plenty of tailgate space is available. Inside table spaces reserved at your request. A consignment auction will be held. Sponsored by the following clubs: Horseshoe Radio Club, Blue Knob Repeater Association, Bedford Co. ARC, Mountain ARC, and Somerset Co. ARC. Talk-in on 145.49/.89, 144.42/.92, and 146.52 simplex. For more infor-

mation, contact Gay Rembold W3DFW, 949 Winifred Road, Cumberland MD 21502, or call (301)-724-0674 or (814)-445-7486.

MOORELAND OK
APR 13

The Great Plains ARC fifth annual Northwest Oklahoma Eyeball & Swapmeet will be held in Mooreland OK on Sunday, April 13, starting at 9 am; $2 admission at the door. Covered-dish dinner at noon. Local airport. Dealer and swap tables available at no charge. Talk-in on 147.72/.12, 146.13/.73 and 146.52 simplex. VE test given on Saturday, April 12. Campsites available. Directions: North on Main or Elm streets, across the tracks and west. For further information, call (405)-994-5394 or contact Gordon Richmond NR5L, Rt. 1, Box 12, Mooreland OK 73852, (405)-994-5453; or Gerald Bowman N5CCV, Box 356, Mooreland OK 73852.

TASTE OF ATLANTA
APR 18–20

The Metro Atlanta (GA) Telephone Pioneers Amateur Radio Club (MATPARC) will operate special station W4OTA during the Taste of Atlanta food festival April 18–20. Operation on Friday and Saturday will be from 1500Z to 0300Z, and the station will be on Sunday from 1700Z to 2300Z. Frequencies are 7.285, 14.285, 7.055, 14.055, 144.81/.41, and 449.150/444.150 MHz. A special QSL is available for an SASE sent to MATPARC/Taste of Atlanta, John C. Parker, PO Box 54017, Atlanta GA 30308.

SOUTH SIOUX CITY IA
APR 18–19

The Midwest Convention of the ARRL will be held at the Marina Inn in South Sioux City IA on April 18 and 19, under the sponsorship of the 3900 Club. The convention will feature forums and an indoor flea market, and commercial exhibitors will be on hand to answer questions on the latest equipment. Bring your 2-meter rig for a free "tune-up," courtesy of Burghardt Amateur Center. Volunteer exams will be given on Friday the 18th. Pre-registration information should be directed to Dick Pitner WØFZO, 2931 Pierce, Sioux City IA 51104. Flea market reservations should be sent to Glenn Holder KØTFT, RR#1, Hinton IA 51024. Further information can be obtained through Convention Chairman Al Smith WØPEX, 3529 Douglas St., Sioux City IA 51104.

GROTON CT
APR 19–20

The Radio Amateur Society of Norwich (RASON) will operate Croaker Memorial Special Event Station KA1IFG from 1700Z April 19 to 1700Z April 20 from aboard the submarine *USS Croaker* to commemorate the 42nd anniversary of its commissioning. Look for us on these frequencies: SSB—3.890, 21.290; CW—3.730, 7.130, 21.130. QSL with SASE to RASON, PO Box 903, Norwich CT 06360.

HAM AND YAM FESTIVAL
APR 19–20

The Johnston Amateur Radio Society will help celebrate the second annual Smithfield (NC) Ham and Yam festival with special event station KA4HAM. Operation is from 1400Z to 2400Z both days on 3.855, 7.230, 14.255, 3.708, and 7.110 MHz. For a special QSL and certificate send a large SASE to Mark Gibson N4MQU, PO Box 2084, Smithfield NC 27577.

SULLIVAN IL
APR 20

The Moultrie Amateur Radio Klub (MARK) hamfest, formerly held at Sullivan IL, will be held Sunday, April 20, from 8 am to 3 pm at the Coles County Airport, located between Mattoon and Charles IL on Rt. 16. The hamfest will be in a large, heated hangar. Admission is $2 advance, $3 at door. No extra charge for vendors, but bring tables. Talk-in on 146.655/146.055 or 146.52. Further information, write MARK, PO Box 79, Sullivan IL 61951, or call Vernon Jack K9SWY at (217)-728-7596.

CAMBRIDGE MA
APR 20

The MIT Electronics Research Society and UHF Repeater Association will hold its tailgate high-tech, computer, and amateur radio Flea Market on Sunday, April 20, from 10 am to 4 pm, at Albany and Main Street in Cambridge MA. Admission is $1.50. Free off-street parking for 500 buyers. Tailgate room for 200 sellers. In the event of rain, covered tailgate area will be available for all. Sellers: $5 per space (includes one admission). Setup 9 am. For space reservations or further info, contact Jamie at (617)-262-5090 or 253-2060. Talk-in on 146.52 and 449.2/.444.2 (W1XM/R).

BRAINTREE MA
APR 20

The South Shore Amateur Radio Club of Braintree MA will hold its annual indoor flea market on Sunday, April 20, at the Viking Club, 410 Quincy Ave., Braintree MA from 11 am to 4 pm. There will be tables available for $12 each, which includes one free admission if paid for in advance by sending the appropriate amount to Ed Doherty W1MPT, 236 Wildwood Ave., Braintree MA 02184. Tables will cost $18 on the day of the sale. Checks should be made payable to the South Shore Amateur Radio Club. Confirmation of check receipt will be sent; no cancellation refunds after April 16. The Viking Club will open to vendors only at 9:30 am. Entrance fee $2. Plenty of parking. Questions? Call (617)-843-4431, evenings.

DAYTON OH
APR 25

The Miami Valley FM Association will sponsor the 17th annual B*A*S*H, on Friday night of the Hamvention, April 25, at 7 pm in the Conference Center at the Hara Arena and Conference Center, Dayton, Ohio. There is no admission charge.

DAYTON OH
APR 25–27

The Dayton Amateur Radio Association, Inc., will sponsor the Dayton Hamvention on April 25–27, 1986, at the Hara Arena and Exhibition Center, Dayton OH. Admission, valid for all three days, is $8.00 in advance, $10.00 at the door. Banquet tickets: $14.00 in advance, $16.00 at the door *if available.* Ladies luncheon, $6.75. Advance sale deadlines: April 5 (Canada) and April 12 (USA). Roy Neal K6DUE will be the banquet speaker.

Giant Flea Market: noon Friday through Sunday. *All spaces sold out.*

Technical forums on: personal computer, packet radio, ARRL, AMSAT, antennas, RTTY, SSTV/ATV, FCC, electrical safety, and other topics. CW Awards—try to break the 72.5-wpm world record!

License exams: Novice through Extra, by reservation only. Send before March 29: completed form 610, a copy of your present license, and check or money order for $4.25 payable to ARRL/VEC, to: License Exam, Attn. Tom Holmes, 8830 Windbluff Pt., Dayton OH 45459.

Send nominations for "Radio Amateur of the Year," "Special Achievement," and/or "Technical Achievement" Awards, to Awards Chairman, Box 44, Dayton OH 45401, before April 1.

For further information, see HAMVENTION ad on page 23.

DAYTON OH
APR 25

The Dayton-Cincinnati chapter of the Quarter Century Wireless Association will hold its 1986 annual banquet on April 25, the Friday night of the Dayton Hamvention. Leland Smith, national QCWA president, will speak on "The Future of Amateur Radio." Happy hour is at 6:30; dinner is at 7:30 at the Imperial House, I-75 and Needmore Road. For tickets and information contact Bob Dingle KA4LAU, 657 Dell Ridge Drive, Dayton OH 45429. QCWA membership is not required to attend.

FITCHBURG MA
APR 26

The Montachusett Amateur Radio Association will hold Flea Market Saturday on April 26 at the Knights of Columbus Hall on Electric Avenue, Fitchburg MA. Doors open at 8 am for sellers and 9:30 am to 3 pm for buyers. Talk-in on 144.85/145.45 and 146.52. Admission is $1; tables $8 each. For table reservations send check payable to M.A.R.A., c/o James Beauregard, 7 Mountain Ave., Fitchburg MA 01420.

CEDARBURG WI
MAY 3

The Ozaukee Radio Club, Inc., will sponsor its 8th annual Cedarburg Swapfest on Saturday, May 3, from 8 am to 1 pm at the Circle B Recreation Center, Highway 60 and County I, in Cedarburg WI (20 miles north of Milwaukee). Admission is $2 in advance, $3 at the door. Four-foot tables are $3 each. Sellers will be admitted at 7 am for setup. For more information, send a business size SASE to 1986 ORC SWAPFEST, 101 E. Clay St., Saukville WI 53080.

ROGERS AR
MAY 3

The Northwest Arkansas Amateur Radio Club, Inc. will hold its Sixth Annual Hamfest on Saturday, May 3, at the Rogers Youth Center, 315 W. Olive St., Rogers AR from 8 am to 4 pm. Commercial exhibitors and flea-market tables, $2 per space, first come, first served (doors open at 6 am for exhibitors only). General admission free. Parking, eating establishments nearby; snack bar on premises. Talk-in on .16/.76, .63/.03 and .52 simplex. For more information, write Roy Milliren AF5W, 2014 S. 16th St., Rogers AR 72756.

STIRLING NJ
MAY 4

The TCRA Hamfest (Tri County Radio Association) will be held rain or shine on Sunday, May 4, from 9 am to 3 pm at the Passaic Valley Community Center off Valley Road, Stirling NJ. Free parking is available. Tables are $7, ac $10. Registration is $2. Limited tail-gating by reservation only please. All reservations through Dick Franklin W2EUF, Box 182, Westfield NJ 07090; (201)-232-5955.

MELVILLE LI NY
MAY 4

The Suffolk County Radio Club Indoor-Outdoor Electronic Flea Market will be held Sunday, May 4, from 8 am to 3 pm at Republic Lodge No. 1987, 585 Broadhollow Road (Route 110), Melville LI, NY. Plenty of free parking. General admission is $2 (wives and children under 12 admitted free). Indoor sellers tables are $7 and outdoor space is $5; each includes one admission. Talk-in on 144.61/145.21 and 146.52. For additional information, contact Bill Sullivan N2ETG, (516)-689-9871, evenings.

GRAND JUNCTION CO
MAY 10

The Grand Mesa Repeater Society will hold the Seventh Annual Western Slope Amateur Radio and Computer Swapfest on Saturday, May 10, 1986, from 9:00 am to 4:00 pm at the National Guard Armory, 482-28 Road, Grand Junction CO. Admission is free and swap tables are $5.00 each. Features will include an indoor swapfest, amateur radio exams, a packet radio demonstration, an auction, and refreshments. Talk-in on 146.82 and 449.20. To reserve a swap table and for further information, send an SASE to Larry S. Brooks WB0ECV, 3185 Bunting Ave., Grand Junction CO 81504, or call (303)-434-5603.

ROCHESTER NY
MAY 16–18

The Rochester Hamfest and Atlantic Division ARRL Convention, sponsored by the Rochester Amateur Radio Association, Inc., will be held May 16, 17, and 18 at the Monroe Country Fairgrounds, Rochester NY. Tickets are $5 in advance, $7 at the gate. There will be an outdoor flea market, $5 per space. Special indoor flea market for non-commercial exhibitors, upon application in advance only, $75. For tickets, write Hamfest Tickets, 174 Croydon Road, Rochester NY 14610. For more information, write Rochester Hamfest, 300 White Spruce Blvd., Rochester NY 14623, or phone the Hamfest BBS at (716)-424-7136. Talk-in on 146.28/.88. Please note: If you plan on staying at a motel within 40 miles of Rochester, reservations are a must!

RANDOLPH OH
MAY 18

The Portage Amateur Radio Club, Inc., will hold the 1986 Portage Hamfair for radio amateurs and computer hobbyists on Sunday, May 18. It is open for dealers beginning at 6 am and for the public at 7:30 am at the Randolph Fairgrounds, Randolph OH. This fairgrounds facility will accommodate indoor dealer sales as well as an outdoor flea market. Indoor/outdoor spaces can be purchased for either $2 for each 10-foot linear space (no table or chair) or $6 with 8-foot table and chair. Advance reservation recommended; otherwise tables will be available at the door on a first-come-first-served basis. Admission is $3 in advance, $3.50 at the gate. Talk-in on 144.79/145.39. For info or tickets, write Robert Ducotey KX8V, 9971 Diagonal Road, Mantau OH 44255 or call Garry Delagach KD8JM at (216)-274-8240.

KNOXVILLE IL
MAY 18

The Knox County Amateur Radio Club, Inc., 4th Annual Hamfest will be held on May 18, at the Knox County fairgrounds (exit 51 off Interstate 74). Camping area available. Flea market. Large commercial vendor building. Gate opens at 7 am, Commercial Building at 9 am. Donations $4 at gate or $3 in advance to Stuart Schrodt, RR2, LS 19, Avon IL 61415; (309)-465-3107.

DURHAM NC
MAY 24

The Durham FM Association will hold its annual Hamfest and Computerfest on Saturday, May 24, at the lower level of South Square Mall in Durham NC from 8 am to 4 pm. The flea market will be held under a covered parking deck. Talk-in will be on 147.825/.225. Free parking, numerous prizes, and tables will be available. FCC exams are planned. Admission will be $4 at gate. For further information, contact D.F.M.A., PO Box 8651, Durham NC 27707, or call Mick W4ZUS at (919)-544-3556.

TRACY QUE
MAY 25

The Quebec Provincial Hamfest will be held Sunday, May 25, beginning at 9 am (8 am for exhibitors) at the Tracy Curling Club, Place du Centre Civic, Tracy, Quebec Province, Canada. Indoor tables are $8 (includes one admission); outdoor tables are $6—reserve all tables before May 20. Admission is $4. Talk-in, VE2RBS 146.610/.010. Write C.R.A. Sorel-Tracy, C.P. 533, Sorel, Quebec, Canada J3P 5N6.

BEAVERTON OR
JUN 6–8

The 6th annual SEA-PAC Convention (formerly Oregon State) will be held from 5 pm Friday, June 6, to about 2 pm, Sunday, June 8 (open for setups at 10 am Friday), at the Seaside Convention Center, Seaside, OR. Booth space is 8 ft. x 10 ft. with table, chairs, power, and so on for $120; 24-hour security is provided. For motel information, call (800)-452-6740 (from Oregon only) or (503)-738-6391; for other information, write OTVARC, PO Box 5132, Beaverton OR 97006 or call, evenings only, (503)-640-5456 or (503)-297-1175.

WILLOW SPRINGS IL
JUN 8

The Six Meter Club of Chicago, Inc., announces its 29th annual Hamfest, to be held Sunday, June 8, 1986, at Santa Fe Park, 91st and Wolf Road, Willow Springs IL (southwest of downtown Chicago). Reservations for space in the pavillion will be accepted on a first come, first served basis. A donation of $20 in cash per table space is requested. For details, write John Trepina K9QYT, 5015 W. 31st Place, Cicero IL 60650.

RAILROAD DAYS
JUN 21–22

The Great Plains ARC will hold a special-event station June 21 and 22 in conjunction with Railroad Days in Oelwein IA. The bands used will be 20m at 14.235 ± QRM, 40m at 7.235 ± QRM, and 80m at 3.970 ± QRM. The call used will be KC0CP. For certificate, send SASE and QSL to KC0CP, Box 203, Oelwein IA 50662.

GERMANTOWN MD
JUL 27

In celebration of the 40th anniversary of Montgomery College, Montgomery County MD, the Germantown Campus Amateur Radio Club will operate KV3S on Sunday, July 27, 1986, from 1300Z to 2000Z. Frequencies: 7.240 and 14.240 (approximate). A certificate will be awarded to all. Special certificates will be awarded to those whose birth year is 1946 and to those who work KV3S on the 40-meter band. For certificate, send QSL and large SASE to KV3S, Montgomery College, Germantown MD 20874.

ESCANABA MI
AUG 2

The 38th annual Upper Peninsula Hamfest, sponsored by the Delta County Amateur Radio Society (DCARS), will be held August 2, at Bay de Noc Community College in Escanaba MI. This is an ARRL-sanctioned Hamfest and the only one to take place in the upper peninsula of Michigan. Registration will be $2. Donations from organizations to be used for door prizes and awards would be greatly appreciated. All donations will be displayed with the donor's name prominently shown. Donations should be sent to Hamfest Co-chairman Tom Elegeert K8MJK, 1403 S. 13th St., Escanaba MI 49829. For further information, contact Co-chairman Aileen Gagnon WA8DHB, 9159 Bay Shore Drive, Gladstone MI 49837.

NEVER SAY DIE

from page 11

Some just make a noise—others call the police by telephone, others use radio.

Now if you really want to get into it in a very big way, how about putting together some alarm kits and selling them by mail order? I saw plenty of car alarms at the Consumer Electronic Show in Las Vegas in January, but little in home alarm kits. If I wasn't busy with a lot of other things I'd do it myself. Just what I need—one more business. I'd tell you about all the businesses I'm in now, but you wouldn't believe me.

One of my areas of expertise is in making lots of money. I not only have done it, I also give talks on the subject. There are a million millionaires in the United States, so it's no big deal anymore. Almost anyone who really wants to can make a million. I counted ten hams who stopped me at CES to thank me for goading them in my *73* editorials into starting their own businesses and getting rich.

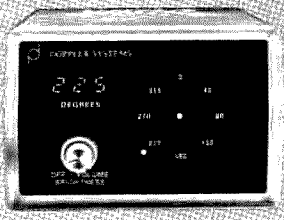
I don't know if you've noticed 8mm video yet. Well, I bought a Sony 8mm camera and VCR and I want to tell you that from what I can see 8mm is going to quickly wipe out Beta and then, eventually VHS. We're going to be seeing low-cost, high-quality video cameras all over the place. Mark my words, you're going to see 8mm video used by virtually every business and in most homes. If you want to get in on the next consumer electronic explosion, see what you can do making some 8mm video accessories or opening 8mm video stores. 8mm video is darned close to ¾-inch video in quality—and a lot better than the ½-inch Beta and VHS formats. The cameras are small and light. The 8mm tape cassettes are about the size of an audio cassette.

For a while the computer business was an easy way to make money. That's slowed down now, but there are other industries coming along. Let me know if you want me to write more about the opportunities. I'll have to swear you to secrecy—we don't want any non-hams getting in on a good thing, do we?

READER'S SERVICE CARDS

I don't know why the previous publisher of *73* dropped the reader service cards—but they're back. The cards are there for you to use to get more information on products you're interested in buying. Buying ham gear is a lot of fun. I don't know of much more exciting than opening up a ham rig carton and setting up a new rig.

Please remember that it's the advertisers who make *73* possible—so treat them kindly. They get all excited when they think you're interested in their products, so give them a shot of adrenaline by circling their number on the card. From there on it's up to how good they are at sending you a sales pitch on their product. If they do a good solid job of selling, who can resist? If they don't send you literature that is almost impossible to resist, send it on to me with your comments. Maybe they need some help.



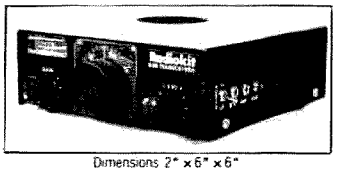
Whatever you do, don't be casual about the reader's service card. Tear it out and use it.

Yes, I know all about how much you hate cards bound into magazines. I hate 'em even more than you do. I read maybe 300 magazines a month, so my bedroom floor is ankle deep in blow-in and bind-in cards I rip out so I can turn the pages. Let me know if you are interested in starting a collection. So why all the cards in magazines? Because the foolish things work, that's why. Why did you think?

I fought the idea for a long time. Then I reluctantly tested it and found how well they worked compared to a coupon printed on a page. No comparison. So I grit my teeth and do what works, whether I personally like it or not. Permission is granted for you to hate the cards—rip 'em out—but then fill 'em in and mail 'em to me—with reader's service and subscriptions.

DIRECTION FINDING?

★ Interference Location
★ Stuck Microphones
★ Cable TV Leaks
★ Security Monitoring



★ VHF and UHF Coverage
★ Computer Interface
★ Speech Synthesizer
★ 12 VDC Operation

New Technology (patent pending) converts any VHF or UHF FM receiver into an advanced Doppler shift radio direction finder. Simply plug into receiver's antenna and external speaker jacks. Uses four omnidirectional antennas. Low noise, high sensitivity for weak signal detection. Call or write for full details and prices.

COMPACT 75 M SSB TRANSCEIVER

Dimensions 2" × 6" × 6"

Complete Kit
$199.95
plus $3.00 shipping and handling

1985-86 CATALOG 50¢

RECEIVER:

Frequency	3.8-4.0 MHz
Sensitivity	0.5 μV for 10 dB S/N
Selectivity	−6 dB @ 2.4 KHz
AGC Range	+60 dB in = +3 dB out
Audio Ouput	>350 mW into 8 ohms

TRANSMITTER:

Frequency	3.8-4.0 MHz
Output	30 watts into 50 ohms
IMD	−30 dB
Harmonics	2nd −47 dB, 3rd −55 dB
SWR Immunity	30:1 @ all phase angles

ALC Amplified, fast response rate (quasi-processing)

POWER REQUIREMENTS:

Voltage	28 Vdc regulated
Current	2A transmit, 65 mA receive

THEY LAUGHED WHEN I SAT DOWN TO BUILD . . .

How would you like to get involved with building some interesting ham projects? Even if you've never pointed to a soldering iron in anger—good grief, there I go dating myself again. Soldering iron, forsooth! Okay, okay, soldering pencil.

While it isn't prudent to tackle building your own synthesized sideband transceiver these days, it's about the only way you're going to get many small gadgets that will be fun to have around your shack. And I have a sneaky plan to bribe you to design and build simple projects.

If you tune around 75m some evenings and listen to the old-timer round-table discussion grousing about how hams don't build anymore, you may tend to believe these fogies. Balderdash! As I've mentioned before, in the early days of ham radio every ham had to build his own receiver and transmitter. Then, when Hallicrafters came out with their first ham receiver (was it the S-1 Skyrider?) hams immediately stopped building receivers.

We all built our own transmitters until well after WWII. It wasn't until then that we had enough hams to make the commercial building of ham transmitters profitable. Amateur radio really got going after 1945, growing a steady 11 percent a year for 17 years—a nice market for commercially made ham rigs.

The few hams who built their own transmitters discovered that this was stupid. The cost of the parts ate them up—and then, when they wanted a new rig they found no sale at any price for a used home-made rig.

One of the reasons I started *73* magazine in 1960 was to publish as many simple construction projects as I could to encourage hams to keep building. I published mountains of articles on building ham gadgets, test equipment, antennas, audio stuff, electronic toys and so on. It worked.

73 was the pioneer in getting hams to build VHF and UHF gear—in getting hams to build solid-state equipment—and then digital, even getting the readers into computers.

No matter how much commercial ham gear we have available, there is still an almost unlimited number of interesting things that we can have only if we build them. Now, 25 years later, *73* is again going to get ham building going in a big way. As I said, I have a sneaky plan.

KIT SUPPLIER WANTED

First, I'm looking for a "Chosen Instrument" company, one that will work with me to make parts kits available for the articles published in *73*.

I'm sure it has not entirely escaped your notice that parts are darned hard to find these days. It's enough to discourage most of us after one or two attempts. It's not like it is in Japan where there is a whole section of Tokyo that specializes in selling electronics parts. There are hundreds of small parts stores—all swarming with thousands of happy Japanese youngsters buying parts. The best we seem to have these days is the slim selection of overpriced parts from Radio Shack stores.

It isn't that there are no parts being made; it's just that you have to buy them in bulk these days—as a manufacturer. The 1963 Incentive Licensing disaster not only put 90 percent of the ham stores in America out of business, it also killed the distribution of electronic parts.

In 1964 I tried to solve this problem by setting up a Parts Kit division of *73*. I bought a huge metal knife to cut out the chassis and panels, a metal brake to bend them, a metal punch set to make the needed large holes and a drill press for the small holes. I bought parts by the zillions from Evans Radio in Concord NH, and sold thousands of boxes of parts for the *73* construction projects.

The parts kits business went well. Oh, a few ham dealers got mad at me for "taking business away from them." But it did encourage thousands of readers to build. The bad aspect was that it kept me incredibly busy. In addition to the kits, I was running a small printing press putting out a monthly VHF magazine, a club newsletter, and an ATV magazine. Then, when my divorce hit, I lost my steam and had to cut back—which included stopping the kits and the small magazines. I even had to get someone else to run *73* for a couple of years.

There's a nice living to be made in the kit business—not a big one, unless we get a spurt of new hams. If some firm is interested, *73* will work with it to coordinate kits and articles.

A ROYALTY TO YOU

Having parts kits is a waste of time unless we have articles on projects you want to build. What I have in mind here is some good old-fashioned bribery. Greed usually works just fine as a motivator. So here it is . . . if you make a gadget that you think *73* readers may be interested in duplicating, write it up, take some pictures, and submit an article. If we accept it, we'll pay you for the article upon acceptance—something some other ham magazines I could name don't do. Secondly, we'll work with the kit people to have a kit made up to support your project. You may want to work with the kit people to simplify or standardize parts. For instance, it isn't very helpful to specify some part you can pick up only at the Dayton flea market. Then, we'll see that the kit company charges enough for the kit so there's a 10 percent royalty in it for you.

Let's say you make up an RTTY demodulator that sells in kit form for $150. You get a $15 royalty on each sale. So, if only a thousand readers buy the kit, you'll get $15,000 bonus for your efforts. Heck, that could be a trip to Europe for you and the XYL, plus maybe a fur coat. You can do a great Asian tour for $6000 for the two of you. But then, you probably won't need expert advice on how to spend the rising tide of money your building efforts can provide. If you find yourself desperate for spending advice, I'll put you in touch with my XYL, a world-class expert.

I'll bet you have something in mind to build right now.

***HR* NOMINATED FOR PRIZE**

HR magazine set a new record in my mind when they reported in their February issue that I was back running *73* magazine. They quoted correctly that I view amateur radio as a dying hobby—and quoted *in*correctly that I've ever said I no longer had any serious interest in it. You won't find anyone anywhere who's ever heard me say that—even on a bad day.

So, with *HR* reaching a new high—only 50 percent wrong—I think they should be given positive encouragement to shake their old "Half Right" nickname. Alas, it seems to have been an impossible goal for them so far, but who knows?

MIAMI HAMBOREE '86

With our hobby coming apart at the seams, how are institutions such as the Hamvention and the Miami Hamboree doing? Even though I wasn't invited to come, I decided to check the Hamboree out.

The Hamboree committee really went out of their way to make things convenient for exhibitors—coffee and doughnuts in the morning and nice lunches delivered to the booths. Dayton, take note!

It's a bit of a shock to get on the plane in Boston with the February temperature well below freezing and emerge in Miami with temperatures in the 80s. I flew down on beleagured Eastern Airlines, using my "Get Up and Go" senior citizen's pass.

The pilot enthusiastically explained all about the brand new Boeing plane he was so proud to be flying—one of the reasons, as I recall, why Eastern is in so much financial trouble. The new plane looked like a worn out junker to me. My tray table was already broken on one side. The toilet light didn't work. The lock on a storage cabinet in the toilet wouldn't close, so the door disconcertingly kept swinging open. This is a new plane? What'll it be like in a few months? It was workmanship like this that drove so many car buyers to foreign cars. Shape up, Boeing.

The Hamboree was in a new location this year—the Tamiami Fairgrounds. I think they've found a good spot. Well, a pretty good spot. There was no air conditioning, so even with a bunch of huge fans blowing, it got pretty hot, badly overloading current underarm deodorant technology.

As an exhibitor I was pleased with the number of attendees. With the help of *73* staffers Nancy Ciampa and Hope Currier, the *73* booth easily kept up with the traffic. I haven't seen the official counts, but I'd estimate they had at least two thousand hams and their families milling around. It never was really crowded, but there were few times when no one was in sight either.

As a show-goer I enjoyed having a chance to see and push buttons on the latest in ham technology. There were two huge flea-market halls, so even if it had rained, I still could have browsed dryly. It poured the day before the hamfest, so the potential was there, making the indoor sales area important.

I was a bit disappointed to see a few non-ham exhibits: Mary Kay cosmetics had a booth. And East-

ern Airlines. Boo. Eastern, I still remember that you were one of the first airlines to ban laptop computers, without any evidence they were a problem. My editorial in *Microcomputing* magazine forced them to rescind that ban.

The best part for me was the stream of hams stopping by the *73* booth to congratulate me on taking over the magazine again. If there were any Wayne Green haters at the Hamboree, they never came near the booth. I was surprised at the number of no-code enthusiasts who admitted they'd been opposed to the no-code license idea until they better understood what really was at stake. They said they now regretted having written the FCC with their first emotional reaction.

I suspect it's too late now as far as no-code is concerned, but I'll spend some time one of these months explaining the whole situation in depth so you can, in turn, explain it to your more volatile, but possibly not very thoughtful, friends. I tend to forget now and then after 35 years of being a ham editor and publisher that I have a different perspective on ham history than hams who are either new or who haven't paid a lot of attention down through the years.

You see, I not only know all the players today, I've known them, both good and bad, ever since I started editing ham magazines—and this August will be my 35th anniversary of that. Yep, in 1951 I'd just gotten a job as a TV director at WXEL in Cleveland, Ohio. I'd been deeply involved with ham Teletype for a couple of years and was frustrated that no one was publishing a RTTY newsletter. Lo, there was a mimeo machine! A few days later the first issue of a RTTY newsletter was born—and my publishing career inadvertently started.

One of the advantages, or disadvantages, of knowing everyone in the ham industry personally, which is what happens when you're a magazine editor, is that you know what is really going on as opposed to what most hams *think* is going on—the facade presented in *QST*.

NEW DEVELOPMENTS

There are a lot of new developments in amateur radio that I've got to get you interested in—like packet radio, repeater cross-banding, and so on. Many of you may be trapped in the past, spending your declining years talking with the same crowd every night. I'm going to try and get you to try something new and exciting.

The one topic that came up the most at Miami was the need for youngsters in the hobby. I've been griping about that for how many years now? As usual, sigh, I guess I was ahead of my time. The ham manufacturers had a meeting and that was number one, two, and three on their agenda.

Sure, I can just hear the senile old farts bitching now—the manufacturers want more hams so they can make more money. You bet they do! But that isn't all. Few hams are in the ham business today just to make money—there are far too many ways to make money easier—a whole lot easier. Most of them are in the business because they love hamming. I wish I could say *all*, but I did see a couple well-known slime-ball crooks exhibiting at the Hamboree, crooks who've cheated hams for years and are still at it. I hear Dayton isn't going to let these bastards exhibit this year. I sure hope not. I've been terribly dismayed to see their ads in one of the ham magazines. I guarantee you won't see 'em in *73*.

Speaking of rip-offs, I just got word that an old-time rip-off artist died. Nice old chap made a living selling high-powered CB amplifiers and expensive mini-antennas that didn't work worth a hoot. I refused to carry his ads, but one of the other ham magazines helped hundreds—maybe thousands—of hams get fleeced.

Some of the biggest crooks in the hobby used to run their ads in *QST*—did for years—despite zillions of complaints. I can remember two who were convicted, one with with my help. I doubt if that can happen today. I don't think Dave Sumner would let it.

Getting back to kids. I've got some ideas on ways for us to get our hobby growing again. My goal is simple: one percent of our population should be hams. Yep, I'm looking for us to get to two and a half million hams. Heh, and you thought 20 meters was crowded right now! Well, don't jump to conclusions. The fact is, I believe we won't find our bands much more crowded than they are today. We'll have enough clout to have more bands and we'll have the enthusiastic youngsters we need to pioneer new modes and new bands.

You know, not one cry of alarm I've been hearing for years about the invasions of CBers has ever been anything more than emotional baloney from our lunatic fringe Chicken Littles. Every time we have a really serious bad apple in our hobby, it's turned out to be an old-time ham with an IQ in the home-temperature-comfort range.

Speaking of CB, it's perhaps with some perversity that I rub old timer noses in the fact that the worst CB bad language and jamming cases in history had Extra Class hams licenses.

CB didn't do much good for us, really. Oh, we got a few hams out of it, but most CBers never got much interested in hamming—and if they did, they found it much easier to move higher in the 27 MHz band than to try and learn the code. The sun-spot cycle, not the FCC, gradually killed this bunch off.

Continued on page 98

WIN $500!

How long have you been a ham? Okay, in all that time, how many really funny ham stories have you read? I've been publishing ham magazines for 35 years and there are precious few I can remember in all that time.

Larson E. Rapp use to get some chuckles a generation ago in *QST*. Say, who wrote those pieces? I think I heard one time, but I've forgotten. Scratchi did pretty well in *CQ* when I was editing it, also a generation ago. I've forgotten who did Scratchi now, too, but I'll bet some reader knows—same W2 who edited the *GE Ham News* around 1947—look through your collection and let me know.

I didn't realize what a closely guarded secret Scratchi's name was until I'd invited the *GE Ham News* editor over to talk to the club. During dinner before the meeting he mentioned that he'd just made a deal with *CQ* to start writing the Scratchi column again. It's one which had previously appeared in *Radio* magazine, which faded away when WWII started. *Radio* was a wonderful magazine—beat the heck out of *QST* in every way. The ARRL never really got over the death of it's founder, Hiram Percy Maxim—also known as The Old Man (TOM). When he suddenly died around 1936 there was a fight for power which I hope will someday be documented. Maxim wrote several wonderfully humorous books—his "A Genius in the Family" was a best seller in the 30s.

Getting back to ham humor, long, long ago in *73* I had a wonderful piece by Jean Shepherd K2ORS. Jeans' promised to do more, but hasn't gotten around to it yet. I hope you've seen his movies on PBS—vintage Shepherd and very nicely done. Sherry's taped Jean's Christmas movie from one of the cable channels. I hope Jean'll do some more work for us to add to ham humor posterity before he becomes a silent key.

The best humor I've seen in any ham magazine was by Bob Manning K1LSD. I'll start reprinting some of his *73* stories from twenty years ago so you can see what I mean.

Another ham with a great sense of humor, but who rarely let it go in print, was Sam Harris W1FZJ. He did a piece for me in *CQ* which is still a classic on his Contest 100 Watt Final. When things get dull I pull that off the shelf and read it to visiting hams.

What I'm leading up to is this. With the exception of Shep, none of these hams were professional writers or humorists. I'm sure there are dozens of you who, if you gave it a try, could entertain us. Here's where the $500 prize comes in. I'm offering $500 for the best ham humor story submitted during 1986—as voted by the *73* readers.

Let's see what you can do. You couldn't ask for better source material than ham radio for humor. Please double space your manuscript. You get extra points if you do it on a word processor—there are even some people still writing longhand, despite the popularity and speed of the typewriter. A word processor makes writing even faster and much easier.

Please send your piece to Ham Humor, *73* Magazine, WGE Center, Peterborough NH 03458 USA. The sooner the better.—W2NSD/1.

NEVER SAY DIE

from page 94

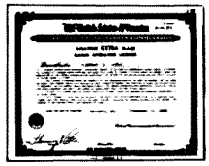
A PUBLISHER'S WORK IS NEVER DONE

One thing—please do everything you can not to get upset if I don't answer you personally. I doubt if you know anyone who is as busy as me, so let's keep it with me writing editorials, you writing letters—and yes, I *do* read 'em. If you either are clever enough to make me laugh, or are so wound up about something as to actually be serious, there's a chance your letter, or at least embarrassing parts of it, may get published.

I'm not exaggerating about being busy. In addition to getting to hamfests, I also get to computer and consumer electronic shows—including a round of 'em in Asia in October. I also get out for some skiing in the winter and scuba diving in the summer, Honduras last August.

I'm also doing my best, which isn't all that good at times, to run a few businesses—like trying to get *73* magazine growing again in circulation and advertising. I sure need your help with this. Then there's my *Digital Audio* magazine, the *Green CD Catalog*, *Pico* and *Tele* magazines, five Instant Software computer stores and a mail order house around greater Boston, WGE Distributing, WGE International (importing), Green Publishing Institute, and a few smaller projects.

To these you add a number of new projects being started—magazines, new products and services—and perhaps you can appreciate why I don't have much time to answer letters.



There are a few civic duties too, such as being a director of IDG, the largest computer publishing firm in the world, an overseer for RPI, a member of the N.H. High Tech Council and the FCC's Long Range Planning Committee, things like that. I don't have many boring days.

If you're interested, I'll tell you more about some of my upcoming projects. Who knows, you might want to invest in one or two. I seem to be able to make a lot of money, and I haven't much use for it for myself.

I was very pleased by the many hams who stopped by the booth to say they're getting *Digital Audio* magazine and enjoying it. You might mention it to your compact disc fanatic friends.

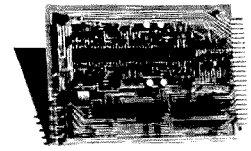
I want to thank everyone who said hello at Miami and wished me luck with getting *73* to be more interesting. It'll take a while, but just watch.

THE TRADITION CONTINUES . . .

NOW AVAILABLE AGAIN!

THE FCC DISCONTINUED ITS CLASSIC "FORM 659" LICENSE CERTIFICATE, LEAVING ONLY WALLET-SIZED TICKETS AVAILABLE TO AMATEURS.

NOW YOU CAN AGAIN HAVE THE TOUCH OF CLASS THAT HAS ADORNED STATION WALLS FOR DECADES.



FIVE FINELY-PRINTED CERTIFICATES (NOVICE, TECHNICIAN, GENERAL, ADVANCED, AND AMATEUR EXTRA CLASS) ARE AVAILABLE.

EACH DISPLAYS LICENSE CLASS, NAME OF OPERATOR, CALL-SIGN AND ISSUE DATE OF FCC LICENSE.

PLEASE SEND A COPY OF YOUR FCC LICENSE OR UPGRADE CERTIFICATE WITH CHECK OR M.O. FOR $8 TO:

OC-1 ONLY $59.95

Complete with Shipping/Handling USA

OC-2 ONLY $79.95

ON CALL is a complete selective call system so you don't have to monitor the frequency, or it can be used as a decoder for controlling equipment at the repeater site and at home.

Compare these features:

- 4 digit 16 tone sequential decorder programmable, 43,680 different codes, DTMF* Format with Auto reset
- 1 AMP SPST relay output, momentary or latched for external paging device, such as Auto horn, tape recorder, speaker Audio etc.
- Flashing LED call indicator. (Energizes when your code has been accessed)
- easy connection to any radio
- 12-16 volt DC operation
- Size: OC-1 - 3.1 x 2.15 x .5 in.
  OC-2 - 2.3 x 3.75 x .875 in.
- can be used for clubs or emergency groups for help situations

73 INTERNATIONAL

Just because I started this column as a result of visiting DX hams is no reason you shouldn't put in your 2¢ worth and let me know what DX news you find most interesting. My inclination is to have DX ops tell us what they think is interesting—how we can get permission to operate if we're fortunate enough to visit—any coming DXpeditions—what's doing with repeaters—things like that. What do YOU find most interesting? Since we have a world hobby, I think you'll be as interested as I in what is going on. If nothing else, it gives us something to talk about on the air which, from what I'm hearing these days, can't hurt.

—Wayne.

VK5—JAW'S HOME TERRITORY

Jaws, or The Great White Pointer Shark, has a reputation in most parts of the world for being a large fish, but in VK5, around Port Lincoln, world fishing records involving sharks have been broken time after time. There have been skeletal remains of the Great White Shark in this area recorded as being up to 60 feet long, and some fishermen swear that they are still around at near this length.

There is, nearly every year, some sort of White Pointer attack in these waters. Keep the above in mind as you read the following from Carol VK5PWA, the current president of LEPARC, giving a rundown on their Club Activities for this and next year. They offer an open invitation to call in on your way to the America's Cup, and will welcome with open arms any Americans, especially those from Orange, Texas, their sister state.

They are holding a Hamfest from October 11–13, with all the usual activities, with an added bonus of a trip at the end, for those interested, WX permitting, to the Dangerous Reef, the home of the world's White Pointers.

LEPARC—by VK5PWA

The Lower Eyre Peninsula ARC was formed in late 1978 and over the past years has grown to a membership of 25. Our early meetings were held in members' homes, but with the formation of the local State Emergency Service (SES), we were able to use a room in their building.

We helped them erect towers for joint use and we obtained our first lot of equipment with the help of the local Lions Club. However, within a few years the SES operation became much bigger than expected and we were asked to find alternative accommodations. Our local Council offered us the use of land adjacent to the SES compound and offered us a loan of $1,000 to help us establish our facility. We were fortunate in obtaining a caboose for our radio shack, and two disused guard vans for our workshop and storeroom.

We also acquired a 20 by 24 shed—donated, provided that we move it from its site! In March, '85 the concrete slab for the floor was laid, and Easter Monday found all hands on deck to stand our "new" building up. This structure has now been lined and the ceiling has been installed, together with an overwhelming number of power points. This room was unofficially opened with a flagon of port and paper cups at our June Meeting.

During late 1984 it was decided that as a club we should consider a special project for 1985, the joint celebrations of the WIA and International Youth Year. After discussion with some interested students, their schools were asked if they would like to have amateur radio as an elective choice for 1985. Naturally, we were almost killed in the rush, but we decided to limit the groups to 10 per class. The end result was two groups of year-10 students at Port Lincoln High, and one group of year-9 students at St. Joseph's Convent.

Term 1 was pretty solid—video tapes, lectures, and on-air sessions during the 11-week course. Term 2 has been workshop sessions, recognizing, testing and sorting components. They have also started on a construction project in two parts:

Part 1. A two-valve reaction radio receiver suitable for listening to broadcast and SW bands up to 30 MHz.

Part 2. Novice valve transmitter—CW+AM—to be assembled as a supplement of Part 1.

A prototype to receive 80- and 40-meter bands has been constructed and, although lacking in agc, was able to resolve all signals heard on an FRG7 receiver for those bands. Students will also take part in the forthcoming contests as 2nd Ops.

Term 3 will be more theory and, after the exams in November, the high spot of the year will be an expedition to Boston Island, a nearby offshore island. Equipment to be used will include the rigs built by the students and an early model rig built by Alf Treager (the father of outback pedal radio). Other equipment will also be used to fill out band coverage and thus ensure plenty of contacts.

The venue and dates still have to be confirmed as we are experiencing quite a number of problems. These are not new to anyone who has tried to organize a similar venture.

We have the support of the South Australian branch of the WIA and we have applied to the Department of Communications

Amateur Radio Live Across The Nullarbor—September 12, 1985. The Goldfields Amateur Radio Group (Kalgoorlie, Western Australia) welcomes V15JSA Railway Mobile. From the left, VK5AQZ (project coordinator), SWL 60370, VK5ZN, VK6ZGQ, and XYL Susan, VK6ZX and XYL VK6KYL, and (hidden) VK6ZAJ. Photos by VK5BPA.

Amateur Radio Live Across The Nullarbor—September 15, 1985. Graham Horlin-Smith VK5AQZ hopped out of his berth when the bands opened. (See the March, 1986, issue of 73, Australia column, for the story.)

for a special callsign, VI5IYY (International Youth Year). Between bouts with all this radio activity, the students are trying to come up with a suitable QSL card and T-shirt design. The Commonwealth Bank of Australia will sponsor the QSL cards.

So, listen out over the next few months—you may hear some of our prospective hams calling: "CQ, CQ, CO—VK5ALE VK5ALE VK5ALE—Second Opp Calling."

The Club has a Kenwood TS-520 rig, a 2m rig—and our RTTY machine is almost on air. Signals received do not have enough audio to be resolved on our Seimens Machine; we're busy doing a few adjustments, so it's really close to being "on-air."

We also have a bit of homebrew gear, including the ATU in fulltime use at the club. Antenna system includes Slim Jim and beam for 2m and a trapped dipole for other frequencies. We are working on a hat to load one of our towers as a vertical on the low frequencies.

Further club activities include a weekly club net on 3.560 (plus or minus QRM) at 0830 UTC on Fridays, plus a slow Morse session for VK5 division of the WIA on Monday nights.

If you are interested in a stopover or want further information, please write to LEPARC, PO Box 937, Port Lincoln, Australia 5606.

Kirsti Jenkins-Smith VK9NL
PO Box 90
Norfolk Island
Australia 2899

NORFOLK ISLAND

We knew we were playing for time back in 1976 when the powers that be decided to install an FM transmitter in the Norfolk Island broadcasting station.

"You won't need AM," they said. "This is a big step forward, keeping up with modern technology," it was maintained. Naturally, the people who made all the decisions (and still do) know little or nothing about SWL eager beavers and other interested persons straining to hear the elusive signals from VL2NI.

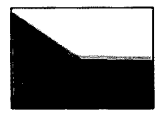
Some time during the second half of November, 1985, time ran out for AM broadcasting on Norfolk Island. The AM transmitter had ceased to function. The authorities did try to do something. They telephoned Papua New Guinea to talk with Jim VK9NS/P29JS to see if there was anything he could lend them in the way of equipment.

Personally, I do not think an amateur rig suitable for prolonged broadcasting, but then I am not a technical person. In any case, there was nothing Jim could do in the circumstances, and in a QSO with VK9ND on Norfolk Island, I learned that it had been decided to forego AM broadcasting from now on. So there we are. If you can't hear them on FM, you can't hear them at all.

Another leap up and away was the Aussat satellite which is now in place. So now there is only a dish standing between regular television and hardly any TV. Because it was possible to receive TV even before Aussat.

Jim and I used the six-metre beam for antenna, and during the summer months, TV pictures would come in in a ghostly sort of way: pictures fading in and out with two or three different stations intermingling. This interplay between stations could at times be quite hilarious. Best remembered is the voices of politicians seriously discussing a news item. The picture, however, showed muppets sitting around a table discussing something else. The scene was perfectly synchronized. The words of the politicians matched the movements of the muppet mouths to a tick!

Best TV program I have seen for years. It is doubtful if the satellite will provide good entertainment like that.



Amateur radio activity from Norfolk Island declined in November with a further 25 percent (myself) leaving the Island temporarily, the weather until then had been good for sitting inside playing with the radio. It rained almost every day from February onwards. And it blew.

The storm moved the beam so that the headings were all wrong. Not being crazy about climbing towers, I made up new headings on a piece of cardboard. The beam was roughly 135 degrees out. Africa? Where had Africa got to these days? Ah! There it was, up where the U.S.A. used to be. The U.S.A. had moved down to the Antarctic.

I was just beginning to get used to the new headings when a new storm moved the beam back to 45 degrees out. New headings. New confusion. I think Welikovski must have had a finger in the pie.

What with poor propagation and crooked paths in 1985, it hardly mattered. With so little activity and no AM broadcast, Norfolk has nearly slipped back into the dark ages, when few people knew of its existence. However, it does exist, Brigadoon-like. Sunning itself in cool temperate breezes out there in the Pacific.

The year 1986 should bring new awakening. Jim will be home to climb the tower. So we should emerge from the dumps of the sunspot cycle with Norfolk Island geared to communicate with the outside world once again.

Czechoslovakia

UHF

During the contest "SNERA" that has been organized together with the magazine *Radio* and the Department of Communication of the USSR, the competing stations registered seven days in the course of July, 1984. During these days, polar glow with radio effects occurred. In August, 1984, there were eight and in September, 1984, as many as 14 days. UA9AAZ was listening to the station SM4GVF in the 145-MHz band at the distance of 2300 kilometers and RA3AGS was listening to the station PA and GM in the 433-MHz band.

RS I

(Radio Soviet ORBIT) According to the assertion of UA4FP, telemetry of the beacon RS1 in the frequency of 29.401 MHz can be heard from time to time. The directing centre in Moscow tries to also put the converter into operation but for the time being it was not successful.

SHORT WAVES

Every month in Czechoslovakia there has been organized a state contest in the band of 160m. The contest is organized for the increase of an operator skill under the title "Test 160." It is devoted mainly to young operators OK/OL. It lasts one hour by operating CW. In February, 1985 the first three places were occupied by these stations:OK1DWA—2,604 points, OK3CZM—2,552 points, and OL1BIP—1,825 points.

DXCC STANDINGS

The best stations in Czechoslovakia to March 10, 1985 (first figure, DXCC land confirmed, second, old DXCC): Mix (CW + Phone): OK3MM—315/355, OK1ADM—315/346, and OK1MP—314/345; CW: OK3JW—298/302, OK1TA—295/301, and OK3EY—295/299; Phone: OK1ADM—314/340, OK1MP—313/339, and OK1TA—310/325.

The champion of Czechoslovakia of collective stations on UHF for the year 1984, in which the results of the biggest European races on UHF are being included, became the radio club OK1KRG from Prague with 131 points; next were OK1KIR with 110 points and OK1KRA with 100 points, also from Prague, evidence their exemplary devotion to work on UHF.

RTTY

OK1VXO–OK1VVM have put into practice RTTY by using the micro computer ZX-81. The circuit of the contact between the computer, reception converter and generator AFSK is fit with the circuit MHB 1012, MH3205, MH7400, NE555. The program was worked out by Jirko OK1VXO.

From OK1JT I received further information on his experiment with the ZX-81. He uses the teletypewriter RFT only for the recording of the received relations. He assures the transmission by means of the micro computer and the program. For the interconnection of the computer, teletypewriter, tape reader and converter with generator AFSK, OK1JT uses the circuit of the contact according to OK2BFS. The operation program in the language Basic, that was elaborated by OK1JT, assures automatic transmission of calls, various texts from memory prepared in advance, printing of QSL sent by air, and, of course, transmission of the texts from the digit key strip ZX-81. OK1JT had no problems with mutual interference of the transmitter and the computer.

Annually the honoring of the best Czech and Moravian radio amateurs takes place. Late in January, 1985, the best radio amateurs meet in Tisnov to receive the prizes for their many years of service. The evaluation was done on the basis of the vote of the members of the Czechoslovak Central Council of radio amateurs.

The first place was occupied by a twofold world champion in radio

orientation races and a master of sports, Eng. Mojmir Sukenik with 270 points Pavel Sir OK1AIY received 183 points for his work on UHF and in third place was Eng. Karel Karmasin OK2FD for his work on short waves, with 166 points.

CONTESTS

In the VK/XL RTTY DX Contest, 1984, three Czechoslovak radio clubs achieved perfect placements in the category of collective stations, with multi-operator. They occupied the first three places in the world in this sequence: OK3KJF–110.000 points, followed by OK3RJB and OK3KXJ.

Besides that, listener OK2-21478 won the first place in the world of SWLs.

RTTY

Station OK1DRX not only improved its program for RTTY by means of a ZX-Spectrum computer, but by means of this computer made contact in the 145-MHz band with OK1VAT.

AMSAT OSCAR 10

Since the end of April till the beginning of October, 1984, Jenda OK2EH, by operating CW, made 150 contacts with 56 lands according to the DXCC list. He has been using electronic equipment of a multiplier type with electron tube REE3OB. The receiver is MWEc with a converter and the antennas are 12-element yagi for the reception and a 15-element yagi (or a spiral antenna with 10 threads) for the transmission. Both of them are revolving in both levels.

Radio club OK1KRA wrote that they had been working with the following Czechoslovak stations: OK1AIY, OK1KHI /p, OK1DIG, OK1KTL/p, OK1DKS, OK1DTL, OK2AQK, OK3AU and OK3RMW. Station OK1KRA is the first station from Czechoslovakia and the first one of the socialist states that had been working with 57 DXCC lands.

Some remarks made by OK1VPZ:

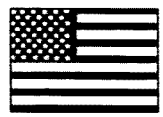
(1) It is necessary to listen perfectly, the antenna, 16-element yagi F9FT, or 2 by 9-element yagi F9FT crossed for circular polarization, with a preamplifier.

(2) Since there is an output of 20 Watts in the MHz, we have exactly the same as we need.

(3) As for the mentioned antennas, it is necessary to have exact prediction of the position of the satellite. It is best from the computer.

(4) If the signal of the computer is not strong enough, we call only weak stations, because if they have weak signals, they hear themselves and also us.

Over one and a half years, Ondrej OK3AU made in mode B about 2,500 contacts with 67 DXCC lands. Besides that, he had been working occasionally under callsigns OK5MIR, OK5KWA, and OK0WCY. Ondrej confirmed a sad reality—that unnecessary overloading of the converter in mode B has not been changing for the better. On the contrary, the number of stations using enormous erp outputs to the radar values in spite of improving their receiver system, has increased.



Vlasta OK2VPA from Opava has been also working through AO-10/B where he has made 100 contacts. She appreciates most the contact with the station VS6XLA from Hong Kong.

SATELLITES RS

At present, during the period of the quiet sun, there are good conditions for the work via satellites RS. At the beginning of 1985, OK3AU, OK3FH, and OK3ZFA were working regularly on them. Also stations from Bohemia and Moravia, OK1DJW, OK1BMW, and OK2AQK appeared. From time to time some unique stations with special prefixes EU, EO, EW, EV, station UA0KAJ from Kamchatka and the stations JW from Svalbard can be heard.

Michal OK2BXF from Brno made contacts with 28 DXCC lands through satellites RS. He made some contacts with erp-5 Watts (RS5). He heard himself back with 15 Watt erp, by means of today already outdated satellite RS6.

According to unofficial information, new satellites RS9 and RS10 have been successfully tested in Kaluga near Moscow. The satellites are equipped with two converters, 145/29 MHz and 21/29 MHz.

GUAM

Edward L. Campbell KB6DAW/KH2
300a Rendova
APO San Francisco CA 96334

I thought I would write a little about the Island in this column, with a little on the lifestyles and some history.

Guam is a small island, 30 miles long by 12 miles wide—about 225,000 acres. It has a population of about 175,000 with 20,000 being transient with the military.

Guam is know as the hub of the Pacific. It is a major link to satellite communications in the Pacific with a NASA tracking station. Guam is 6,000 miles from Los Angeles, 3,644 miles from Honolulu, 3,500 miles from Singapore, 3,000 miles from Manila, and 1,550 from Tokyo.

Guam has two types of seasons, wet and dry, the wet season being from July to December. Guam's average temperature is 86 at its high with its low being about 75. The yearly rainfall is about 85 inches. During the rainy season, Guam is lush and green.

The highest point on Guam is Mt. Lamlam (1336 feet), in northern Guam, with undisturbed jungle.

At the north end is Andersen Air Force Base, and at the southern end is Apra Harbour and the main Naval Station. Speaking of the southern end, there is a small island known as Cocos Island. It is about 2.8 square miles and is a large tourist attraction with a hotel and sandy beaches. It also has a small zoo with tropical birds and other wildlife.

Guam is part of an underwater mountain chain that includes Japan.

The people of Guam are a mixture of Chinese, Japanese, Koreans, Filipinos, Micronesians, and of Spanish descent, and also us statesiders. The Guamanian people are know as Chamorros (the women are Chamorritas).

Guam, after many years of rule by the Spanish, became a US Territory, after the Spanish American War and the Treaty of Paris, 1898. In 1950, the Chomorro people were given their citizenship by Congress. In 1971, Guam elected its first delegate to the US Congress.

Guam is a duty-free place for tourists, with some of the prices being 50% lower than stateside prices.

There are about 100 hams on Guam, with many not active. Sixty are in the Marianas Amateur Radio Club (MARC) of which I am the secretary.

To finish up, the island is a laid-back type of place with lots of water sports, good prices for the shopper, and pretty decent propagation for the DXer. So if you get the chance, come by and see us.

Here are a few lines on my trip to Wake Island and thanks to those who helped: P29JS for the vertical and headset donated by the HIDXA and the 220 net; AH9AC, who helped me plan and coordinate plane schedules and the use of some of the equipment; WH9AAD, a Novice on the island who was in charge of the "motel" there, who made sure that I had a room to myself; the communications officer who allowed me to use the facilities; of course the Base Commander, Maj. Westmoreland, who gave me permission to visit there and who might try to help me with the next trip next year; NK6T for the use of his rig during the CQ WW while he was off to Japan, and KC6RM for his help putting up the vertical for the lower bands—and his technical work on the rigs to keep me up on the air.

My call has been changed from KB6DAW/KH2 or KH9 to AH2BE, which will be AH2BE/KH9. That will make things a little easier since it is shorter.

Now all in all, I made 6,200 QSOs. 122 countries, all the states, and all but 4 zones. So not too bad with only 7 days on the air. The first two days were getting the rigs and antennas up and on the air, so that the following days would be nothing but air time. I did not have an external vfo so a lot of the 40-meter split work was by running back and forth from 7.085 to 7.195 on one vfo. It was slow but it worked.

Mostly I used an FT-101b that I borrowed from KC6RM; I finished up with a TS-830S. The 830 had some receive problems—that is why I used the other rigs. Gary NY6M was supposed to go, but he made a stripe and his officer had other orders for him, so he could not go. I had to go by myself. Next time I will make provisions for that and have two people in line to go with me. If Gary had been along, we would not have left so early and could have doubled the number of contacts made. But all in all, the trip was a success.

Propagation was excellent to all areas except Europe. I hope the next trip will be more fruitful for them. I am also planning to do a two-band-a-day-only schedule so that each band will get as much time as possible. And also hoping to get up on the top band so that 160 will get some attention.

Anyway, I got on the island on the 23rd, their time. After about an

hour I was on the air. My first contact was HC8E. Not a bad way to get started! Then checked in to the 220 net. It was open long path to Europe at that time, and had problems staying on the net because of the QRM.

After the net I went to the 7.085 net with Eric ZL3AAG, but the band was very noisy—as was 75 meters. In the Pacific, the lower bands are very noisy as a whole. My best two bands were 20 and 40, though. As the days progressed I did also the QSOs. I was always in a pileup which made it hard to call some of the stations that I needed. My country list would have been greater otherwise.

I left on the 31st of October on a plane on its way directly to Guam. My voice was gone. I was getting only five hours of sleep a day. (Except after the contest, then I slept 18 hours.) I worked all but four hours of it. AH9AC did that part for me.

Now I did have some fun. I had a four-day stopover on KH6 and worked a few people on 2 meters. I did not know there were so many repeaters in such a small place HI HI HI. . .

Also while I was enroute, there were some interesting things happening. It just so happens that the same month was the 50th anniversaries for Amateur Radio and the first China Clipper flights from the states to the Far East. So lots of celebrations on the island. So for amateur radio it was a small milestone.

For those I made contact with, I hope you have sent for your cards for this event. If you haven't, please do so as soon as possible. I will be packing my bags to go to HL9-land soon and I want to make sure that you get yours. And an SASE would be appreciated. It makes things go faster.

I have a small trip to 8P6-land planned while I am there visiting my inlaws. My father-in-law is 8P6JQ. I will be as active as possible from there. I hope to have an 8P9 call. You will find me on the PHO net or the 220 net with P29JS—or should I say VK9NS?

I am trying with the help of HL9TW or HL9CW to have my HL9 call before I leave Guam so that I can get out the word in advance. I hope to get HL9MM. And am still planning to return to KH9 next year.

As of this writing, almost three years as a ham, I have contacted over 230 countries with 195 confirmed. And I hope those I have sent cards to will return them to me as soon as possible so I can put them in for my DXCC.

SPACELAB-D1 MISSION

In November, 1985, space shuttle Challenger carrying the German Spacelab-D1 mission landed again. But even today one cannot fully assess all the outcomes of this mission for the amateur-radio community.

Astronauts were Reinhard Furrer DD6CF, Ernst Messerschmidt DG2KM, and Wubbo Ockels PE1LFO. Here are some of Messerschmidt's comments. Regarding his amateur-radio activity in space, Ernst said: "I think I made only a quarter hundred QSOs because of the immense program of work we had to do. The transceiver was just sitting there and I had a chance to hit the button when only I passed by. However, I enjoyed it very much that every time I turned the radio on someone was calling us. Even over the Pacific. I asked someone from the space shuttle crew whether he would see any land or island—but no. Probably the call came from a ship out there."

Regarding the pileups, Ernst commented: "Of course, the pileups were roughly proportional to the amateur radio population of the area we just flew over."

A demonstration of what he was talking about was a tape recording which was incomprehensible sometimes due to the European QRM. But some minutes later, it reproduced the only voice of a station calling from South Africa, and nothing else. A total of 12 hours of tape recording was brought back.

Unfortunately, the astronauts did not manage to get in contact with DP0GVN, the German amateur radio station of the Georg-von-Neumayer base in the Antarctic. The station was operated by Lothar Baumann DG5SL, at that time—who can be heard regularly via OSCAR 10 and who tried hard to catch the Spacelab station. Better luck next time!

Ernst's comment on the importance of amateur radio in space: "Every time I heard the voices calling us I had the good feeling that we were still in contact with someone on the ground. I consider amateur radio a great leisure activity, in particular for the personnel manning the first space station in about 10–12 years from now. Another aspect is to think about amateur radio activity from an orbiting space vehicle via geostationary satellites. That could keep us in contact with all continents permanently and would enhance our chances to set up schedules which fit better into our program of work."

The amateur radio activity aboard Spacelab-D1 received particular good attention in the media here in Germany. There were dozens of newspapers reporting from their local amateur radio station on the tracking, calling and receiving at least the beacon of the spacelab amateur radio station. The subject was also very well covered in a 45-minute TV report with truly professional recordings and film clips of the astronauts talking from Spacelab via amateur radio and of their counterparts on the ground.

Besides the many positive experiences, there were the ever-recurring problems of handling large pileups and the nuisance of stations chatting on the transmission frequency of the astronauts. A thorough analysis of the state of the art of working through conventional DX pileups and an attempt to derive procedures applicable to space communication may be worthwhile. Furthermore, the multi-channel, fixed frequency, and separate transmit/receive features of space communication may lead to completely different and perhaps more advanced solutions of this problem. Bright ideas are badly needed, in particular in the light of the Spacelab-D2 mission coming up in 1988.

"Bright ideas will always get our support, in a way we helped amateur radio to become operational on Spacelab-D1," said Heinz Riesenhuber, secretary of the German Department of Research and Technology.

All right, it's up to us again.

HAM AT THE HELM

Prime Minister Rajiv Gandhi VU2RG has been in power for just over a year, having succeeded his mother, Indira Gandhi, on 1st November 1984. This period has seen an extensive change in the policies of the government which have even won the grudging appreciation of the opposition. Quite a few of these are of interest to hams.

While he was a member of Parliament in 1984, Rajiv was responsible for the waiver of customs duty on amateur equipment, with a limit of Rs. 10,000 (roughly US $1,000) which was expected to cover all but the most sophisticated transceiver. The waiver was valid till December 31, 1985. Prices have been going up along with sophistication, and there are many pieces of equipment that ten thousand rupees cannot buy any more. Responding to representations by the Federation of Amateur Radio Societies of India (FARSI) and others, government has now extended the validity of the waiver till the end of 1986, and has enhanced the limit to Rs. 15,000, making it possible to bring in any equipment that one might fancy.

The Indian electronics industry had enjoyed a sheltered market dominated by the favored few who had been given industrial licenses to make electronic products. One fine day, the Prime Minister made a statement in Parliament, indicating imminent relaxation of these restrictions. What followed was a wholesale liberation of the industry from its shackles. The electronics industry has not yet responded to this move with any tangible results—reduced prices or better products. The Prime Minister recently warned the industry to take heed that Government will go to any extent to see that the benefits of liberalization reach the common man.

Rajiv Gandhi has also swerved from his mother's policies about the computer industry. At one time, Indians returning from tours abroad could sneak in computers only by making customs officers believe that they were video games or electronic typewriters. Today, one can bring in a personal computer valued up to US$300 without hassles, by paying the appropriate duty on it. The Indian computer industry (where the Sinclair/Timex ZX81 with 1K RAM once sold for over US$500) has also benefited by reduction of import duty and liberal import of components and peripherals. Almost anyone who proposes to make personal computer or microprocessor-based systems is given a license to go ahead. It is the Prime Minister's wish that computers should become as common in Indian schools and households as they are abroad.

Government has also recognized that young engineers bubbling with enthusiasm can produce dramatic results. To illustrate this concept, a centre for Development of Telematics, C-DOT for short, was recently formed with a few hundred fresh graduate engineers under the leadership of a couple of US-returned Indian engineers, charged with the development of an electronic telephone exchange. This group has, within a year, produced an excellent electronic PBX and is forging ahead towards its ultimate goal. It is likely that more such goal-oriented young-engineer projects, including amateur-radio and personal-computer hardware, will be promoted either by the Government or with its blessings, thanks to VU2RG.

JAPAN INC.—THE INDIAN COUNTERPART

A reader in the "Feedback" section of *Radio*, India's only amateur radio journal, has written "I would be happy if you include an article on how to import a rig from abroad on our own as the dealers of Japanese companies in India keep a good profit. So just to prevent their monopoly and help the hams of India, it is a must for every ham to know how to import the rigs. Some of the ham friends outside India can give us their rigs or arrange the rigs on a no profit, no loss basis.

This statement might sound rather harsh, but there is quite some justification for the reader to feel bad.

Ever since import of amateur equipment was freed from import control in 1980, local representatives of Japanese manufacturers have created an impression that used equipment is not permitted to be imported under Open General License (OGL). Five years and several clarifications later, these agents continue to din into the ears of prospective purchasers that they are not permitted to import used equipment.

Most amateurs who did not want to take chances, fell for this canard and refrained from importing used equipment, just to avoid the hassles that the doomsayers assured them were bound to bog down their rigs at the customs.

Concerned with the small number of persons who were on the air even after import restrictions were relaxed, Government went one further and fully waived import duty. The agents went into business again spreading the word that those importing used equipment will not be eligible either to duty waiver or free imports.

Not satisfied with the 20 to 25 percent commission that they get from the manufacturers, they add "handling charges," cable charges, and incidental expenses adding up to at least a further 10 percent of the cost of the rig. The fast appreciation of the Yen also gives

DEALER DIRECTORY

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, land-mobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

G=Good, F=Fair, P=Poor.

Look for some disturbances in magnetic field between 5th and 10th with possible storm levels; also possible 6- and 2-meter openings in this period. Again, between the 27th and 30th look for active magnetic field conditions and generally poor propagation on HF, LF, and VHF.

them the opportunity to ask for some more in the name of currency fluctuations. Airfreight adds US$120 on a Yaesu FT-757GX, the most popular import in India.

A number of amateurs ask why the Japanese manufacturers will not ship by other modes. The agents say their principals will not change their policy. Take it or leave it! And they help the swing towards "take" by adding that the duty waiver will not be extended.

It has been extended thrice, and the new deadline is December 31, 1986, with reasonable chances of further extension.

What recourse does the poor Indian ham have? It has to be conceded that amateur radio has today become an appliance operation the world over. India is no exception. If amateur radio is to keep growing, appliances have to be made available *without* the added cost of Japan Inc.'s local arm.

Short of switching his allegiance to the only US-made transceiver which has fewer knobs and features than the Japanese stuff, Mr. Indian Ham has to live with the problem and educate himself on the intricacies of the import control and customer laws and procedures. To what extent this can be accomplished remains to be seen.

LIBERIA

Brother Donald Steffes, C.S.C.
EL2AL/WB8HFY
Box 716
Notre Dame IN 46556

Ninety three and a half inches of rain in five weeks! That was the recorded rainfall in Monrovia that was reported on The West African Net early last September. Until then it had been a very *dry*, wet season! The accumulation was running more than 20 inches below the lowest records of the past four years!

The antennas were well washed but communication was bad. Even 40 meters (which is our "workhorse" band for calling up and down Liberia) sometimes goes almost to zero. DX communication was worse and we expatriots were feeling very lonesome as we talked to the stratosphere and got no answers.

In the meantime, the repeaters were working. In an earlier column I wrote about our plan to link the Monrovia and the Bong Mines repeaters. They are linked and we have HT communication from both ends. We have never had it so good.

Now Mark Munson, M.D. EL5G has come back with another repeater. Plans are under way to install that little one-Watt unit in the Zorzor area which is near the north end of Liberia and link it with the two repeaters down here. The distance is 90 miles to Bong Mines and 120 to Monrovia. If it is necessary they will use a linear and when everything is working we will give a full report in this column.

Mark is a missionary serving a 120-bed hospital in Zorzor, and once a month he travels another 100 miles to Foya to bring the service of a doctor to the hospital there. When Mark has his new repeater working it will give him regular and easy communication with Monrovia. The radio is his only means of contacting the world outside.

The amateurs in Liberia enjoy a great deal of freedom and the missionaries working in this country use it to great advantage. When they come to begin their tour of duty, the amateur license is high on their list of priorities, and the Liberia Radio Amateur Association does everything that is possible to help them.

In the States there are many nets that are organized and exist for the sole purpose of serving American missionaries or armed service personnel. They do this with great dedication and sacrifice on the part of their members. It seems to me that an article recognizing their contribution and listing the times and frequencies at which they operate would be in order. Such an article would increase an awareness of this work, and in all probability many American amateurs would offer their expertise and join one of these nets. At the same time it would serve as a kind of a directory for those that need the help of these nets.

So long as our amateurs show themselves to be responsible and use the amateur bands in accordance with the law and accepted customs we will continue to enjoy this freedom. Every effort is being made to ensure that this be done and it is a rare instance when a correction has to be made.

Note from the International Editor: Don EL2AL has left Liberia. We will miss the interesting reports he so faithfully sent us. Anyone like to fill his shoes?

HAM HELP

I am in the U.S. Navy stationed in Japan and I'm looking for a good used linear amp, 250 W and up, preferably for 10–80 meters, but I'll consider any HF amp.

NEVER SAY DIE

THE RIGHT TO LISTEN

If it weren't such an obvious sign of our dumb bureaucracy running amok—giving me even less confidence in congress than I already have left—which isn't much—this craziness over listening to the radio would be one heck of a joke.

Take the million or so people who've bought satellite dishes. For several years now they've been rationalizing their listening to signals intended for cable distribution by telling the rest of us that, what the hell, if the industry doesn't like us buying a system and tuning in to their satellite feeds, why don't they encode them? Fine, I bought that concept.

Now (hold your chair for this one) the satellite dish owners are up in arms, bringing suit against the cable people, trying to force them *not* to encode their transmissions. What kind of nut cases do we have out there? And I certainly don't put down the lawyers who've clustered to fight for this incredibly stupid premise—they're the only ones who can't lose.

Which brings me to the telephone, that revered instrument of confidentiality—the instrument the cellular crowd is trying to make safe for democracy. What a bunch of guano. Firstly, if you know anyone who works for The Phone Company, just ask them about telephone privacy. There *is* no such thing. I've had many telephone people tell me for years that The Phone Company has always made it a practice of listening in randomly to phone calls. Sure, all these people could be lying—and so could the underground telephone newsletters which say the same thing.

Okay, let's say that TPC absolutely doesn't do any such horrid thing. Next in line, unless you've been completely tied up jamming 40-meter service nets for the last few years, is the fact that much of the telephone traffic is sent over microwave links. You also are well aware that Russia has oddly enough set up listening points near many of these links. They have the technology to not just listen in to almost any phone call they want, they could easily record everything and have a computer sort through zillions of calls looking for specific numbers or key words.

How many years have we been using cordless phones? Several. Well, I suppose there are some people who are so dense that they don't realize that every word they say can be heard for a considerable distance by anyone with even the slightest interest—or the willingness to waste his time listening.

So now comes cellular radio and, surprise of surprises, anguish that radio signals aren't private. Gee, who would have ever thought someone could buy a radio and tune in to radio signals? Let's make it illegal to make radios. No, I guess we've got to let 'em make 'em, but maybe we can make it illegal to buy them. How about making it illegal to use them? Sure!

So here we go again, right into a legislative mess far beyond anything the simple congressmen involved ever imagined. Okay now, we've got to prevent people from listening to cordless phones—that means we've got to stop people with broadcast radios from tuning the high end. Perhaps we can make it obligatory that every broadcast radio have a miniature alarm transmitter which would trigger automatically when the dial is turned to the high end, alert-

"We're glad you're interested in the apartment! There's one small problem, though . . . a 100-foot tower in the back yard!"

Packet Reprieve

THIRD-PARTY TRAFFIC sent via packet radio is legal, at least for the time being. Last month we reported that the Federal Communications Commission had nixed using auto-forwarding systems to transmit third-party traffic. The FCC, in effect deciding that the medium by which a message is sent is not important, stated that a control operator must be present every time a third-party message is passed. The FCC has granted an ARRL Petition for Extraordinary Relief which will allow store-and-forward automatic message handling to continue until a final decision on the matter is made later this summer. Specifically, the waiver allows automatic transmission of third-party traffic using AX.25 (or compatible) protocol on frequencies above 50 MHz. Also, the FCC warns, "Control operators. . . capable of monitoring AX.25 packet transmissions must be alert to the increased dependency upon them for monitoring during the period of this waiver. We call upon them to immediately make known to the responsible control operator of a station retransmitting communications under automatic control any misuse of the station so that the control operator can take prompt corrective action." The FCC will be watching us closely. Our behavior during this waiver will undoubtedly be considered when the commissioners make a final decision on automatic third-party packet systems.

Big Hit

THIS MONTH'S discussion on the **National Teleconference Radio Net** will focus on lightning and power surges. Ed Bellamy and Bill Paulin of Lightning Elimination Associates will host the program. Charlie Kosman WB2NQV will also speak on the upcoming "Hands Across America" project in which six million people will form a living chain stretching from coast to coast. Charlie says that 4,300 hams are needed to coordinate security and safety teams. The NTRN will start at 8 p.m. CDST on May 1, 1986—contact your local repeater guru to find out which machine in your area will be connected.

Harry D. Hooton

***73*'s GOOD FRIEND** and longtime antenna expert,W6TYH, passed away on Christmas Day, at the age of 74. Harry loved antennas and authored numerous articles for *73*. He also wrote the *Single Sideband Book*. In a typical Hooton *73* spectacular, Harry lightheartedly described how he brought down a stubborn wire antenna with a couple of blasts from a 12-gauge shotgun, much to the delight of the crowd of neighborhood children gathered to "help." Despite his poor health in the last few years, Harry continued to "round up the kids" to test antenna designs; when the antennas worked, he sent us the plans. (If they didn't, ka-boom.) In the true ham tradition, Harry's antennas were always a complicated system of pulleys, buckets of sand, and miles of wire set up at precise angles. I'm sure he factored in tree growth, too. We at *73* knew Harry only through his work, but his articles didn't hide his humor and his kind nature. He wrote several of his last articles for us while bedridden, and it is only as his key falls silent that we realize how much we'll miss Harry Hooton.

CIA Maps

IF YOU'RE NOT SATISFIED with what the State Deparment has to say about a country, why not try the CIA? **Phil Spotts** offers a series of color "intelligence" maps which point out geographic features, industries, crops, land utilization, population density, rail lines, roads, airports, and seaports for the nations of the world. The maps are $10 apiece—get in touch with Phil at Best Press Services, PO Box 27073, Phoenix AZ 85061. Send an SASE for a list of available maps.

RFI Update

FROM CANADA come more details on the trial and tribulation of **Jack Ravenscroft VE3SR.** Last year Jack was sued by his neighbors, Tim and Dale Houghtby, who claimed that Jack's amateur radio interfered with their electronic organ and their microwave oven. The Canadian DOC examined Ravenscroft's station and pronounced it "clean." In court, the plaintiffs produced a tape of the interference caused to their organ—and were surprised to learn that the CW had come from VE3OAI, a ham living about 500 feet away from the Houghtbys. Also, the microwave oven that turned on and off of its own accord was fixed when defective components were replaced. Ravenscroft's defense centered around the fact that consumer electronic equipment is simply not immune to rf interference.

Branching Out

FOR YEARS hams have talked about using trees as antennas, and some experiments have shown promising results. Now a West German radiation expert reports that rf can adversely affect trees; he claims that radio waves can decimate forests. The researcher says that leaves, needles, and branches are stressed as they act as mini-antennas, and the stress kills the tree. The foliage also confuses microwave radiation with sunlight, causing the tree to think that the middle of a winter night is the height of a summer day.

TNC Fix

IF YOU OWN a **TAPR TNC-2** or an **AEA PK-80,** listen up. Both of these models use resistor R98 (4.7k Ohms) to provide a software-readable input from the modem. SIO IC U22 provides a pulsed output on the same pin that R98 is connected to; there is a chance that the state machine's operation will be interfered with. To fix this, just replace R98 with a 100k-Ohm resistor.

ACTS Axed

AMSAT'S HOPED-FOR ride into geosynchronous orbit aboard NASA's ACTS satellite is a no-go. It looked as if room aboard the new bird could be made for an OSCAR Phase IV system, but ACTS Program Manager Dan Brandel vetoed the plan because the AMSAT transponder might not be compatible with the ACTS satellite.

Big Bear Base

LOOK FOR KDØDJ/HR3 in Honduras through June. The station, located at base camp Big Bear, near Yoro, is manned by **Chief Warrant Officer Jim Roberson** and **CWO Don Hayes.** The two are on a road-building training exercise, Operation General Terencio Sierra-86, and are attached to the Missouri Army Nation-

CWO Jim Roberson operating KDØDJ/HR3 near Yoro, Honduras.

al Guard. Jim is a UH-1 helicopter pilot with the 135th Engineer Support Group and Don is the Task Force Maintenance Officer for the 203rd Engineer Battalion. The station is operated a few hours per day, mainly for stateside phone patches, on 15, 20, and 75 meters.

Out the Hatch

THE SOVIET UNION has replaced the aged Salyut-7 space station with a new, larger one called Mir (Peace). After an automatic shakedown of the orbiter, the first cosmonauts to occupy the new platform were sent up in a rare, nationally-televised launch. It is very likely that the cosmonauts will manually launch **ISKRA 4**, a small amateur satellite with an uplink and downlink in the HF bands. "Manual launch" means that the satellite will be dumped out through Mir's garbage disposal system. ISKRA 4 will have a low, circular orbit that will rapidly decay. Mir is in an eccentric orbit, 307 by 185 km, and you should be able to see the space station as it orbits the earth. A side note: There have been reports of voice communications from Mir on 143.625 MHz.

F2A Okay

A TEN-METER REPEATER can legally identify itself using F2A, thanks to a recent amendment to section 97.61a of the amateur rules. The FCC also changed other sections of Part 97 to indicate F2A authorization wherever F3E repeaters are allowed. The commission had apparently forgotten to include the mode when new emission charts were drawn up. (If you don't know what all those numbers and letters mean, send for *73*'s Genuine FCC Emission Clarification List—it's free for an SASE sent to *73* Magazine, WGE Center, Peterborough NH 03458. Attn: Emissions.)

No Way, Lee

LEE SHOBLOM K6ADA has been denied his request to use portions of the amateur 440-MHz band for news-gathering. Shoblom had asked that he be allowed to use amateur frequencies and equipment to send ATV pictures from remote locations back to his studio, citing the high cost of commercial gear. The FCC agreed with the ARRL and others that the proposal was contrary to the principles of ham radio.

Gun Jumping

WISHFUL THINKING DEPARTMENT: I jumped the gun last month, reporting that two new Soviet satellites, RS-9 and RS-10, had been successfully launched. The mysterious telemetry on ten meters, thought to be coming from the new birds, has been positively identified as emanating from RS-1. RS-1, which has been useless for amateur communication for several years, occasionally pops to life briefly when its batteries charge up. The two new satellites are still undergoing ground tests and are expected to be launched later this year.

Royal Ham

CONGRATULATIONS to His Majesty King Hussein JY1 of Jordan and Her Majesty Queen Noor JY2NH on the birth of their fourth child, **Her Royal Highness Princess Raya JY2RBH.** Speaking of birthdays, 56 Jordanian hams worked nearly 56,000 stations during an on-the-air celebration in honor of HM King Hussein's 50th. Mohammed Ali Nugrush JY4YJ cranked out around 800 QSOs a day for a total log of 11,600 stations, and was awarded a giant silver trophy for his effort by His Highness Prince Raad Bin Zeid JY2RZ.

UK on Six

NOW THAT SIX METERS is available in the United Kingdom, activity is mushrooming there on 50 MHz. The *RSGB News Bulletin* reports plenty of stations to work, most of them running CW. Other countries with new six-meter privileges include Ireland, where 20 special permits have been issued to Class-A license holders (including EI2W, EI9D, and EI6AS), and Portugal, where CT1WW has a 50-MHz permit and is running 3 Watts.

Beacon Bulletin

A NEW TWO-METER BEACON is now operational in Iceland. TF8VHF is on 144.939 MHz, running 40 Watts to a six-element yagi up about 50 feet. The antenna is pointed roughly east.

World Notes

JIM SACKEY N9ESM sent us an interesting package describing "Background Notes," a publication of the U.S. Department of State. Each Note is a summary of information about a single country, such as geography, government, and economy. A map of the country is also included. About 170 Notes are availble at $1 each ($42 for the entire set), or you may subscribe to the series for $32 per year. (The Notes are updated every two years, and a one-year subscription includes around 60 Notes.) Jim points out that "Background Notes" are a good way to learn more about the countries we contact on the air. You can get more information about this publication by calling the Government Printing Office at (202)-783-3238.

Hamfest Help

CHRIS SULESKE N4LZG writes with help for the weary hamfester who wears his faithful HT on his belt. Concerning the rubber duck antenna: "First, connect two BNC ninety-degree angle adapters together. Attach the male end of this combination to the HT. Attach the female end to the antenna; you now have a pivot which angles the antenna downward over the side of the HT. I find this useful in keeping the duckie out of my armpit." Thanks, Chris.

Bar None

THE BIG WINNER in *73*'s Name That Bar Contest ("Fun!," April, 1986) is **Pete Louzader N1CTV.** Pete sent us not one, not two, but *three* separate Western Union Mailgrams, plus electronic mail via CompuServe! In the first Mailgram, the winning entry, Pete describes the bar and its environs: "The 73 Bar and Restaraunt is located at 73 New Street in the Wall Street area of New York City. New Street runs from Wall Street south to Beaver Street...the street is narrow... about 18 feet curb-to-curb. The sandwich shop [next door] is The Sandwich Genie at 69 New Street. Also in this area are the Drago Shoe Repair Shop, the Silver Stars Deli, and the Beaver Key and Lock Shop." Pete is the Director of Facilities Engineering for Automatic Data Processing, Inc., and wins a one-year subscription to *73* for his sharp eye and dry throat.

NK6K > Packet

A NEW PACKET-RADIO COLUMN premiers in this issue of *73* on page 86. "NK6K > Packet," conducted by **Harold Price NK6K,** will explore current trends in packet radio and serve as a national sounding board for the packet community. Harold's name and call will be familiar to packeteers: He has been a major player in the development of amateur packet radio. In fact, Harold participated in the very first on-the-air contact using AX.25 protocol. He also is one-third of the team which wrote the software for TAPR's TNC-1. Welcome to *73*, Harold!

Read Heard

HEARD ISLAND ODYSSEY, a new book by "*73* International" correspondent Kirsti Jenkins-Smith VK9NL, is now available in the United States. The book chronicles the adventures of the Heard Island DXpedition led by Jim Smith VK9NS. Copies are $12.25 (Ohio residents add 6% sales tax). Contact Ron Pretekin AB8K, 6741 Oak Field Drive, Dayton OH 45415.

QSP

"QRX" comes to you this month courtesy of MSgt. Sheldon Daitch WA4MZZ, *The Shortwave Magazine*, *The JY Newsletter*, *Sweden Calling DXers*, *The RaRa Rag*, and *Amateur Radio News*. Send your news and photographs to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: QRX.

NEVER SAY DIE

from page 4

ing our new Radio Police Force to home in and read the perpetrator his or her rights.

But what about those spies who are tuning into microwave telephone relays? Well, they're going to need a dish or other microwave antenna, so let's make everyone register all microwave antennas. It shouldn't take more than a staff of 50,000 and a budget of $1 billion a year to handle that one. Of course that won't stop the spies because they'll have their antennas within their embassy compounds, beyond the reach of our laws and registration.

Now, what about cellular? Same thing. Let's have every radio capable of tuning those frequencies or being modified to tune those frequencies registered. We'll also have to register the sale of parts because it's so easy to build a small downconverter which would let you tune those frequencies on a low-band rig. I think we'll need a little bigger budget for this one—maybe $5 billion will handle it. But heck, that's no more than the cost of an extra shuttle or three toilet seats for Air Force One.

You know, we haven't even begun. What about the low lifes who are tuning in those new telephones in commercial planes? And the millions of marine telephones? Come *on*, congress—a fine mess you've gotten us into!

CALL THE FCC!

Here's a news flash for you: The FCC is sick and tired of being called every time a ham somewhere gets upset over some terrible thing another ham is doing. Hey, is amateur radio supposed to be self-policing or isn't it? Well, the fact is we're supposed to take care of ourselves and not keep pleading for Big Brother to come in and do an A-Team job on your local jammer. . . or whatever.

In case you haven't a good grasp on the FCC's role in our hobby, let's look at the situation. I find, in my talks with clubs, that many amateurs have a weirdly distorted view of the FCC and its relationship with us.

Try thinking of the FCC as a benevolent bureaucracy—one which has our best interests in mind, but which has both hands and one leg tied by a shortage of funds. It hops around on one leg as best it can to help us out, despite its severe limitations.

The FCC has some very large problems with which it's trying to cope. The whole telephone situation has come unglued as a result of the Bell breakup. Thousands of new firms are fiercely fighting to get pieces of this restructuring, with the FCC having to decide for or against their survival at every turn.

Add to that the increasing legal problems with satellite communications such as the thousands of firms selling earth stations to homeowners on the basis that it's legal for anyone to receive TV signals. . . after all, if the cable people want to keep you from receiving their programs they can encode 'em, right? Now the same bunch is trying to sue the cable people to stop them from encoding their programs on the basis of the investment people have in earth stations.

And so it goes. Communications is up by about two orders of magnitude in the last generation, yet the FCC has been forced to cope with this escalating mess with less and less funds. They need some ham bitching about a repeater jammer or an errant CBer like we need a solar flare radio blackout.

Another thing they really look forward to is the continuous dribble of ill-thought-out petitions for rule changes. These things, which we think are of world importance, are so far down on their scale of priorities that I'm sure there are many people at the FCC who wish we'd just shut up and go away.

The FCC budget cuts have virtually eliminated their monitoring functions, so there's really not much they can do to help us put some jerk ham out of business just because he's causing intentional interference. Heck, I doubt if the entire FCC monitoring division, if brought in from all over the country, could make a dent in our L.A. jamming problem.

Okay, if we're living in a dream world when we think we can turn to Big Brother to fight our fights for us, perhaps it is getting time to adjust to reality and come to grips with it. You know as well as I that we don't need the FCC. There isn't one single thing the FCC is doing right now which we can't do better ourselves, once we face up to it. A whole lot better.

The strength of amateur radio, to my mind, lies in the local amateur radio clubs. As the saying goes, in union there is strength. The excesses of American worker unions has tainted the word union—wherever there is power there will be people anxious to abuse it. That's not currently a problem in amateur radio, but it has been in the past and, mark my words, it will be again.

If we want to improve amateur radio, our best course is to strengthen our club structure. The first step then is to get more hams to join ham clubs so we'll have the club strength we need to be self-policing. Next we can aim at being self-determining, but we can't achieve the second until we've managed the first step.

Club Growth

The big secret in making a ham club a success is both simple and complicated. It goes with—and flies against—human nature. The simple part is the basic rule: If you want to have a successful ham club all you have to do is make it fun to be a member. Oddly enough, most people—and that, to a large degree, includes hams—prefer fun to boredom. People love to get together and lie to each other. Perhaps you've noticed the popularity of parties? Yep, if you pattern your ham club meetings after parties, you're going to have so many members you'll have to find a new place to meet.

There are good parties and bummers, so just making a club meeting more like a party isn't necessarily going to do it. The key to a successful party is making sure that everyone has fun. Now I can give you some guidance toward making your ham club meetings fun, but I want you to try 'em. Afterwards get the members to critique the meeting so you can learn what works and what doesn't work—and perhaps even why. Next, write a letter to *73* telling me what you've discovered—what did and what didn't work. I'll get this into *73* so other clubs can learn from your experience. Together we can build ham clubs which will give amateur radio the strength we need to cope with anything.

As you get to thinking in terms of providing fun, you'll begin to notice that very few members give good marks to business meetings. They just aren't fun. We've managed to lose thousands of ham clubs down through the years, victims of long, boring business meetings. Clubs should, as much as possible, have ail club business taken care of by an executive committee. If a member gripes, have him come to the next executive committee meeting—that'll shut him up.

Business meetings are pernicious in that members tend to get deeply involved with them when they're happening, so the club officers may not realize the deadliness of what's happening. The pattern has been repeated over and over—meetings where mem-

Continued on page 76

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, WGE Center, 70 Rte. 202 N., Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

LETTERS

BUBBLE GUM FUN?

Hear! Hear!

NJ8F, writing in the March issue, hit home dead center! With the average age of hams at 46, I wonder what the average age of a *73* subscriber might be? A few years older, I imagine! I join Staff Stafford in his comment/complaint that the type size was too small for many of your gray-power customers.

I would like to offer a comment/complaint of my own. With the average age of a ham at 46 (I am somewhat older) the "Fun!" feature by KI2U hits far short of the mark. It is written, in my opinion, for a much younger, bubble-gum-chewing audience. The space could be used better for presenting some of Wayne's "finger in the dike" ideas for saving ham radio from itself.

All in good cheer!

Mick McDaniel W6FGE
San Diego CA

We went back to 8-point type (from the too-small 6) in the March issue. (Articles are in 9-point type.) As far as "Fun!" is concerned, over 18% of our readers "read it regularly," and more than a thousand responded to the 1985 KI2U poll (see June issue). No bubble gum was found adhering to any of the responses.—KW1O.

PACKET SOAPBOX

I was a little amazed at the letter on packet radio by Mr. Payne (*73*, December, 1985). I must agree with his indignation at the statements indicating that packet radio will replace other forms of RTTY. It is simply an additional mode, although "packet" has been in use by the military for years. It is with the remainder of his letter that I must take umbrage.

I don't know what magazines Mr. Payne reads or what dealers he talks to, but for some time packet node controllers have been available for less than $200. One manufacturer even has a computer-interface model that does CW/RTTY/AMTOR/ASCII *and* packet. As for the baud rate, most ASCII TTY is 110 to 300 baud. (By the way—nothing is "error-free" if conditions are minimal.)

As concerns satellite communications, a simple set of converters at a 15-W output level will put you on the air for less than $200, not counting antennas (build them yourself). As concerns antennas for satellites, admittedly some have large dishes, but the largest I personally know of is 12 feet. Small yagi arrays (11–22 elements) are much more common. Mr. Payne's example of 12 over 12 (mine is 11 x 11, purchased used for $35) yields an estimated 13-dB gain for approximately 200 erp for a 10-W input—the output of most small rigs and converters without needing an amplifier.

Perhaps before making such disparaging statements, Mr. Payne should do some research on his subject first. He might enjoy the hobby more.

Now that I'm off my soapbox, thanks for a great magazine.

Dean Milner VE1CBF
Sydney, Nova Scotia

My first satellite QSO (through RS-7) was made with an Ameco 2m rig, bought at a hamfest for $20, feeding a 5/8-wave magmount attached to a metal ashtray and propped up on the roof. I just used my dipole for the 10m downlink. Has anyone done it cheaper?—KW1O.

SHORT, SWEET, 'N' SOUR

Joined local radio club as SWL after a mall demo. Took two years for club to decide to have Novice class. During class we had 4 out of 9 students drop out. When I asked older club members to give these people help, the answer was, "Let them do it the hard way like I did." After becoming a Novice and getting on air, no advice, help, inspiration, or whatever was put forth, and if I hadn't gotten POed I would have quit. "Army psychology." By constant prodding of my "peers" Novice instructor stayed after club meeting to help us to upgrade. Eleven months from Novice I made General and other 4 made Tech. Now 2 years later; only one other made General. There have been two Novice classes, as I got students and bugged instructor and with offer to help we had classes. I got candidates for classes in supermarket (baggers), donut shop, and by asking fellows if they would like to be hams and explaining. Two classes started with 15 each and ended with 7 and 2, primarily because instructor was boring and taught *Tune In The World*, your basic Pass-A-Test-But-Learn-And-Understand-Nothing. I wanted to start by first making code oscillator and learning the what, why, and how of components. Of course it would take more time, but it's worth it to create hams instead of machine operators—real hams. Some of our last Novice candidates came from the *73*-inspired "Ham-Day," March 24, 1985, where 4 in club of 50 invited in others. I asked everyone: people in local Post Office, man who gave me lift when I ran out of gas, official at election place, and a couple of Boy Scouts. Made contact with hams on Antigua and Newfoundland so they would help out. Got 4 Novices out of it. Been looking for Ham-Day info for 1986 but have been disappointed and this is what prompted all this. *Why no Ham-Day?*

Last Friday at 6th-Grade Science Fair I demo'd hamming. Asked kids from 4th, 5th, and 6th grades their first names and showed them how in CW. After an average of 3 times they could do it pretty well, so I told them to come back in 10 minutes or so and see if they still could do it. Long story short—got nine young Novice candidates out of four hours. Fun. That's how hard code is.

I criticized QSL Bureau and was told how much work. . . . I know a General-class op that can't tune his rig if somebody moves controls around. Know one who went from Novice to Extra in 3 months but can't fix his keyer or even try. Takes tests well, though. What I think is wrong with ham radio is the older hams—most of them are not doing their job! They need inspiration or kick in pants.

Walter G. Bastow N4KVF
Gold Hill NC

OK, there's one vote for another Ham-Day. Any others?—Ed.

HE WHO LAUGHS LAST

Welcome back, Wayne! The magazine has missed and needed you. Hope you are able to bring it back to the old rabble-rousing, controversial, yet interesting ham monthly it once was.

Please consider bringing back some features now gone but that I enjoyed in the past—namely, Pasternack's "Looking West," and "Circuits."

I used to laugh at your editorials when you stated that the masses would be using computers soon. Not me, said I. So here I am, using a Commodore 64 and a Speedscript word processor. OK. You were right at least once!

Frank L. Gore K6RTZ
Sierra Madre CA

Look for our old friend WA6ITF in next month's 73.*—Ed.*

DEAR WAYNE:

Thank God—you're back!

Ben Alabastro WA2PXR
Frankfort NY

WELCOME BACK!

Byron Kretzman W2JTP
Huntington NY

Welcome back! To me, *73 is* Wayne Green. I was sorry to see you leave and am glad to see you back. I won't stop my subscription now!

George Lesch WB2ENP
Staten Island NY

Nice to have you back!

Walter Taylor K2MLT
Hammondsport NY

Thank heaven you are back! Now I'll keep my subscription to *73*.

Merv Simpson WA6YSD
Santa Rosa CA

When you left *73*, so did I—now that you're back, so am I. Wayne, how about giving us the *73* we used to have?

Hal Beebe N6IWI
San Leandro CA

Just watch!—Wayne.

TOOTH & NAIL

Your info about the 40 hams who support K6ADA is totally wrong (*73*, December, 1985, page 7). First off, there aren't 40 hams in the area, and the hams who are in the area will fight tooth

NEW PRODUCTS

FOX TANGO NEWSLETTER INDEX

Fox Tango Corporation now offers a comprehensive cumulative index to the *FT Newsletter* covering 1976–1985. Articles are grouped by model number (FT-101, FT-757, and so on), and called out by year and page, topic, title, and author.

Both the index ($4 ppd. in the U.S. and Canada, $5 elsewhere) and individual volumes are available from *Fox Tango Corporation, Box 15944, West Palm Beach FL 33411; (305)-683-9587.* Reader service number 154.

SAMS ACQUIRES BOOK LINE

Howard W. Sams, Inc., has acquired the Basic Electricity series of books from Texas Instruments. The series consists of three hardbound books, two lab manuals, and an audio course. The three books are *Basic Electricity and Dc Circuits* ($14.95), *Basic Ac Circuits* ($19.95), and *Basic Electronics Technology* ($19.95). The two lab manuals, *Practical Applications of Dc Theory* and *Practical Applications of Ac Theory*, are available for $12 each.

For more information about these and other Sams books, contact *Howard W. Sams and Company, 4300 West 62nd Street, Indianapolis IN 46268; (800)-428-SAMS.* Reader service number 156.

REGENCY MX-5500 SCANNER

Regency Electronics has announced a 25–550-MHz continuous-coverage scanner. The MX-5500 covers all standard VHF and UHF bands, including four amateur bands (6, 2, 1-1/4, and 3/4 meters). The scanner is preprogrammed at the factory with 20 popular frequencies and is capable of searching through a band for active frequencies.

Designed for home or mobile use, the MX-5500 comes with a telescoping whip antenna, an ac power supply, a dc power cord, and a mobile mounting bracket.

For complete details, contact *Regency Electronics, Inc., 7707 Records Street, Indianapolis IN 46226.* Reader service number 155.

DX HOW-TO FROM TAB BOOKS

DX Power: Effective Techniques for Radio Amateurs is a new book co-published by the American Radio Relay League and Tab Books. Author Eugene Tilton K5RSG gives advice and how-to tips on all facets of DX and DXing, including how to bluff successfully, how to work the DXCC list systematically, and how to stalk rare DX. Tilton explains the special techniques used on the various amateur bands and details leapfrogging, tailending, random calling, and other methods to increase your DXCC total.

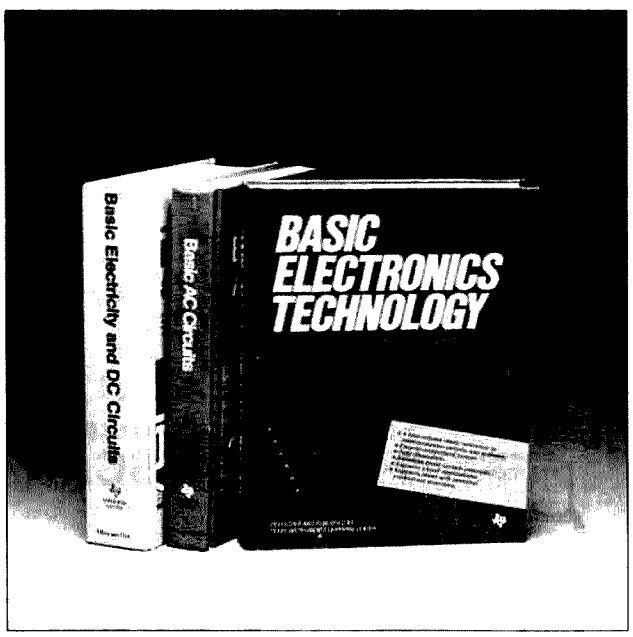
For more information, contact *TAB Books, Inc., Blue Ridge Summit PA 17214; (717)-794-2191.* Reader service number 159.

The Regency MX-5500 25–550 MHz scanner.

ICOM ANNOUNCES IC-751A

ICOM has announced a newly designed update of their IC-751. The IC-751A is a 100-Watt HF transceiver with a .1–30-MHz general-coverage receiver. Features include all-mode, 100% duty cycle operation, 12-volt power supply, an electronic keyer, a 500-Hz CW filter, QSK up to 40 wpm, an LED annunciator, and improved noise blanking.

For more information, contact *ICOM America, Inc., PO Box C-90029, Bellevue WA 98009-9029.*



APA PACKET SWITCH

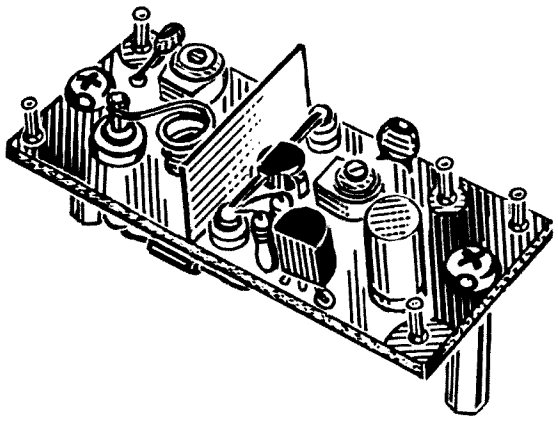
Amateur Packet Alaska has announced the APA VHF/HF Switch, a device which allows any TNC-1 or TNC-2 packet system to be instantly switched from VHF/1200-baud to HF/300-baud operation without retuning or recalibrating. The switch can be activated either manually or by external logic. The switch is housed within the TNC cabinet and takes about an hour to build and install.

The APA VHF/HF Switch is available for $30, and a 15-page nomograph describing VHF/HF switch designs is $3. Please note that APA is an all-volunteer organization and is not equipped to receive telephone or credit card orders. Contact *Amateur Packet Alaska, AX.25 Communications Trail, Ester AK 99725.* Reader service number 160.

WINNER'S EDGE SOFTWARE

Winner's Edge Software has released a new contester's system for the Commodore 64 and 128. Contester II maintains multiplier checklists, dupe sheets, logs, running score, multiplier tallies, and other statistics. The program

Electronics courseware now available from Sams.



ICOM's new IC-751A HF transceiver.

sends CW, including preprogrammed and user-supplied contest exchanges.

Separate modules expand the basic program's functions to cover specific contests; the ARRL DX Contest module is now available, and modules for the ARRL Sweepstakes and the *CQ* Worldwide DX Contest will be available later this year.

The Contester II requires a Commodore 64 or 128 and one disk drive. A printer is optional. The program is available for $39.95 postpaid from *Winner's Edge Software, 2003 Sarazen Place, Reston VA 22091; (703)-620-3776.* Reader service number 161.

Hamtronics' LNW preamp.

Metz offers stainless-stees antenna systems.

HAMTRONICS ADDS LOW-BAND PREAMPS

Hamtronics has added low-band units to their popular line of GaAsFET preamps. Typical gain is 22 to 28 dB with a typical noise figure of .8 dB. The preamps are small enough (1.6" x 0.6") that they may be installed inside most radios; connections are made by soldering subminiature coax directly to terminal pins on the preamp PC board. Models available are: LNW-28 (25–35 MHz), LNW-50 (35–55 MHz), LNW-75 (55–90 MHz), LNW-100 (90–120 MHz), LNW-144 (120–150 MHz), LNW-160 (150–200 MHz), LNW-220 (200–270 MHz), and LNW-432 (400–500 MHz). Each preamp is $19 in kit form or $34 assembled.

A 40-page catalog describing these and other Hamtronics products is available for $1 (overseas send $2) from *Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535; (716)-392-9430.*

METZ STAINLESS-STEEL ANTENNAS

Metz Communication Corporation now offers a complete line of VHF and UHF stainless-steel antennas, hardware, and low-loss RG-8/X coaxial cable. Stainless-steel coils designed for each amateur band from 10 meters to 450 MHz can handle 250 Watts of rf. Each coil is pretested, identified with a serial number, and coded for the band of operation. The antennas mate with SO-239 connectors; magnetic, through-glass, and other mounts are also available from Metz.

For comlete details, contact *Metz Communication Corporation, Corner of Routes 11 and 11C, Laconia NH 03246.* Reader service number 157.

Head-to-head: Uniden's Bearcat 800XLT versus Regency's MX-7000

by Marc Stern N1BLH

Regency Electronics, Inc.
7707 Records Street
Indianapolis IN 46226
MX-7000: $699.95

Uniden-Bearcat
6345 Castleway Ct.
Indianapolis IN 46250
800XLT: $499.95

The Uniden-Bearcat 800XLT.

When you first look at the Regency MX-7000 and the Uniden-Bearcat 800XLT side by side, an automotive analogy comes to mind. The MX-7000 seems like a rocket-fast Ferrari, while the 800XLT is like a Chevy—basic transportation. Looks as if it's a case of old technology up against the latest in microcomputer-based systems.

Even the boxes give this impression: The Bearcat looks like Bearcats have always looked, while the Regency has a sleek, modern shape with a sloping front, an LCD and a tiny box.

But look again—rather than simply being a case of old versus new, it's more a question of why change for the sake of change? The 800XLT uses the same style of box that has served Uniden-Bearcat for years. It's a practical design that was outlined more than 10 years ago when the first programmable Bearcats appeared and that has been refined ever since. On the whole, it's a much more comfortable design to use.

For example, the 800XLT keyboard angles out from the display area in a way that makes the scanner easy to program. Likewise, the gas fluorescent display is easy to read from about 10 feet away. This visibility has as much to do with the type of display and its brightness as with its viewing angle, which is good.

The Regency MX-7000.

The MX-7000's LCD is visible in most lighting conditions because of the angle of the display, but there are times when ambient light can overwhelm it and cause it to wash out. The display light offers little help because it's too small and doesn't illuminate the display area brightly enough.

Awkward Entry

The MX-7000 is loaded with high-tech goodies and capabilities, but you are forced to handle many of the functions yourself—entering bandwidth, for instance—while in the 800XLT much of the work has been handled in software. For example, if you choose to scan frequencies from 118–136 (the aeronautical service band), the 800XLT automatically selects AM rather than FM. With the MX-7000, you must physically select AM and enter it along with the frequency choice and the memory channel choice, which is rather inconvenient.

In fact, the method of memory entry in the MX-7000 is not only awkward, it's dangerous—it's possible to unintentionally overwrite existing memory information. For example, when you're writing memory information to the MX-7000's scratch pad, you must not only enter the type of modulation technique—narrowband or wideband, FM or AM—but also the bandwidth of the signals you'll be monitoring and the frequency. When this is done, the flag "CH" blinks at you on the LCD as the MX-7000 asks you to store the information in one of its 20 memory locations. So far, this seems pretty straightforward, and it is, but unless you are quick on the membrane keyboard, by the time you're ready to enter this information, you may well have forgotten the channel in which you are storing the information, and you may easily overwrite an existing entry.

This type of mistake is also possible with the 800XLT, but it's a lot less likely to occur because fewer steps are needed to program in a frequency. Again taking the aero band as an example, to program in a frequency you simply manually advance the memory display to an unused channel and enter the frequency followed by the enter key. Since the choice of bandwidth and modulation is handled by the 800XLT's software, it's automatically set up for AM with the correct bandwidth.

Of course, using software to handle these functions does rely on the programmer's microcode assumptions about the appropriateness of a given mode for a given frequency and doesn't take into account regional or local variation. However, by and large, this method works for most of the frequencies in most of the nation.

A unique feature of the MX-7000 is its bandwidth selection. Although it complicates the setup and programming, it gives you the ability to keep distortion to a minimum because of bandwidth problems. For example, if you are listening to an area of the spectrum that uses 5 kHz narrowband FM, you can program the scanner for 5 kHz reception. It offers 12.5 and 25 kHz bandwidth, too. This ensures clean reception of a particular frequency. On some scanners that use fixed bandwidth, it's possible for a conversation to sound distorted because of bandwidth problems. The proper bandwidth also helps ensure a minimum of crosstalk from other frequencies, and it helps the MX-7000 retain its selectivity.

Coverage

The more ambitious of the two scanners in this face-off is the MX-7000. Like the 800XLT, the MX-7000 is microprocessor-controlled and it is capable of covering 25 to 512 MHz continuously, as well as 800 MHz to 1.1 GHz. This contrasts with the 800XLT, which offers coverage in 12 bands from 29 MHz to 912 MHz. Specifically, the 800XLT covers 29.6 to 29.995 MHz; 30 to 50 MHz; 50 to 54 MHz; 118 to 135.975 MHz; 136 to 144 MHz; 144 to 148 MHz; 148 to 174 MHz; 406 to 420 MHz; 420 to 450 MHz; 450 to 470 MHz; 470 to 512 MHz, and 806 to 912 MHz.

You should note that both scanner manufacturers have finally realized that their units are being used by people other than public service radio monitoring enthusiasts. For amateurs, both scanners will cover the FM portion of 10 meters and the entire 6-meter band. Regency, in fact, has broadened the coverage to include frequencies down to 25 MHz so that its scanner can be used by any radio hobbyist.

As recently as five years ago scanner manufacturers assumed the only frequencies anyone was interested in monitoring were the public service band and the marine band. Now, they realize that their units are routinely used by amateurs to monitor favorite repeater or FM frequencies, as well as by other radio hobbyists. I suspect that much of this has to do with the expanded capability of integrated-circuit-based radio receiving technology. But, whatever its basis, it's a welcomed change.

Specifications

	Uniden-Bearcat 800XLT	Regency MX-7000
Size:	10-5/8 by 3-1/2 by 8	5.4 by 3.1 by 7.9 (inches)
Weight:	5 pounds	2.4 pounds
Power:	117 V ac, 20W, 12 V dc, 9W	13.8 V dc
Battery:	Standard 3-volt (alkaline recommended)	
Receive Sensitivity:	0.3 uV 29–54 & 136–174 0.8 uV 118–136, 60 percent, 1 kHz modulation, 12 dB Sinad 0.5 uV 406–512 0.7 uV 806–912 (±3 kHz deviation 12 dB Sinad)	Narrow FM: 1.0 uV (12 dB Sinad) Wide FM: 1.5 uV (12 dB Sinad) AM: 1.5 uV (10 dB S/N)
Receive Selectivity:		NFM ±7.5 kHz at 6 dB WFM ±50 kHz at 6 dB AM ±5 kHz at 6 dB
I-F Selectivity:	-55 dB at ±25 kHz	-50 dB
Frequency coverage:	29–30 MHz 30–50 50–54 118–135.975 136–144 144–148 148–174 406–420 420–450 450–470 470–512 806–912	26–28 MHz 28–50 50–54 54–88 88–108 108–136 136–144 144–148 148–174 174–216 216–220 220–225 225–336 336–406 406–420 420–450 450–470 470–512 800–1.2 GHz
Channel capacity:	40	20
Audio output:	2 Watts, 10 percent THD	1W at 10 percent THD

Scanning and Searching

Continuing the comparison, both the 800XLT and MX-7000 will scan and search, but the MX-7000 offers even more. It will display the time, retain memory without a battery, and allow you to adjust its receive bandwidth. Both units have a priority scan.

In the memory channel department, the 800XLT comes out the winner with 40-channel capability. The MX-7000 offers 20-channel capability. In its start-up mode, the 800XLT scans the first 20 memories. A second bank of 20 is accessed from the 800XLT's keypad.

Programming

It's easy to see that the MX-7000 is for the serious user. Programming it is far more complicated than you would expect, although it doesn't take long to get used to doing it.

To program a memory channel you must first determine the reception mode (narrowband FM, wideband FM, AM). After you've determined this, you press the manual keypad; then press the NFM (WFM or AM) key and enter. You then punch in the frequency and press enter.

At this point you may think you're done, but you're not. Instead, all you've done is programmed the scratch pad memory. You must now put it into permanent storage in dynamic RAM. To do this, you must press "CH" for channel and enter the particular channel you want and then press enter. As you can see, it takes three key sequences to program a channel, which is far from user-friendly.

On the 800XLT, however, you simply determine the frequency you would like to enter, hit the manual key, advance to the memory you want to store it in, enter the frequency, and then hit enter. It takes only one simple key sequence to accomplish this chore.

Memories

Like the MX-7000, the 800XLT uses dynamic RAM memory. Memory retention is another story—the manufacturers have diametrically opposed positions. Regency, manufacturer of the MX-7000, takes advantage of capacitor-backed memory retention. The MX-7000 uses a high-value bleeder resistor to enable the capacitor to retain as much of its charge for as long as possible. This discharge takes about a week, so memories are retained without the need for battery backup.

Uniden-Bearcat uses a more traditional battery backup for its RAM. But rather than using rechargeable NiCds and circuitry to keep them charged, the 800XLT relies on alkaline cells that have higher voltage but that are only good for a few hours to about a day or so because of the voltage requirements of the memory. Uniden should think of implementing some form of long memory storage in this unit.

Keypads and Beeps

It is also quite apparent when you look at the keypad that the 800XLT is far more user-oriented. It uses real push-buttons, rather than the plastic membrane overlay of the MX-7000. The use of push-buttons gives the 800XLT a far more positive feel and makes it easier to enter frequency information.

The MX-7000's membrane keypad is harder to use because it lacks a substantial feel. If

you don't hit a key in the right spot, you won't get the response you expect, a problem endemic to all membrane keyboards. A beep does sound when an entry is made correctly, but it seems that Regency could have used a keypad with real keys to implement programming. Hand-held manufacturers use real pads on their units, which have smaller areas than the MX-7000 has available.

The Rear Deck

On the whole, the rear of the MX-7000 is far busier than the rear of the 800XLT. On the rear of the 800XLT are connectors for 13.8 V dc, ac, ground, antennas, and memory backup batteries. If you look closely at the rear of the 800XLT, you also become aware of something different. Not only is there a connection for an external VHF/UHF antenna, but there is also a connector for an 800-MHz antenna. Unlike the MX-7000, which uses the standard whip antenna or an external antenna for 800 MHz, the 800XLT uses a separate, fixed 800-MHz antenna, which works surprisingly well.

The MX-7000 has an interesting feature that the 800XLT lacks, an attenuator switch on the rear. Switching it on cranks in 10 dB of signal attenuation to prevent receiver overload. It's a nice touch, especially if you're in the near field of a high-powered transmitter. And while this enables your scanner to remain operating, it does have a drawback in that you will only hear the loudest signals. Weak or distant signals won't get through. It's a good idea to use the attenuation only if absolutely necessary. The rear apron also contains the power, antenna, and external speaker connectors.

The MX-7000 is essentially a mobile unit. As such, it requires 13.8 V dc at all times. When running it off 120 V ac, a special step-down transformer is used. The transformer runs cool, and it easily meets the voltage and current requirements of the scanner. It uses a special triaxial power plug. So, if you're going to use 13.8 V dc you'll have to remember to wire a plug to work correctly.

A nice feature of the MX-7000 is its antenna connector. Rather than using a Motorola-type plug, Regency has used a low-loss BNC connector. The 800XLT uses two Motorola-type connectors.

Performance

The 800XLT turned out to be a good, all-around performer during evaluation. Because of the location of the test site—a hilltop about 335 feet above sea level with a clear shot to the horizon—I was easily able to hear stations up to 35 miles away using the telescoping antenna that came with the scanner.

The 800-MHz stub worked quite well, too, even inside a metal-framed building. The 800XLT is fairly free of birdies. As in other Uniden-Bearcat scanners I've used and evaluated, the birdies were primarily evident in the 40–50-MHz range, as well as the 150–160 range. However, they only appeared on widely scattered frequencies and were no problem.

The MX-7000 was also fairly free of birdies, although it was prone to intermod products in the presence of moderate rf, something to be aware of if you're planning to use it in your shack. The 800XLT was also somewhat prone to intermod.

Specifications

The 800XLT has some good specifications and its performance rivaled them. For example, its sensitivity is 0.3 microvolts from 29 to 54 and 136 to 174 MHz. From 118 to 136—the AM aircraft band—it is 0.8 microvolts at 1-kHz modulation for 12 dB Sinad. From 406 to 512 MHz it has a sensitivity of 0.5 microvolts and from 806 to 912 MHz it has 0.7-microvolt sensitivity with 3-kHz deviation at 12 dB Sinad. Intermediate frequency selectivity is -55 dB at ± 25 kHz.

The MX-7000's specifications were also more than reasonable. For starters, it scans continuously from 25 to 512 MHz and from 800 MHz to 1.2 GHz. It was also one of the first scanners on the market to cover the microwave region of the radio spectrum.

Receive sensitivity is 1.0 uV for 12 dB Sinad on the narrowband FM setting and 1.5 uV for 12 dB Sinad on the wideband FM setting. On AM, the sensitivity is 1.5 uV for a 10 dB S/N.

Receive selectivity is 7.5 kHz at the 6 dB point for NFM; 50 kHz at 6 dB for WFM, and 5 kHz at 6 dB for AM.

Image and spurious rejection is better than -50 dB, while intermodulation rejection is better than 50 dB.

Both scanners are equally capable in the audio department, delivering about 1 to 2 Watts of audio with little or no distortion. This is more than enough for any environment.

As you can see, both sets of specifications are very good, although the 800XLT is hotter than the MX-7000, as the figures show.

Both instruction manuals were clear and concise. They were clearly written and will easily lead anyone through the setup and use of each scanner.

Money Matters

The most serious consideration to be made here, though, is the list price of the MX-7000. At nearly $700, frankly it's too expensive for the casual listener, especially when you consider the $499.95 suggested list of the 800XLT. It is hard to justify spending $699.95 for a receiver when that's nearly the price of a good, mobile HF transceiver that offers more capability for the money. It's also hard to justify that amount of money when others also offer comparable units for less money. However, the final choice is still up to the buyer, and if you're determined to have an MX-7000, you should be able to shop around and find discounts in the vicinity of $250. Still, that's a steep price to pay for a complicated unit.

Heathkit Dual-Trace Oscilloscope

by Paul M. Danzer

Heath Company
Dept. 011-402
Benton Harbor MI 49022
IO-4225 oscilloscope:
$499

The first thing I noticed when I picked up my new Heathkit oscilloscope kit was that it weighed about 30 pounds, including about 10 pounds of carton and shipping material. Quite a contrast to the 75 or so pounds of my soon-to-be retired Tektronix 545.

Make no mistake about it. For a catalog price of $499 (and no surcharge at the Heath retail store) the model IO-4225 is a fully professional instrument meeting the specifications shown in the box—when properly aligned.

My first clue to the complexity of the kit was uncovered as soon as I opened the carton. In addition to the inevitable set of correction sheets to the manuals, there was an additional piece of paper which turned out to be a directory for the shipping carton. This very handy little slip of paper told me where to find the various paper bags of components. The fact that a directory was needed should give you the clue as to how many parts there are.

Construction

Heath sorted out most small components into four packages—numbers 1, 2, 3, and a "final" package. I used two 12 x 16 aluminum-foil baking dishes, with the components of the "final" pack in one dish and one numbered package in the other dish.

Most of the small components come sorted out in order, mounted between two pieces of paper tape. For the initial part of constructing each of the three major boards, each component in turn is taken off the paper tape and inserted in the board. Those who remember assembling early kits will be happy to note that most of the resistors and capacitors are disposed of in this way, leaving few to be identified by hand (and eye). This is fortunate since on the tiny resistors the color code seems to change color when painted upon a brown-body resistor.

Heath sections each board, and construction (or "parts stuffing") proceeds generally from the left section of the board to the right, thus making life a little easier on you. But don't forget: This is not a kit for shaking hands. I found a clear head, a good light, and a magnifying glass (thoughtfully supplied by Heath) absolute necessities. Tiny connector pins designed for automatic machine insertion turn out to be a problem when approached with a pair of hands and long-nose pliers.

I found only one error in the assembly man-

ual. Most embarrassingly for someone at Heath, the error occurs on a correction sheet. An old error is corrected but a new error is made—the instruction step to install R520 is missed.

As you would expect from Heath, all of the holes are drilled in the right places and all of the screws fit, but when you try to wire the horizontal section front panel onto the horizontal circuit board, you probably will find your fingers don't fit.

Test and Alignment

Frankly, I was disappointed in the test and alignment section. The old ohmmeter procedure, carried over from the vacuum-tube kit days, is probably OK if Heath would specify clearly where the positive and negative ohmmeter leads (or the ohmmeter lead with positive voltage on it or the lead with negative voltage on it) go for each measurement. Using an ohmmeter to test wires with semiconductors attached, where the ohmmeter sees the semiconductor junctions, turned out to be a rather hit-and-miss procedure.

The greatest disappointment, however, was with the alignment procedure. Nowhere in the catalog did Heath say you would need precision timebase and voltage-calibration equipment, and those of us used to the old Heathkits which contained built-in test sources are in for a rude shock.

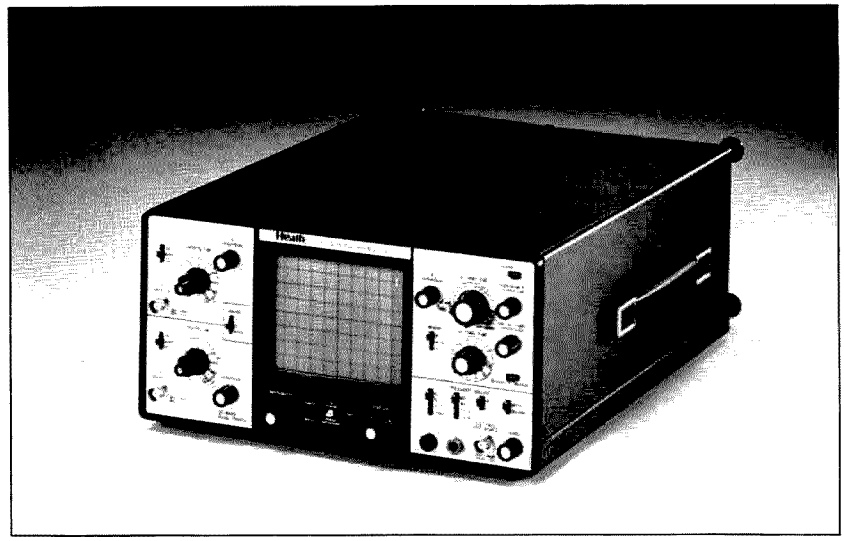
In a telephone conversation with a Heath technician, I was told that there were a few complaints about it but they felt people would use common sense and that the customer would realize that high-quality test equipment would be needed to align a high-quality scope. I guess I am guilty; my common sense, based on prior kits, apparently failed me.

Actually, with a 1-kHz square-wave generator, a variable rf and audio generator, and a good counter a pretty fair alignment can be carried out. The process has to be carried out several times in a row. I found, not to my surprise, that the vertical channels are in fact wideband, high-gain amplifiers which before alignment verge on instability, producing very high-frequency sine waves on the trace seen on the screen. After alignment, all signs of instability seem to disappear.

Circuit Description

As you can see from the block diagram (Fig. 1), a dual-channel wideband amplifier provides a choice of either channel 1, channel 2, or chopped (both). A rather complex attenuator section feeding several gain stages provides an input capability ranging from millivolts to volts.

The horizontal channel provides a choice of a standard sweep ("A" timebase) or a delayed sweep ("B" timebase). The operation of the "B" timebase is outlined in Fig. 2. When you set the "A" timebase, the ramp voltage which provides the linear "A" sweep is compared against a dc voltage set by the time-delay-position control on the front panel.



When these two voltages are instantaneously equal, the circuit says "OK, now I'll start the 'B' sweep." If the sweep-mode control is in the "A x B" position, the length of the "B" sweep intensifies the baseline of the "A" sweep so that you know where you are and what will be shown when you change the sweep mode to "B Delay." When you do change to the "B Delay" position, the "B" sweep is now used, and it starts where you previously set it with the delay control.

Sweep trigger can be selected from an external source or either vertical. Although I have not tried it, it appears that since the sweep selection is independent of the channel selected for display, you can display one channel and use the second as a high-gain sweep-trigger amplifier—a very handy trick indeed.

A few other goodies are provided including a standard TV-sync separator for use in TV troubleshooting, a component tester, and a probe-calibrate voltage for setting probe risetime.

Manuals

As usual, Heath provides a full set of manuals for construction and operation. The manuals are new, have a few bugs, and some strange things are done. As an example, the

The Heathkit 25-MHz dual-trace oscilloscope.

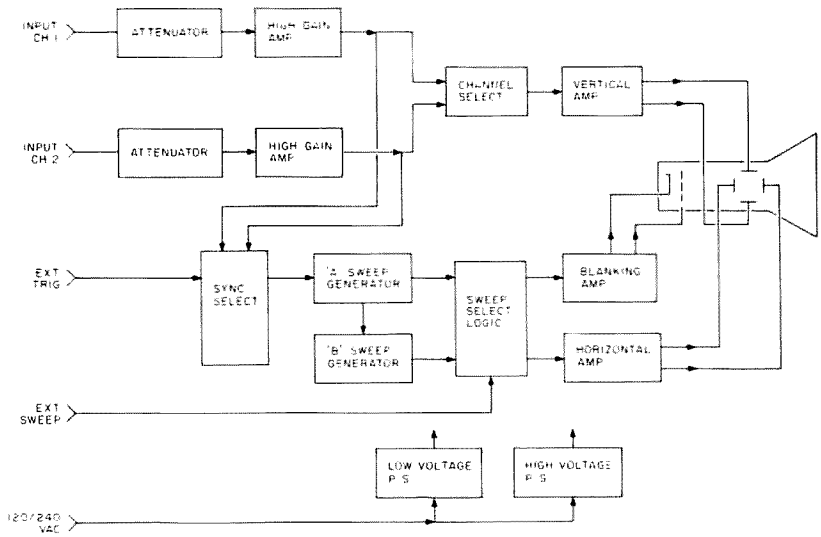


Fig. 1. Block diagram.

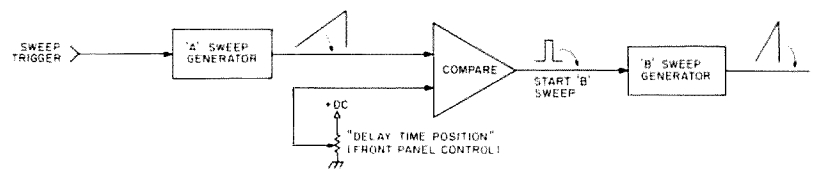

Fig. 2. Delay-sweep generation.

pictorials showing the controls for alignment are not labeled as to which board is which pictorial, a problem you can rectify with a few strokes of a pen. Other errors did not seem to affect anything since the step-by-step assembly instructions are correct (except for the missing resistor mentioned before).

The circuit-description section of the manual is written clearly, but be prepared to deal with such terms as "cascode amplifiers" and "bootstrap" circuits.

Good and Bad

Unquestionably, for about 500 bucks you get a quality instrument; is this kit for you? As far as I could test, using an old Tektronix and a newer Tektronix clone as a reference, the kit lives up to the published standards. Construction is not easy, and good vision, nimble fingers, and at least average color discrimination are needed.

Circuit design seems quite clean and straightforward except for a few cute tricks, such as in the attenuators of the vertical channels. I was surprised how few dual devices and integrated circuits were used—most of the design uses discrete transistors and FETs.

After alignment and realignment, stability appeared acceptable, and the little things such as lack of jumping from range to range as you switched vertical scales seemed to be taken care of. The horizontal trigger system worked as advertised, and was a great improvement over my old Tektronix.

Specifications

Vertical
Dual channel
5 mV/cm to 10 V/cm
3% to 5% accuracy
Dc to 25 MHz
16 nS rise time
1 megohm + 32 pF input

100 mS to 0.1 microsec/cm
3% to 5% accuracy
5X magnifier
External sweep:
- 0.1 V/cm
- 1 megohm + 40 pF

Other
8 cm x 10 cm CRT
20 lbs
6" (H) x 12" (W) x 20" (D)
120 V ac or 240 V ac

If you get the Heathkit IO-4225, plan to spend from $60 to $140 dollars more than the cost shown in the catalog. A minimal scope calibrator, needed for alignment and calibration, costs about $60. Without alignment and calibration, you might as well stick to an old uncalibrated scope. Good probes also are needed if you want to take advantage of the scope rise time and use it for looking at those digital circuits on the bench. Without the probes ($30 to $40 each) you will waste your money on this scope.

My own evaluation: Since I plan to keep this instrument for a long time, the ability to service it myself and get repair parts without canvassing all of the Japanese parts distributors by long distance phone is important. As compared to brand name alternative scopes (and only brand name units), the Heath machine will cost you a few bucks less—or you get a few more features for about the same money. The "fun factor" in building it yourself? Given the size of the kit and its complexity and parts density, this one is either more fun than usual or a bit too much—it's up to you to decide.

DSE Commander VHF FM Transceiver

by Peter H. Putman KT2B

Dick Smith Electronics
390 Convention Way
Redwood City CA 94063
Price class: $150

Got the old kit-building itch? Yearn for the smell of solder? Burnt rosin on your fingertips? Or the many hours spent squinting through a magnifying glass looking for solder bridges? Think of it: when was the last time you built a kit that was really fun?

I don't remember either, but I did have a great time assembling the Dick Smith Electronics Commander VHF FM transceiver—it's a good way to spend a few hours (well, 10 or more). When you're all done, you'll have a 10-Watt synthesized FM rig with full 4-MHz coverage. No memories, no scanner, no bells and whistles, just a plain old two-meter FM rig along the lines of the old ICOM IC-22/22S/22U. With a few qualifications, it works well and is easy to tune up.

Assembly

The write-up of the Commander appeared in the August and September 1985 issues of 73, so I won't elaborate here on its technical specs and performance claims. What I would like to do is address the process of building the kit and aligning it afterwards, as well as a few minor problems and one major problem I found with the unit.

As the kit came from DSE, all of the parts were neatly sorted into various bags. A quick check against the parts list revealed one too many resistors and one too few capacitors—items that were in my well-stocked junkbox. I found individual parts overlays helpful in identifying parts placement, although an all-inclusive parts placements overlay, like the one that appeared in 73, would have been useful. Of course, Dick Smith gives you an "out" in the form of a notice that tells you to return the kit unopened for a full refund if you don't think you can pull it off.

I assembled the kit over the course of four nights: I tackled all the resistors (150 or so) on night #1, the capacitors (175) on night #2, the inductors and transistors on night #3, and the balance of parts and cabinet on night #4—a total of about 10 hours, or 2-1/2 hours per night. This made for a nice work pace. One minor problem I encountered, which I talked to DSE about, is the substitution of capacitors, where physically smaller ceramic capacitors have been substituted for larger disc capacitors. This is all well and good, except when the drilled holes for the larger capacitor won't accommodate the smaller one. Some of these low-voltage ceramics actually break in half when stretched too far, so I do consider this a drawback. Either extra holes need to be drilled, or the correct capacitors must be supplied.

Another problem arose momentarily when it came time to install the front and rear panels with respect to the PC board. The panels actually have to be installed upside down—that is, when holding the unit so that the front panel reads correctly right side up, the bottom of the PC board faces up. This is mentioned nowhere in the literature, but the few minutes I spent studying the placement of the thumbwheel switch with relation to the speaker solved the problem. The front and rear panels are made of single-sided PC-board material, which is easily tack-soldered to the main board for extra strength (not to mention the ground contact for both panels!).

Alignment

Despite these problems, I plowed onward and soon had the front panel completely wired up. You must be careful when making the connections to the thumbwheel switch not to bend the wire too much, as DSE supplies telephone wire for these connections. This type of wire is a bit stiff and really doesn't lend itself well to this type of use. A better choice would have been ribbon cable, preferably multi-col-

ored. This flexible cable sustains bending a lot better. I suggest you use wire ties to group the various clusters of wire whenever possible, especially the power leads and volume/squelch control leads from the front panel.

Make sure you solder the ground return from the speaker output jack to the back plane. Don't depend on the barrel of the jack to make contact, as the hole it goes through isn't plated. I missed this and spent 15 minutes wondering why there was no audio output from the speaker! I also substituted a standard Amphenol SO-239 jack for the one supplied. The Amphenol didn't protrude as far over the circuit board as the supplied jack and made a shorter connection to the rf OUT/ANT connection possible.

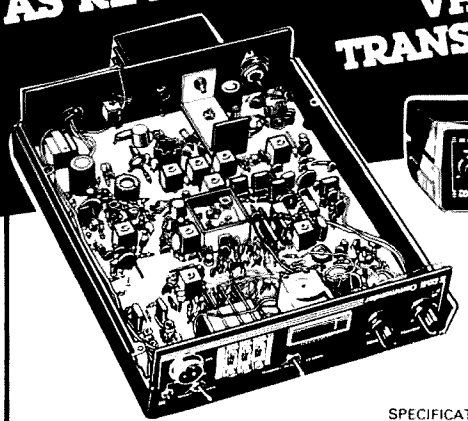
Finally, I had the unit completely assembled. After applying power, I immediately heard a strong local repeater on 146.985 MHz and used it for the balance of the alignment. DSE says you will need a multi-meter, frequency counter, or 2m FM rig, a dummy load (or 50-Ohm antenna if you can't find one) and a 5-MHz oscilloscope or shortwave receiver. Frankly, all you really need is the multi-meter (preferably a FETVOM or VTVM) and counter.

The alignment procedure is easy. The built-in S-meter allows peaking the front end in short order. The other coils that align the vco, offset oscillators, and PLL are quite broad. The counter expedites the reference frequency calibration, and you could almost align the +5 kHz switch by ear. This part of the procedure went quickly. The problems arose when I tried to align the transmitter, which exhibited wild fluctuations in output power that I couldn't tame. The problem turned out to be the vco buffer amplifier, and a quick fix by DSE returned the unit in fine working order.

Few Complaints

In actual use, the receiver is quite sensitive. DSE claims the selectivity to be better than 60 dB ± 25 kHz, which actually is pretty broad. Most commercially made FM rigs exhibit better selectivity figures, and whether this will be a problem for you depends on the density of 2m repeaters in your area, as well as channel spacing.

Where I live in northern New Jersey, I'm in close proximity to about 75 different repeaters. The standard here is 15 kHz channel spacing, and it's enough of a problem even with fairly tight receivers! So I wasn't at all surprised to see signals from 146.79 sneaking in at 146.805, or 147.000 leaking through at 146.985. But the receiver is sensitive indeed, which also aggravates the problem of selectivity. I understand from the manual that 25 kHz repeater spacing is standard in Australia, where this kit originated. It might be advisable to make a tighter filter option available for the United States, especially for those who live near large cities.



As far as the transmitter goes, I received nice audio reports (some stations mentioned a tinny quality to the audio, indicating excessive high-frequency response). One model made by DSE involves increasing the size of the microphone input coupling capacitor to 10 uF from 1 uF to increase low-frequency response. The only adjustment on the microphone audio stage is for deviation and not microphone gain. I prefer both in FM transceivers, since the gain can very well be too high but the deviation can also be too low!

Other reports included excessive leakthrough of hash noise and alternator whine. The DSE Commander does employ a filter network consisting of a choke and capacitor, but it may need to be larger. I don't receive the same reports when using my Kenwood TR-7400. Using windshield wipers and the heater fan also created noise on the transmitted signal. These problems, however, are easily rectified (no pun intended).

This brings me to my major complaint: The audio output is very low for mobile operation, especially in a high-noise environment. The audio stage is rated at 500 mW output (so is the 8-Ohm speaker) and I usually had the audio gain all the way up, at which point I could copy signals most of the time, but that introduced a lot of distortion into the audio product. DSE needs to run at least 2 to 3 Watts output from the audio stage to overcome the absorption of carpeting and upholstery, as well as general ambient noise. I sort of solved the problem with an outboard 3-Watt power module stuffed into the cabinet.

Other than that complaint, this is a fun kit to build, and a useful rig around the house and car. Now, if they could just tighten up the receiver and boost the audio output...

AS REVIEWED THIS ISSUE!
VHF TRANSCEIVER

THE DICK SMITH
2 METER KIT

Nearly 2000 amateurs can't be wrong! That's how many have now built our 2 meter kit in just a few months. Many letters & phone calls have praised the project. In fact a number of customers said they didn't really need another 2m transceiver, they simply built it for the sheer fun of making something again.

The 'Commander' has specs which more than match most commercial transceivers selling for much more. It covers the full 144-148MHz band in 10KHz channels (with 5KHz offset) with full repeater facilities built in. And it delivers around 10-15 watts with a receiver sensitivity of 0.5uV or better! The DSE Commander comes complete with a comprehensive step by step construction manual plus microphone & mounting bracket. Nothing more to buy! Imagine the satisfaction of owning & operating the set you built.

SPECIFICATIONS
Frequency: 144-148MHz in 10KHz steps (5KHz offset)
Mode of operation: FM
Suppy req: 12.8V DC 2.5A (15W output)
Receiver: Dual conversion Superheterodyne
Sensitivity: 0.5uV for 12dB quieting
Selectivity: Better than 60dB at plus/minus 25KHz

Lousy Inconsiderate Dummies

Recognize anyone?

It's my observation that any time two or more hams gather together, their conversation soon turns to the Lousy Inconsiderate Dummies (LIDs) who are ruining ham radio. The subject is not unknown to come up during QSOs, too. So, in my never-ending efforts to be helpful, I'd like your help in trying to identify the areas of expertise into which these lids fall.

Lids most certainly are a major problem for many of us, but before we can tackle the lid problem we have to identify and isolate it so we don't find ourselves diluting our problem-solving efforts by getting off on tangents.

Now, how should we go about classifying lids? Being of an engineering turn of mind, I tend to gravitate toward starting with Lid 01 and working up from there methodically. Perhaps I'm being optimistic—maybe I should start with Lid 001, since it's possible we might go over 99 types of lids! In some ways amateur radio seems to offer limitless possibilities—this may be one of them. I'll stick with Lid 01 for starters, and try not to be too testy if, with your expert lid-identifying help, we're able to describe over a hundred types of lids.

Lid 01. This is the rotten, lousy, dog-mothered SOB who jams nets by insisting on his witless rag-chewing on an Official Net Channel. For instance, the South East Asia Net (Seanet) is an incredible cornucopia of rare DX which can sometimes be faintly heard mornings on the high end of 20m. Two or three Chicago super-lids insist on using what must be at least ten kW to talk a half mile across town with each other every damned morning on the Seanet channel.

Lid 02. This is the ridiculous DX fanatic who suddenly wants you and your buddies, who have been talking on this channel every morning for several years now, to either shut up or move so he can annoy the hell out of a bunch of Asians who have a net on the same frequency and who probably don't want to be bothered by someone from the United States breaking in to get a DX contact anyway.

Lid 03. The unmitigated turkey who suddenly appears on your frequency calling some buddy of his on schedule, making a mess of your contact.

Lid 04. The stupid clod who is talking on your sked channel when your sked time comes up—despite your efforts to get him to move somewhere else in the band so you can hear your buddy—or even to shut up for a couple damned minutes so you and your sked can make contact and find a clearer channel.

Lid 05. The jerk who spends his time kerchunking the repeater, timing it out and making it useless for everone else.

Lid 06. The officious repeater user who insists on call letters being used because "it's the rules and regulations, fella"—despite the fact that everyone talking to each other recognizes who's talking at any time. This chap is quick to point out even the slightest infraction of the rules as he interprets them, often driving repeater users into a frenzy of impotent rage.

Lid 07. This is the senile ham who never, ever allows even one lousy microsecond between transmissions on the repeater. This chap is usually in contact with another 07, complete with an outrageous signal which can't be broken. These old boys can keep a repeater tied up, saying nothing whatever of interest, for hours on end.

Lid 08. This is the repeater mavin who sets his repeater so it times out in 30 seconds, thus assuring that his repeater will never be used for anything of any significant interest. This also makes certain that the repeater will continually frustrate virtually every user, driving the more loosely-coupled ham minds to thoughts of retribution.

Lid 09. This is a subset of 08, the repeater op who sets his timeout at one minute, thus making sure to aggravate almost anyone dumb enough to try and use his repeater for anything beyond kerchunking. His enjoyment is in having it there, taking up a valuable 2m channel, and being able to hear the soul-satisfying kerchunk when he pulls his HT from under his pillow in the middle of the night. Lid 09, when out of bed, is never seen without his HT on his belt. It is never tuned to any other channel than his repeater.

Lid 10. Say, we're getting into this, aren't we? This is the Novice who calls CQ endlessly using Morse code (reputedly used by the fathers of our hobby and memorialized by forcing Novices, who don't know any better, to use it). Morse code was abbreviated as MC in the early days. In an unfortunate accident, the type for a page in an old issue of *QST* was dropped on the HQ floor and the letters were put back upside down. The HQ staffers, being bureaucrats and thus not overly bright, refused to admit their mistake, saddling us forever after with the term CW for Morse code. I thought you might like to know where CW came from. Why the endless CQs? Simple: The Novice, being only able to send and unable to receive, having gotten his license via a good friend, wants to have the fun of transmitting, but doesn't want to be made to look stupid by not being able to copy any responses. The answer is to just send CQ and never listen at all.

Lid 11. This is the Novice who sits and listens to an endless CQ and then tries to call the

CQer, apparently being too dense to realize that the CQer has no intention whatever of responding to a call.

Lid 12. This is the chap who acknowledges, one by one, everything you've said in your transmission and then turns it back to you. Okay on the QTH there...okay on your rig...okay on your antenna...okay on your handle...back to you.

Lid 13. The idiot who makes a second transmission to Lid 12, other than to sign off.

Lid 14. The OSCAR user who dumps a kilowatt into the satellite, thereby overloading it and making it so no one else can use it.

Lid 15. The OSCAR user who complains because I've gone to the trouble to have a good solid signal into the satellite so I can be heard.

Lid 16. The DX fanatic who can't wait for a DX station to sign off with his present contact and insists on tail-ending with his call at every break in the contact.

Lid 17. The operator in a rare DX spot who goes back to tail-enders.

Lid 18. The DX nut who hears a pileup and jumps right in on top just to prove he can dominate the frequency with his rock crusher and twelve-element wide-spaced beam.

Lid 19. The cretin who is too dumb or too lazy to put a decent signal on the air who complains when you make your daily contact with your good old buddy on Lord Howe Island.

Lid 20. The traffic-handling dummy who can't even count the words in his messages right for the check.

Lid 21. The nit-picking net manager who fusses over an insignificant error in the check number—on a message obviously of no consequence whatever which probably will never get delivered anyway.

Lid 22. The inconsiderate lumpen who gets into a sideband rag-chew in the slow-scan part of the band.

Lid 23. The slow-scanner who plops his big signal down on your QSO and sends 15 steady minutes of chirping, wiping out your contact.

Lid 24. The high-speed CW op who's using a Morse-code computer and doesn't even know the code.

Lid 25. The low-IQ jealous CW op who is too dense to set up a computer to copy the code and who tries to make life miserable for the smarter ops who've figured out how to beat the Morse-code problem.

Lid 26. The disgusting old fart who insists on using four letter words on the air.

Lid 27. The old-timer who argues that since even the FCC hasn't been able to define what words can't be aired, why should some asshole object if he uses salty language now and then to express himself? If he doesn't like it he can damned well tune off.

Lid 28. The slow-scanner who sends endless *Playboy* and *Penthouse* centerfold pictures, filling the slow-scan part of the band, which is narrow enough as it is, with junk.

Lid 29. The slow-scanner who complains about someone sending beautiful pictures over the air—something a lot more interesting to watch than the hundredth dumb picture of a shack or a ham's ugly wife and kids.

Lid 30. The chap who calls you because he needs a QSL with your prefix, or from your state, your county, your zip code, or some other such impersonal reason. Why should you waste your time and postage on some jerk who has decided he is going to make WAS in 24 hours on 75m phone?

Lid 31. The ham who promises you a QSL for your Ten Band WAS and then doesn't send it.

Lid 32. The DX operator—usually in a very rare country—who refuses to respond to your QSL.

Lid 33. The DX op who sends his QSL to a rare country op or his QSL manager with the wrong date and/or the wrong time, making it a bitch to check the log. No IRC enclosed, of course. Doesn't this chap realize how much postage costs these days?

Lid 34. The first-time DXpedition operator who operates outside the American phone band and asks for calls between 14.100 and 14.200.

Lid 35. The DXer who jumps up and down between 14.100 and 14.200 calling the DXpedition on random frequencies, thus ruining contacts in progress in that band. Lid 35a is the slightly smarter DXer who listens with a second receiver or with one of those newfangled digital receivers to the DXpedition channel and also tunes the 14.100 to 14.200 band to hear where the DXpedition is listening—then jumps on top of the frequency and never mind who is already there.

Lid 36. This is the DXpedition or operator in a very rare country who is working an endless list provided by some cohort.

Lid 37. The DXer who gets nasty because he isn't on the list.

Lid 38. The mobile dingle who is driving to or from work and talking via the mountaintop repeater to a fellow dingle a half mile away. Much of the conversation has to do with expert criticism of observed poor driving practices in his vicinity, a subject of obvious deep interest to the dozens of chaps waiting to use the repeater.

Lid 39. The high-powered 2m op with a big beam who sits all day tying up the local repeater.

Lid 40. The mountain-topping frustrated DXer who ties up a half dozen repeaters on a channel trying to make a contact through just one of the repeaters.

Lid 41. The repeater user with absolutely nothing whatever to say who won't wait for a mountain-topping DXer to make a contact through a distant repeater, but instead uses a local repeater and makes the DX contact impossible.

Lid 42. The flying repeater user. This chap can tie up even more repeaters than the mountain-top DXer. His big complaint is the length of some of the squelch tails on some repeaters on the channel he's picked.

Lid 43. This is the dope who is eagerly trying to get through to the flying lid, tying up his local repeater and making so much hash on the channel the flying lid is unable to really hear anything.

Lid 44. The packet-radio op on the lower bands whose rig keeps endlessly repeating a message because his rig doesn't get perfect copy due to QSB, QRM, or QRN.

Lid 45. The CW op who gets frustrated by a packet-radio station and gets even by jamming it—resulting in the packet rig endlessly (and mindlessly) repeating the message.

Lid 46. The DXpedition operator who asks for donations to help defray the cost of the trip.

Lid 47. The DX operator who is too chintzy to help out with the incredible costs involved with putting on a DXpedition and who could easily afford to send along at least a tenner. If he's on the Honor Roll he's a cheapskate if he sends less than $100.

Lid 48. The DXpeditioner who operates from somewhere else than where he says he is, figuring what difference does it really make? After all, DXers can make contacts anywhere in the world and where you are is no less difficult for most of 'em to work than if you were where you said you are. I believe this approach was pioneered by WØMLY in his infamous operation in North Africa. Every contact counted for ARRL credit, so what the heck, right? I've gotten a whole bunch of QSLs for DX contacts where the operator wasn't really there—and they all count.

Lid 49. The DXer who pauses for one instant before making a DX contact just because the operator may not be where he says he is.

Lid 50. The unconscionable, fatherless chap who uses a rare DX call with reduced power just to have the fun of being on the power end of a pileup for a while. No, not one of the thousands practicing this deceit has ever been punished for this, but the freedom from fear of being caught should not encourage this outrage on innocent, trusting DXers.

Lid 51. The DXer who refuses to work a rare station because he suspects it may be phony. True DXers may complain, but they observe the fixed rule: Work 'em first and bitch later.

Lid 52. The ego-driven maniac who decimates a pileup to work a very rare station and then, after the contact, jams the channel to keep anyone else from working the rare one.

Lid 53. The Honor Roll DXer who gets a new one and then doesn't do everything in his power to keep his competitors from keeping up with him. Ruses include jamming the DX, asking the DX to move to 80m for a try, asking all sorts of questions which will keep the DX op busy answering until propagation has changed, and so on.

Lid 54. Contest operators who leave open numbers here and there in their contest logs to be filled in with mythical contacts (with missed countries, sections, or whatever) so a log cross-check won't give them away.

Lid 55. The contest op who doesn't use every known stratagem to win the contest. After all, his competitors are going to. If this means claiming 90 Watts out when more like 5,000 was used, who's to really know?

Lid 56. The ham club president who does all he can to keep young hams from messing up his club.

Lid 57. The youngster who comes to a ham club meeting made up entirely of old-timers—which is about what there is to choose from these days—and shuffles his feet when bored.

Lid 58. The ham who brags that he doesn't have any QSL cards when you ask him for one to confirm your contact with his state, section, zip code, county, or area code.

Lid 59. The ham who sends out a QSL for every contact he makes, creating guilt feelings with type-58 lids who don't have any QSL cards and are too damned rotten chintzy cheap to buy any.

Lid 60. A QSL fanatic who gets every QSL he can and indexes 'em in a big filing cabinet so he can pull yours out every time you contact him and make you feel guilty for not having his at hand.

Lid 61. The information fiend who makes a note of everything you mention during a contact and then, the next time you work him, even if it is years later, has total recall of the last contact.

Lid 62. The obviously brain-damaged operator who has no recollection whatever of his contact with you last week—or last month. The SOB doesn't even remember your name.

Lid 63. The op who has to be reminded every other transmission of your handle—or who never gets your call right twice in a row.

Lid 64. The nitpicker who is so organized that he writes down your name and call and thus never has to be reminded of them during a contact—proof positive of little imagination or creativity.

Lid 65. This is the cliché-er who will see you further down the log because he has to pull the big switch and modulate the mattress.

Lid 66. The ham who puts up with a cliché-user without screaming at him, suggesting he go back to CB where he belongs.

Lid 67. The ham who cheated to get his license and refuses to ever discuss anything technical so he won't give away his total ignorance of electronic technology and radio.

Lid 68. The frustrated pseudo-engineer who, at the slightest provocation (or with none at all), plunges into a deep technical treatise on something you have no interest in whatever. Any ham with some technical smarts will recognize immediately that this lid is full of partly-understood theory.

Lid 69. This is the chap in a round table where there are some YL ops who thinks it's cute to make constant double-entendre remarks, thus making the YLs and everyone else uncomfortable.

Lid 70. The YL with no sense of humor, who objects to being called OM and gets huffy at sexist remarks.

Lid 71. The self-important ham who quickly brings up his Jaguar, his twin-engine plane, his yacht, and other boring things.

Lid 72. The world-traveler who calls rare DX stations and sets up dinner meetings with them.

Lid 73. The ham magazine editor who, with obvious false modesty, doesn't mention Who He Is, thus making his contact feel like a real jerk when he finally figures it out—often after signing and hearing another station calling frantically to work said "famous person."

Lid 74. The ham who is so totally unread he doesn't know who the editors of the four ham magazines are so he'll recognize one when he hears him. This chap probably wouldn't even recognize Barry Goldwater if he worked him.

Lid 75. Any ham who tries to solve his own TVI problems without the help of fellow hams as intermediaries.

Lid 76. Any ham who refuses to help another ham with his TVI problems.

Lid 77. Any ham crazy enough to lend a fellow ham his rig while he's on vacation. The rig will never again be the same. There is only one case in all ham recorded history of a rig being returned in better condition than it was when borrowed and that ham is now living in Borneo (V85AA).

Lid 78. Any ham who borrows a rig from a ham going on vacation and expects the lender to ever again be on speaking terms after noticing the big scratch your junior op put on the front panel. (That's the scratch even the black magic marker couldn't hide.)

Lid 79. Actually this is a group effort—hams who turn up in a skiing village with their HTs and take over the local repeater for a few days, leaving the locals—the chaps who paid to put it up and keep it working—substantially irritated.

Lid 80. Local ops who fuss because a few visitors use their precious repeater for a couple of days.

Lid 81. The QRP fanatic who wants you to move over or shut up so he can make a tenth-Watt contact somewhere he shouldn't—often with some rare DX op who should better spend his time working stronger signals.

Lid 82. Mobile ops who add to the QRM by trying to work DX beyond their depth.

Lid 83. The 20m rag-chewer who steps all over QRP and mobile ops who are trying to do the impossible so they can get a lousy mention in *QST* for them to make into a plaque and hang on the shack wall.

Lid 84. The 3999er who insists his signal is not outside the band.

Lid 85. The 80m CW op who makes it a point to walk all over DX phone stations who operate in his CW band.

Lid 86. The 75m DXer who believes it is his right to work DX phone stations operating in the CW part of the band.

Lid 87. The Italian operator who spellsa everythinga for youa twice-ah.

Lid 88. Guess who.

Lid 89. Any YL ham who bridles at me writing "guess who" for Lid 88.

Lid 90. The 75m AMer who is obnoxious about being so far behind the current ham technology.

Lid 91. The 75m SSBer who makes it a personal vendetta to harass the 90s.

I'll leave a few for your suggestions. I suspect I haven't even really begun to tackle the lid problem we face as yet—so let's get the list over 100 and see where it goes. Once we get the list in shape, perhaps I should print it in poster form so you can hang it on your shack wall along with all your dumb certificates and other trivia to which you've dedicated your life—the stuff your kids will have to throw out, along with all those old worthless ham magazines, when you get your last mention in *QST*. ■

Lids, LOTMs, and ATLHR

Be assured that if you make an outstanding name for yourself in any one of the lid categories you could live in infamy well beyond your one-line Silent Key obit. Several hams have made my All-Time Lid Honor Roll—W2BIB, W2HH, W2OY, W0MLY, W1BUD, W2KR, and so on. What was Don Miller's call? Oh yes, W9NTP. I'll bet you have some nominations for the ATLHR.

If you have a favorite you think should be nominated for the Lid Of The Month (LOTM), send me his call and documentation to back up your nomination. I'll increase my libel insurance and we'll see what we can do to clean up this awful mess. We amateurs are supposed to be self-policing, aren't we?

No, I don't want to see vigilantes going out and lynching miscreant lids, no matter how soul-satisfying it would be. I remember when a bunch of Brooklyn hams got fed up with a local lid who would work only Spanish-speaking stations and who was very rude about this to his neighbors. A committee was formed to explain how the W2s felt. It was a large committee—not in numbers, but in weight—and it established the needed rapport. When he healed, the chap had a much better perspective on his new friends and was very nice on the air after that.

Y'all write, y'hear?...Wayne.

Speed-Charge Your PB-21

This ac/dc charger gets your TH-21AT off your belt and on the air.

Here's a way to increase the usefulness of your Kenwood TH-21AT by quick-charging the battery pack. Most people like the small size of the HT but complain about the limited battery life. The way to keep things running smoothly is to get two batteries and use one while quick-charging the other.

I don't think that Kenwood offers a quick-charger for the PB-21, and the five-to-six-hour wait for the standard 110-volt charger isn't acceptable for sustained operations such as public service events. If you're not near a 110-volt source, the problem is further compounded.

The solution is to build a charger which accepts both 110-volt ac and 12-volt dc. This permits you to charge the battery from your vehicle's cigarette lighter. The nominal voltage of the HT battery is 7.2 V, and 12 volts will charge it quite readily.

Charge Rates for NiCds

As a bit of a side note, I'd like to describe the charge rates that can be applied to nickel cadmium batteries. Most of them can be fast-charged at their milliamp/hour rating for an hour, or slow-charged at one-tenth their milliamp/hour rating for 10 hours. For example, a 180 milliamp/hour battery can be charged at 180 mA for one hour (180 x 1 = 180), or 18 mA for ten hours (18 x 10 = 180). Fast-charging shouldn't continue for more than an hour because the cells will overheat and possibly be damaged by excessive gassing. The slow-charge rate can be maintained indefinitely with no cell damage.

This charger was designed to provide both a quick- and a slow-charge rate, but doesn't switch between the two automatically. Some vigilance is required from the operator in order to avoid cell damage. It's assumed that users will be involved in extended periods of operation and will be rotating batteries. Therefore, you should stay nearby to tend to the charger and extra pack.

Circuit Details

Fig. 1. reveals the plan. The output of the rectifier is the point where 12 volts dc is applied from some external source. This potential is assumed to be the 12 volts from your vehicle's electrical system, although it can be any other dc source. Be sure to fuse this input for safety.

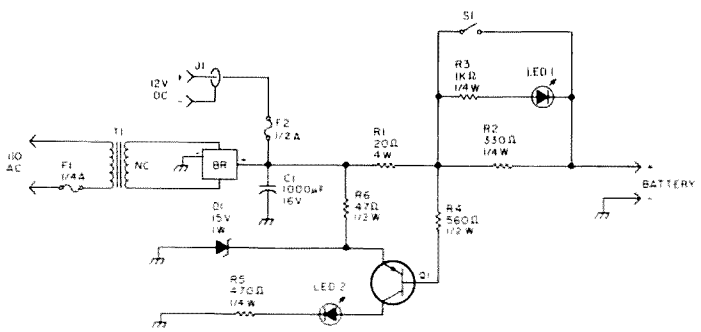

Fig. 1. Schematic of quick- and slow-rate charger for Kenwood PB-21 battery pack. This circuit can be used for just about any handie-talkie battery pack. Change the values of R1, R2, and F2 for the charging current needed.

The unit uses a 12-volt power transformer, bridge rectifier, and filter to provide the charging potential from 110 volts. This is relatively straightforward, but you should note that the transformer center tap isn't connected. The entire secondary voltage is applied to the rectifier. Regulation and ripple in the dc output aren't a concern because the potential is used to charge a battery and not power an amplifier. We have no intention of listening to a signal. No power switch is provided since no current will flow unless a battery is under charge. The battery is, in effect, the on/off switch. However, don't forget to fuse the primary of the transformer.

R1 limits the quick-charge rate to approximately 180 milliamps, which is the rating of the battery. R2 sets the slow-charge rate at 20 milliamps. LED 1 indicates low-charge-rate current flow and R3 limits voltage across it. Switch S1 shorts out R2 and the R3-LED 1 combination, allowing the higher current necessary for quick charging; this current develops enough voltage across R1 to foward bias Q1 through R4. Q1 functions in the circuit as a switch, and is driven into conduction by the applied bias. When Q1 is on, current flows from the emitter to the collector and turns on LED 2, indicating high-charge-rate current flow. Use a blinking LED to draw attention to the fact that the battery is being quick-charged. Resistor R5 limits voltage across LED 2 and R6 helps to set the bias point of Q1. Zener diode D1 protects the transistor in case a reverse-polarity voltage is accidentally applied to the unit.

Most of the parts used are garden-variety items with no critical or unusual components. Feel free to substitute. A discarded AM/FM circuit board can provide most of the parts. If you have a well-stocked junk box, you can probably build this charger for nothing. If not, some careful shopping at the next swapfest should yield everything, with the cost limited only by your ability to bargain. If

all else fails, your friendly neighborhood Radio Shack should have all the necessary parts, except for the spring brass used for the battery contacts. Even here you may be able to use contacts from one of their battery holders. With Radio Shack as a parts supplier, the total outlay shouldn't be more than $35, according to their 1985 catalog. This price may seem high, but it assumes you have to actually purchase everything.

Beginning Construction

Begin construction by carefully cutting a slot for the Kenwood battery at one end of the project case. Mark the slot with a pencil by tracing around the battery; cut the opening slightly undersize with a keyhole saw. Then use a flat file to get it to the final size. Work slowly and don't let the opening get too big. It should hold the battery firmly in an upright position, and not allow it to rattle around or shift in the opening. This prevents loss of contact when the charger is used in a vehicle that is in motion. Remember, if there is no contact with the battery, no charging takes place.

The project case suggested has internal slots for circuit boards, and this method of mounting is used for the power supply. The transformer is the bulkiest item, but with a little care all of the items can be placed on one vertical board.

A second board is used for the battery contacts. This one is mounted horizontally on four long screws that function as posts. Put extra nuts on both the underside and the top of the board to provide a firm platform for holding the HT battery (see Fig. 2).

Now comes the only real home-brew portion of this project, and it requires some resourcefulness on the part of the builder: The charging contacts of the battery should be made from some sort of spring brass or shim stock. I fashioned mine out of a piece salvaged from a discarded doorbell switch. The brass strips were cut to match the contacts of the HT battery pack. I drilled one end of the strips to accept a mounting screw and attached them to the circuit board. Next, the strips were carefully bent into a horseshoe shape to provide the spring necessary for good contact. In use, the weight of the pack against the springs makes the required connection for the charging current. I recommend that brass hardware also be used for mounting to keep electrical resistance low.

Now construct the power-supply board. This one should slip into the slots provided inside the project case. An etched board will add that commercial touch to the project, but point-to-point wiring will work as well. Once the cover is on, no one but you will know the difference.

Because of the small number of parts and the room for liberal substitution, I haven't provided a circuit-board layout. If your junk box yields something that will work but is different in size or lead configuration than the part specified, such a layout would have little value; hence, the builder is left to determine the best component placement.

I found the following steps convenient: The

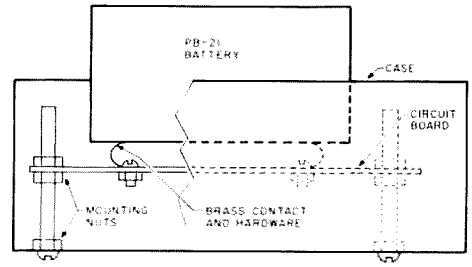

Fig. 2. End view of case and cut-away portion showing brass charging contacts and method of supporting the battery while in the charger. Drawing is not to scale.

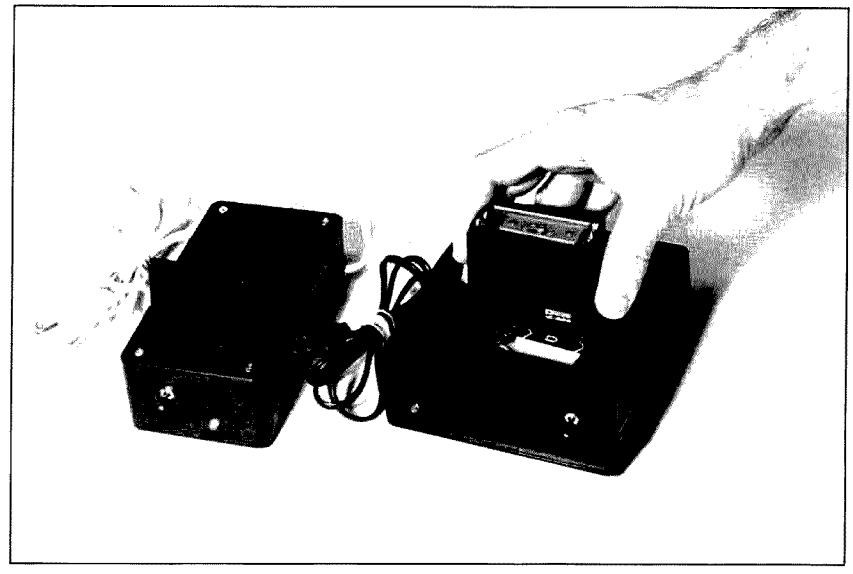

Photo A. The charger described in this article is shown on the left. The photo gives a good view of how the battery pack is held while being charged. The unit on the right uses the same circuit, but the values of R1, R2, and F2, along with the power transformer, have been changed for the higher current required by the ICOM BP-4 pack. Construction of this unit preceded the one described in the text.

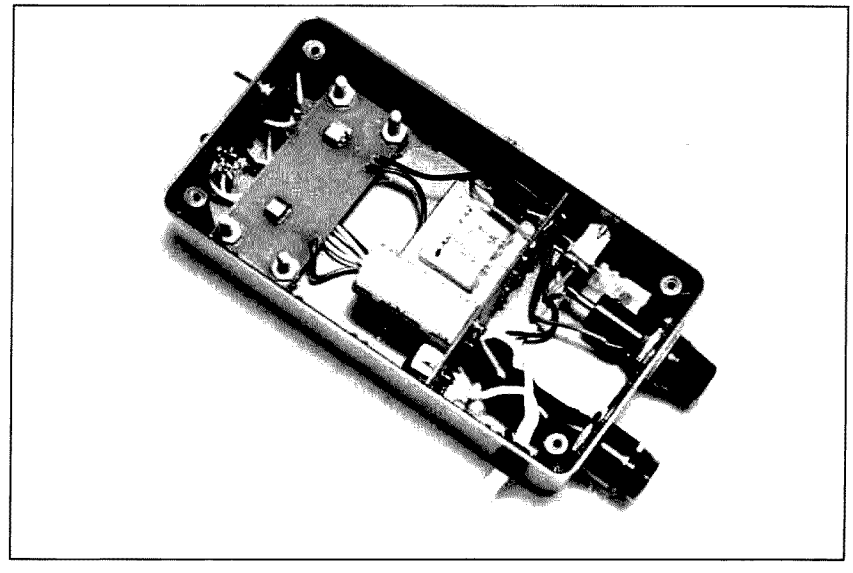

Photo B. Here, the unit is shown with the cover removed. At the left is the circuit board and charging contacts that support the battery while it is being charged. In the center is the power-supply board. At the right are the power connections. Clockwise from top they are: 12-volt dc input, 12-volt fuse, 110-volt primary fuse, and line cord.

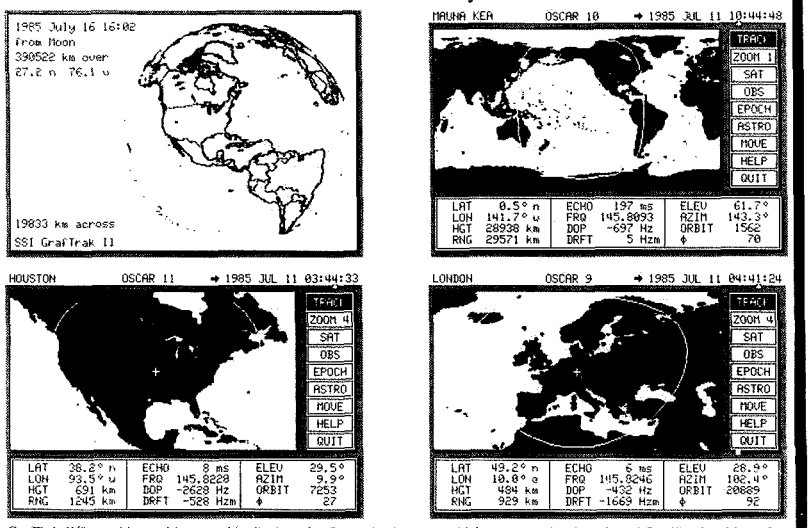

transformer should be mounted first. Put it low on the board so that it will be near the bottom of the case and the circuit board won't be top-heavy. Putting the primary connections at the bottom keeps the exposed 110 ac to a minimum—a good safety move.

Parts List

Part	RS#	Description	Price
BR	276-1146	Bridge rectifier, 4 A, 50 Piv	1.39
C1	272-958	1,000 uF, 16 Vx2	.99

GET A BIRD'S EYE VIEW

From GrafTrak II™ and your IBM® PC

GrafTrak II™ provides realtime graphic display of a flat projection map which moves under the selected Satellite/Sun/Moon/Star coverage circle and updates once per second. Spherical projection views and graphic screen dumps to an IBM/Epson/Oki printer can also be produced. Requires an IBM PC, PC/XT, PC/AT, or true compatible, an IBM Color/Graphics Monitor Adapter or true compatible, 8087 math coprocessor, minimum 256K RAM with 512K recommended, DOS 2.0 or later, and either two 360K floppy drives or one 360K floppy and one hard drive.

SILICON EPHEMERIS™ provides tabular data output to the screen, printer, or disk file for the following operating modes: 1 observer to 16 satellites, 16 observers to 1 satellite, schedule for 1 observer to 1 satellite, window between 2 observers and 1 satellite, rise and set times for 1 satellite, time ordered rise and set times for 16 satellites, Almanac for Sun and Moon, 16 observers to Sun/Moon, schedule for 1 observer to Moon, window between 2 observers and Moon, schedule for 1 observer to Sun. Requires either an IBM PC, PC/XT, PC/AT, or true compatible, and IBM Monochrome or IBM Color/Graphics Monitor Adapter or ture compatible, an optional 8087 math coprocessor, 256K RAM, DOS 2.0 or later, and one 360K floppy drive.

Each package includes SED, an editor program to construct and modify Satellite/Observer database files. These products can be run from a hard disk and are not copy protected.

GrafTrak II™ and SILICON EPHEMERIS™ are priced at $119.95 each or $199.95 for both. Texas residents add sales tax. Order by check, money order, MasterCard, or VISA.

Silicon Solutions, Inc. • P.O. Box 742546 • Houston, Texas 77274-2546 • (713) 661-8727

Next, mount the filter capacitor, since it is also somewhat bulky. The other items occupy little space and can be placed at will, but give some regard to the heat generated by the power transformer. When the circuit boards are complete, set them aside. Mark and drill the case for the fuse holders, power cord, switch, LEDs, and 12-volt-dc connector. Mount these items and proceed with the final wiring. I chose to simply glue the LEDs into the proper size hole. Allow extra length in the wiring to facilitate servicing.

When complete, check the charging current by using clip leads and an ammeter. Typical values should be 18-24 mA for the low rate and 180-200 mA for the quick rate. If all is satisfactory, put the unit into service.

Using the Charger

At this point, I'd like to include several notes on the use of this charger. As I mentioned, the battery pack should *not* be left on fast-charge for more than one hour. Doing so may damage it. Since the charger doesn't automatically reduce the charge current, some care is required. Don't forget that the battery is on fast-charge.

If the battery isn't needed at the end of one hour of fast charging, switch to the low rate. It can be on low-charge for an extended period of time without damage.

I've been using this charger for more than three months with no problems. It has been used during public service events to fast-charge from a 12-volt automobile battery. I did manage to fry one battery, but that was due to my own forgetfulness.

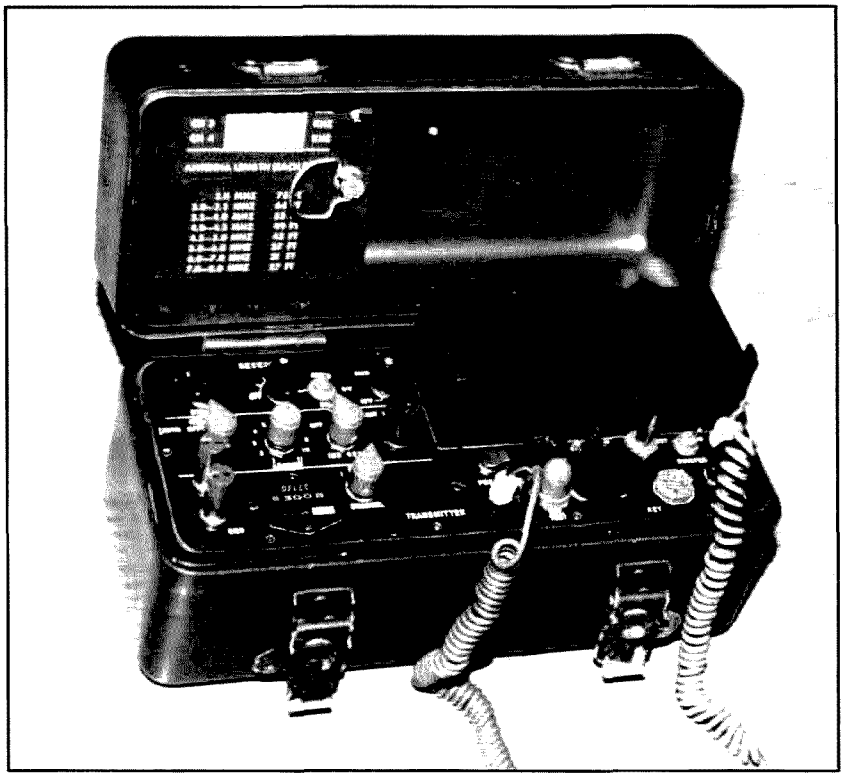
Kenwood says nothing about fast-charging the PB-21 battery; therefore, I don't recommend using this charger while the battery is still under warranty. The battery must be removed from the TH-21AT for charging.

This basic circuit can be adapted to just about any HT battery pack. As shown in Photo A, the forerunner to this project was a quick-rate charger for the ICOM BP-4 containing six AA cells. The only problem that developed with this version was oxidation of the brass contacts.

The objective of the charger cicuitry is to limit charging current flow at the quick-charge rate with R1 and to the low rate with R2. Some manipulation of Ohm's Law will give you values for these components.

Make sure the secondary of your power transformer can supply adequate current or it may be damaged. Some overload can be tolerated, since quick-charge current is drawn for a limited time. As I have described, S1 shorts out R2 to provide manual selection of the charge rate.

LEDs 1 and 2 are used to indicate that there is good battery contact and that there is a charging current flow. They won't light unless there is current flow. I prefer to use green or yellow for the low rate, and a flashing red for the high rate, which is better at getting the operator's attention.



Thanks go to Don Kollmorgen K8VIG for his help and for the photos used with this article. Have fun building! ■

Army Surplus CW

Simple conversion tips for the Special Forces PRC-64.

The Delco 5300B, the CIA version of the PRC-64 transceiver.

The PRC-64 is a small, lightweight portable transceiver used by the Special Forces which frequently turns up at flea markets. Although the manual specifies a frequency range of 2 to 6 MHz, experience with a variety of units has shown that this set easily covers the 160-, 80-, and 40-meter amateur bands with no modification.

The set is housed in a waterproof aluminum case, weighs 7½ pounds, and is capable of either AM or CW operation. The rig includes a 6-kHz ladder filter for AM and a 500-Hz Collins mechanical filter for CW. It also features a panel-mounted hand key and CW sidetone. Stated rf power output is 1½ Watts for AM and 5 Watts for CW, but these figures are based on minimum battery voltage; rf output is nearly doubled for either mode with nominal battery voltages applied to the transmitter stages.

Variants

It's good to keep in mind that you may encounter variants of the PRC-64. The Delco 5300 is the CIA version of the PRC-64, but it is electrically and physically the same. The PRC-64A includes an oscillator control circuit that prevents chirping and key clicks when transmitting CW at 300 words per minute with the GRA-7 Burst Encoder. The third variant that we've seen appears to have been produced in a very limited quantity. It can be easily identified by its lack of a bandwidth switch and its microswitch hand key. There are also at least two frequency-synthesized variations of this rig; the Delco 1600 is frequency-synthesized from 2 to 10 MHz, has a tunable receiver, and features AM modulation. The Delco 3200 is the same except that it has single-sideband modulation.

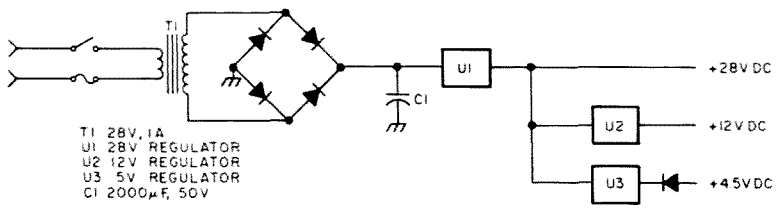

Fig. 1. Power supply.

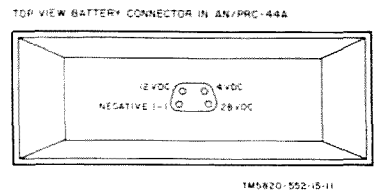

Fig. 2. Pin connections for input voltages.

Crystals

The receiver requires crystals in CR-78/U holders. The receiver crystal frequency should be the desired frequency plus 455 kHz. The transmitter requires crystals at the operating frequency in CR-89/U holders. For those of you with the Delco 5300, some, if not all, of these sets use CR-78/U holders for both the receiver and the transmitter. Check the pin spacing of the transmitter crystal sockets before ordering crystals.

You can order crystals from Sentry Manufacturing Co., Crystal Park, Chickasha OK 73018. The price is $10 each for the receiver crystals, and $13 each for crystals used in the transmitter.

Power Supply

Power for the PRC-64 was originally supplied by a BA-1509 magnesium battery, which produced 4 volts for the receiver, 12 volts for the oscillator, and 24 volts for the transmitter final stage. This battery probably isn't available now, so you'll have to construct either an ac power supply or a battery pack. The schematic for the power supply is shown in Fig. 1. Pin connections for the input voltages are shown in Fig. 2. The female plug for this connection is a Cinch-Jones number 13279. The 70-mA current requirement of the transmitter rules out the use of ordinary dry cells, so if you are contemplating portable operation, the battery pack should be built using heavy-duty NiCds.

Once you have a suitable power supply built and your crystals have arrived, you can proceed with the tune-up phase. We suggest that you double-check your connections before you accidentally hit the switch. Applying 12 or 28 volts to the 4-volt pin means instant death for the receiver.

Tune Up

To tune up the rig you'll need a 10-Watt, 50-Ohm resistor, a couple of tweaking sticks, and a 600-Ohm headset, if you aren't fortunate enough to get the original earphones. Install the receiver and transmitter crystals in their appropriate sockets. Each channel covers only a specific frequency range, as follows: channel 1, approximately 1.9–2.8 MHz; channel 2, 2.8–3.65 MHz; channel 3, 3.6–4.7 MHz; channel 4, 4.6–7.2 MHz.

To tune up the receiver, set the receive-send switch to receive, the bfo to off, the B/W switch to 6 kHz, the gain control to maximum, and the receiver channel switch to the proper channel. Connect the 50-Ohm, 10-Watt noninductive resistor between the antenna and ground terminals. Referring to Fig. 3, adjust the rf collector coil for this channel for maximum noise in the headset.

To tune up the the transmitter, set the receive-send switch to send, the loading control to 1, the AM-CW switch to CW, the IND-SENS switch to 3, and the transmitter channel switch to the proper channel.

Refer to Fig. 4 and adjust the driver coil and final amplifier coil for this channel for maximum brightness of the antenna indicator lamp while depressing the panel telegraph key. Turn the IND-SENS switch to the lowest number that will give an indication and again adjust the two coils for maximum brightness of the lamp.

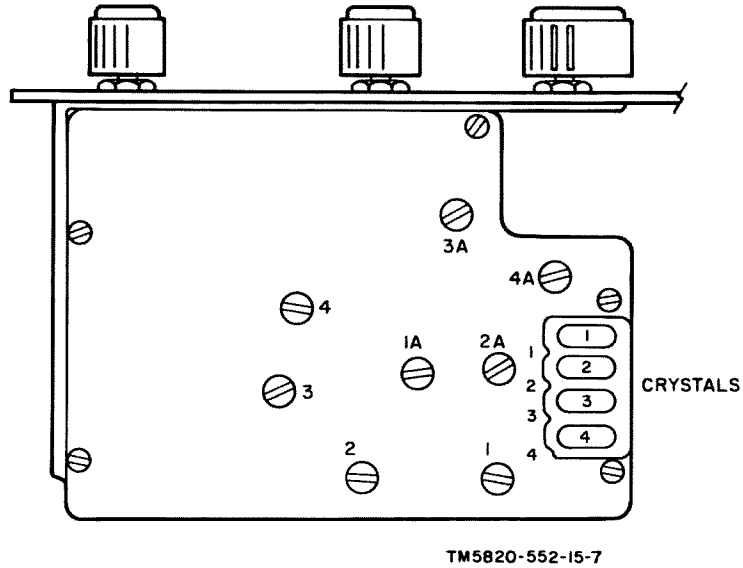

Fig. 3. Use this map to match the channel number to the appropriate rf collector coil.

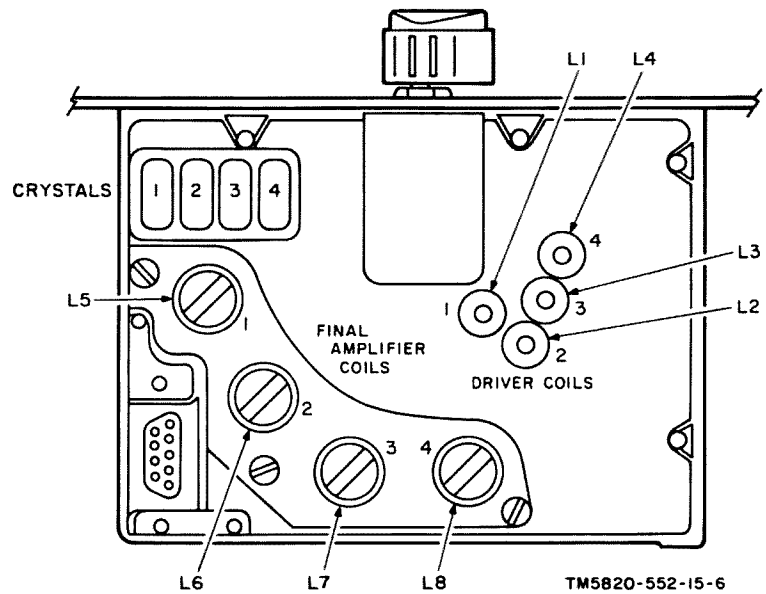

Fig. 4. Final amplifier and driver stage tuning adjustments.

Manual and Accessories

The technical manual for this rig is TM 11-5820-552-15. It is available from most dealers of surplus manuals. We also have a few copies. For AM operation, a standard dynamic microphone works well. The earphones are 600 Ohms. (The earphones from the PRR-9 rig work well.) The rig was originally furnished with a 50-Ohm dipole antenna wound on three reels, but any standard antenna from the handbook works well with this rig. For replacement transistors in the receiver, 2N207 will replace all but the audio transistors. The equivalent number of audio transistors is 2N706A.

External Key

An external key, or electronic keyer, may be used by plugging the key into the socket provided for the high-speed burst keyer. Wire the keyer to pins A and D of an Amphenol 125–195 plug. Ground is pin A.

In summary, the PRC-64 is an excellent portable or emergency QRP rig that is readily available at a reasonable price. It requires no conversion other than a tune-up and the acquisition of the crystals and accessories.

We'll answer any questions from amateurs who have either experience with this rig or questions about it. We are also interested in talking to anyone who has experience with synthesized versions. ■

The Day the Aliens Landed in Limerick, Maine

There once was a ham in his shack . . .

As a general rule, I go to bed early (7 p.m. or so) from October to May. That way, I can get in five or six hours of sleep, awake refreshed at 1 or 2 in the morning, and get on 75-meter phone ready for the European and African DX.

My routine is to sneak out of bed so as not to disturb the XYL, feed my two Tanganyika Terriers, make a pot of tea, and settle down to pick up a country now and then, to help out on the 75-meter DXCC. Some mornings I hear little or nothing of interest, so I read or doze off in the chair. My operating position faces a window that looks out over a five-acre field where I have a pair of 40-meter verticals, a few big delta loops, and about ten cords of wood stacked up for the winter.

It's a Plane, It's a ...

One morning in early February, I was listening to a W2 working a CEØ on Easter Island. The W2 was one of the Big Guns on 75 with a 75-meter beam up 140 feet. He was giving the CEØ a 59 plus and turned it over to the CEØ, whom I copied between a 3 or 4 and signal strength the same. When the W2 signed, I called the CEØ but he came back to a W3. After four more tries, I finally snagged him and was grateful for the 34 he gave me.

There's not too much activity at 2 in the morning from W1-land, but a few W1s and W2s called the CEØ, and I half-listened while drinking a cup of tea.

All of a sudden, the band went dead—by dead, I mean nothing, absolutely no sound from the receiver. I figured the headphones had gone sour. I unplugged the phones and still heard nothing. I thought the 830S had "bought the farm" for sure. I could see myself packing it into the box and shipping it off to W6 land for repairs.

Since the window in my shack is in the back, as I looked at the receiver I noticed light, and it was getting brighter. Now, at 2 a.m. it just isn't natural to see light out in my back yard. Two steps took me to the window, where I damn near had an embolism! Looking straight out into the field and directly over the tops of the big pines that border the field, I saw a large object hovering and lighting up the entire area. As I looked, a row of lights came on and were directed downward, and a strange craft began to descend to the middle of the field.

"All of a sudden, the band went dead."

I stood frozen at the window. I realized what I was seeing could be only one thing: a flying saucer, a space ship, one of those things from outer space that the long-hair weirdos are always seeing—a UFO in my back yard!

The craft settled down and all the lights except for a few directly facing me went out. The lights that remained gave off a bluish tint, so I was able to see the entire craft without difficulty. My best guess is that it was 75 to 100 feet wide and 30 to 40 feet high above the outrigger-type legs that were supporting the craft on the ground. All I could do was stare out the window wondering what the devil to do next.

I don't remember how long I stood there, but the receiver came back to life, and I made a quick stab at turning down the audio gain. When I looked out the window again, a section of the craft was being lowered to the ground and a set of stairs telescoped from the section to the ground. My heart was pounding so fast and I was so scared that I could do nothing but watch as two figures descended the steps and stood looking directly at me. The craft and two figures were only about 200 feet from where I stood, so I could see them clearly. They appeared to be of average human height, both rather slim and dressed in black gowns that fit close at the neck. Both figures had white hair that came down their faces as far as the eyebrows—what we call "bangs" on this planet.

Suddenly, both figures bowed from the waist in my direction. When they straightened up, one of them motioned for me to come toward him.

Hams From Another Planet

I'm sure some of you would have said at this point, "Don't go out there—not on your life. Stay put; call the cops. Call the Air Force. Call up all the prayers you know, pal, because you're going to need them, fast."

I did none of those things. Instead, I left the window, put on my hat and coat, went out the back door and walked up into the field toward the two figures, who were still at the foot of their craft. As I approached, I noticed both had normal faces and skin tone; in fact, one of them reminded me of an old buddy of mine. When I got within five feet of them, one of them spoke!

"Greetings. We mean you no harm. We come in peace. My name is Douga and he is Billo." The creature pointed to the other figure.

My mouth was so dry and I was shaking so much I could barely stammer, "How do you do?"

Douga, the one who had spoken, had a little star on the collar of his black robe. I took him to be the *numero uno* creature.

"We are from the planet Prado in the galaxy of Volar, and we have been monitoring your radio signals for some time now," said Douga. "We would like to talk with you and learn many of your customs, and perhaps you will tell us what these strange objects are and what they have to do with your radio signal." While Douga was talking, he pointed towards the Rohn tower with the 6-element Telerex and at the verticals and delta loops and slopers that populated my back yard.

"You mean the antennas?" I asked, sort of pointing to them all with a sweep of my arm.

"Antennas? Is that what they are called?"

LIMITED ANTENNA SPACE? B & W OFFERS SIX SOLUTIONS!

Barker & Williamson offers six new multiband trapped dipoles made to fit in less space than conventional antennas. You may not have room for that dream antenna farm, but no longer need limit your operating to one or two bands. These new antennas provide low SWR on **every** band making a great companion for today's solid state rigs.

140 Dog Branch Road, Brasstown, N.C. 28902

Billo reached down and removed a glowing object from his belt, pointed it at each of the antennas and them put it back on his belt.

"What was that for?" I asked.

"Don't be alarmed," he said, "I was only checking the radiation output. We are extremely interested in the design and size of these instruments."

Douga asked, "Would it be possible for us to look at your radio equipment? We are very interested in what you use to radiate such a strong signal. We have been monitoring your planet's signals for some time now and yours stands out as one of the strongest and most consistent."

Now I always feel pretty proud when some DX station gives me a 59, but when some creature from outer space tells me I have a big signal and wants to look over my antenna farm and rig, *that's* a compliment.

"Sure," I said, "come on into the house and I'll show you my rig." We walked towards the house, and when we got near the 100-foot Rohn with the tribander, Billo looked up at the beam, put his hand on his belt, and flew straight up in the air! He hovered around the level of the tribander and examined the elements. When I could talk, I said, "How the devil does he do that?"

"Anti-gravitational thrust," Douga replied calmly. "Do people on this planet use anti-gravitation?"

"I've never even heard of it," I told him, "but it would sure come in handy working on antennas." We reached the back door and went into the house and then into the radio shack. I don't have the best shack in the world, but I do have a TS-830, an L4B linear, an antenna coupler, a keyer, and a few pieces of 2-meter gear—not bad for an old-timer—plus a nice operating chair and a couch to grab a nap on now and then. All told, my shack is nothing to be ashamed of.

I remembered my manners. "Would you guys like a cup of tea?"

"I don't understand," said Douga.

"100 Watts into the Mark V at 14.2 MHz would radiate 1,420,000,000 Watts."

"It's a hot drink we enjoy on this planet. Would you like to try some?"

"Yes, thank you. May we examine your radiator?"

"Radiator! What's that?" I asked.

Douga pointed to the equipment.

"Sure," I said, "help yourself. I'll put water on for tea."

After I put the water on, I returned to the shack and found them both talking in a strange tongue. Billo was pointing the glowing belt-buckle at all my gear.

"Jim," said Douga in English, "how old is this equipment?"

I was taken back a little that he knew my name, since I hadn't given it to him. "How did you know my name?"

"As I said, we have been observing you for some time. Are you offended by my using it?"

"No, of course not."

"How much power do you radiate?" Billo asked.

I grew two feet taller as I gave the answer. "I can squeeze out 2 kilowatts on SSB and 1 kilowatt on CW."

"You use CW!" They looked at one another in amazement, then smiled. "Would you have the radiator path for this?" asked Douga.

"What's that? I don't understand 'radiator path.'"

"It's the electronic sequence of the equipment, or how it actually works."

I thought for a moment. "Do you mean the schematic?"

"Schematic? We do not know that term but perhaps if I could show you..." He pointed to the pencil and paper on the desk.

"Help yourself," I said.

Douga only had to draw a few lines before I knew what he wanted. He was drawing the output circuit showing a coil, capacitors, and some strange symbols I had never seen before. I opened the filing cabinet and took out the Kenwood manual for the 830, opened up

to the double-page schematic, and laid it on the table.

Billo immediately pointed his glowing buckle at it, and the two of them started chattering in that strange language again.

The tea kettle burst into song, so I headed for the kitchen while they were looking at the 830 schematic. When I returned with a tray and three cups of tea, we all sat down and I watched their faces as they tasted the tea. Both of them seemed to be delighted with the taste.

"What is this called?" Douga asked.

"It's tea. It comes from Asia. Do you know where that is?"

Both shook their heads. "Point to Asia," Billo said, indicating the Great Circle map on the wall.

I put my finger on India, and they both nodded their heads. "We know that part of your planet," Billo replied.

Douga pointed to the 830 and the L4B. "Is this the latest in your technology? What power do you run?"

"The exciter, the 830, puts out about 100 Watts, and the amplifier somewhere near 2 kW SSB." I got up the courage to ask the question that was *really* on my mind. "By the way, what are you two up to? It's not every day one gets visitors from another galaxy. Are you guys planning on taking over?"

"Oh, no" was the reply. "We are doing nothing but observing your culture and technological status and comparing them to ours."

"What have you found in regards to radio?" I asked.

"We hope you are not offended," Douga said politely, pointing to my rig. "This technology is 75 to 100 years behind ours."

"I don't understand," I said, "this is a late-model solid-state transceiver. It's the state of the art. What do you guys have that's so superior?"

Douga finished his tea, set the cup and saucer down, and looked and Billo, who nodded his head and smiled.

"Jim, your type of radio technology is based on the scientific principle that radio waves are generated in the transmitter section and then coupled into an antenna where they are radiated into space. If you remember the old theory of dropping a stone into a body of water and seeing the rings or circles spreading out from the point of entry, these rings spread outward to infinity and are supported or strengthened by additional rings caused by more stones being dropped into the water or some type of a wave generator."

"I know that theory, and it works. It's the basis for how radio signals go out from the antenna and are picked up all over the world," I replied.

"True, the old ones on our planet have recorded this type of radio technology, but that was many years ago. Have you no knowledge of ART?"

"ART? What's that?"

"It's Additive Radiation Technology, and it's the basis for our communication technology."

"Tell me more."

"Well, to put it into the simplest terms, when we radiate a radio signal with our equipment, the radiated waves, as they leave the antenna, are increased in intensity by the Herma action of the Wallo gate. In other words, as the signal is radiated into space, the speed of transmitted waves is varied so that one wave catches up with the preceding wave and makes it stronger. When all the waves reach the first wave, you have a tremendous signal going forward into space.

"This technology is 75 to 100 years behind ours."

"You must understand that the first wave generated travels at the speed of light, or 186,000 miles per second; in order for the succeeding generated waves to catch up to it, we vary the speed of the following waves up to one million miles per second so that each wave catches up with the one ahead of it and increases the master wave strength. Do you understand what I am saying?"

I really didn't know what the heck Douga was talking about but I wanted him to go on, so I said, "Oh, yes, I follow you."

He continued, "You can see that if a small amount of radio signal is generated, say on 30 MHz, you have 30 million cycles generated per second, and if every cycle adds to the strength of the first one, even by a small amount, the increase in signal strength is phenomenal. For example, let's take a generated signal of 1/1000 of a Watt at 30 MHz, okay?"

"I follow you, go on."

"If each following cycle, and there are 30 million of them, adds its 1/1000 of a Watt to the first cycles, you'll have 1/1000 x 30,000,000. In other words, a combined strength of 30,000 Watts has been added to the first cycle and that's what hits the receiving antenna. Of course, this is not possible without the action of the Wallo gate, which increases the wave speed in such a ratio that all 30,000,000 cycles catch up to the first generated wave."

"How long have you guys had this kind of equipment?" I asked.

"For at least 75 years," Billo said.

"Jim, there is something else you should know about the signal," said Douga. "Once you select a frequency, say 21.250 MHz, and start to transmit, the Hallis discriminator imposes an absorber that is attached to your frequency and destroys all other signals that come anywhere near 21.250 MHz. This means that no other signal can come within 5 kHz or it will be totally absorbed and dissipated by the action of the Hallis."

59 Plus

"Let me get this straight," I said. "Are you guys saying you have a radio that takes a 1/1000 of a Watt radio signal and boosts it up to say 30,000 Watts out in space, and then by some means prevents any other signal from coming closer than 5 kHz to it?"

Yes, that's the basic performance of our radio technology," replied Douga.

"Have you got one of those radios on that craft out there?"

"Yes, we have. Would you like to see it?" asked Billo.

"God, would I!"

Douga said something to Billo in that funny language of theirs, and Billo left the room. When he came into the shack, he had a small box about the size of a Drake TR4 in his arms. He placed the box on my operating table. I could see it had three or four dials on the front with four or five knobs and a tube-like device sticking out of the back.

"Let me show you how this works," said Douga. He reached down and snapped on a switch and a window lit up showing a digital display and readout of 9,500 GHz. Douga touched another button and the display stopped at 14.175 MHz.

"May I attach your antenna to this?" he asked.

I disconnected a PL-259 from the B/W switch and passed him the coax, the other end of which was connected to the 6-element Telerex up 110 feet in the air.

"I should mention," said Douga, "that the receiver signal goes through the same process as the transmitted signal; in other words, it is amplified—in this case, 14,175,000 times—via the reverse Wallo gate action."

"Of course," I nodded.

Douga stuck the PL-259 coax connector somewhere into the back of the box and turned on another switch. Audio came forth from the box. It took a few minutes to figure out who was talking to whom on 14.175 MHz, but whoever it was had a 5-9 plus signal and was in the clear. The guy signed. It was KH5ZZ on Palmyra signing with a W6.

"Who is he?" asked Billo.

I explained that Palmyra was an island in the Pacific and that it was a long ways off and good DX.

I pointed towards the box,"Is there any way I can use that thing to talk to that KH5?"

"Oh, yes, it's very easy. All we need to do is plug in the mike."

I passed him the D104, and he plugged it in and passed me the mike. "Go ahead, call him," he said.

"KH5ZZ, KH5ZZ, this is W1ROM, do you copy?"

"W1ROM, this is KH5ZZ. Good morning, old man, you have the strongest signal I have ever heard from the states. In fact, you have pegged my S-meter. Are you really a W1? W1ROM from KH5ZZ."

I went back and to the KH5 and assured him I was a W1 and gave him a line of talk like conditions were super between us and there was a window opened between us. I couldn't tell the guy what was really going on; he would have though I was off resonance.

"My God," I said to the two guys with me, "this is great. I would love to have this thing for a while."

Douga looked at Billo for a moment, then he said, "It's yours, Jim. You may have it for one year, and then we will return and visit you again."

"You're kidding!"

"No. It's yours. Let us show you a few more operating points." They went on to explain that the output of the 830 could be connected into the Starbeam Mark V, as they called it, and explained that whatever was put in, depending on the power and frequency, the results would be the power times the cycles per second and that reasonable caution should be exercised. They went on to say that, for example, if I put 100 Watts into the Mark V at 14.200 MHz, I would radiate 100 x 14,200,000 or 1,420,000,000 Watts on that frequency only. They cautioned that this amount of power could burn out most radio receivers.

I asked where the power cord was, and they said the radio had an internal atomic power source that would last for at least 1,000,000 operating hours.

"We ask two things in return, Jim," said Douga.

"Name them," I said.

"We want to hold a monthly meeting with you on 9,555 GHz. You can do this by dialing up the frequency like this, and you can use any antenna because the circuit in the Mark V will automatically adjust for any antenna."

They suggested the last Sunday in each month at 2315Z. If anybody out there has a receiver that goes to 9,555 GHz, you might hear us some Sunday night.

"What's the other thing?" I asked.

Douga looked a Billo and then back to me. "We would like to take some of your tea back to Prado."

"You got it." I went into the kitchen, dumped what tea was left in the jar, and took a full pound out of the closet. I put them together in one bag and went back to the shack, where I passed the bag to Douga.

"Thank you, Jim. Our visit has been a pleasure."

"The pleasure is all mine, old buddy," I replied.

"Old buddy?" said Billo. "Are you a CBer?"

"CBer? Oh, no! I want no part of that outfit."

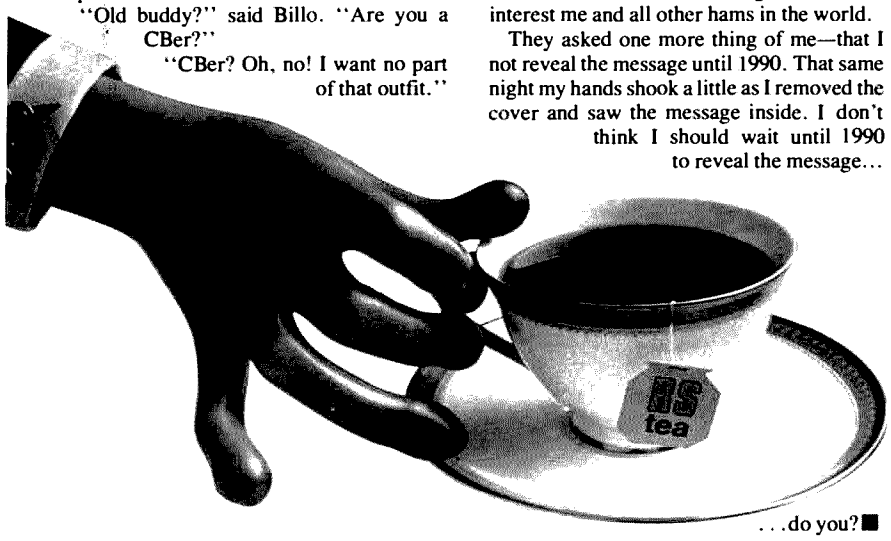
"We listen to them now and then and have decided there is not much in their technology that would interest us. It's time we were leaving, Jim," said Douga. "We appreciate your hospitality, your tea, and your explanation of your fine rig here."

"We'll see you again," added Billo.

We all shook hands after I explained that this was a custom on Earth between friends. I walked out to the craft with them, and as they entered, Douga looked back and said, "Remember our schedule now, every last Sunday of the month."

"I won't forget. See you later, fellas."

Douga looked down at me for a moment. "73s," he said and smiled. "I know there is no 's' on it, Jim, but take care." He entered the craft, the stairs went up, and the door closed. A row of lights came on and a humming sound became more intense. I moved back away from the craft as it started to rise gradually, picking up speed. In a few moments it was out of sight.



News for Hams Everywhere

I came back into the house and into the shack. The black box was still there, but for some reason I didn't expect it to be. It was now close to 5 a.m., so I went back to bed. At 6:30, the XYL woke me, and I dressed for breakfast and got ready for work. She mentioned that she hadn't slept well and had crazy dreams about strange people out in the back yard.

Three months have gone by since that memorable night. During that time I connected the Starbeam into the 830, and you can imagine the results. I call any DX station I hear, once, and I am QRP into the Starbeam. I always get 59 plus, and I have worked all countries on all bands. It has gotten so it isn't fun any more, except for the last Sunday in every month, of course.

During contact one Sunday not too long ago, I was saddened to hear from Douga and Billo that they had decided not to return to Earth for reasons they couldn't explain to me at the time. They said that the Starbeam was mine to keep, and that if I removed the top cover I would find a message that would interest me and all other hams in the world.

They asked one more thing of me—that I not reveal the message until 1990. That same night my hands shook a little as I removed the cover and saw the message inside. I don't think I should wait until 1990 to reveal the message...

...do you? ■

The Hula Hoop Loop Revisited

Looking for relief from power-line noise? Visit your local toy shop!

Are you plagued by power-line noise on the low bands? Bothered by noise from an unknown source? There is a solution that requires no special tools or hard-to-find materials, one that could solve or greatly reduce this noise and provide you with a better signal-to-noise ratio—it's a loop antenna with an innovative twist.

Loop Antennas

Loop antennas are already familiar to many people; they've been used for direction finding on-board ships and in land stations for many years. Their construction has always been rather complex, involving the use of copper tubing as an electrostatic shield. Coax has also been used with fair results [1,2,3]. Previous emphasis has been on obtaining a figure-eight pattern using two nulls, a method that requires electrostatic shielding. Shielding the loop also helps reduce rain static noise. In short, for direction finding where you need a good null and the null direction must be accurate, shielding is a definite requirement. In terms of noise elimination, a single null is preferable; you want to eliminate interference from one direction but not reduce the signals from other directions.

Drawing on my past experience of building loop antennas for 160m before World War II (I used bicycle-wheel rims—they were wooden in those days—to support the loop wires), I began looking for an easy way to again do the same thing. It came to me that a toy called the Hula Hoop might be the answer. I purchased two Hula Hoops; one antenna I constructed with an electrostatic shield and the other without.

I made the shield by wrapping aluminum foil—the type used to repair rain gutters—around the Hula Hoop, leaving a gap at the top to prevent short-circuiting the received signal. It was a difficult task, and the final appearance wasn't very professional. When I was finished, I compared the two loops to see how well they rejected power-line noise. The rejection was about the same, but signals were slightly weaker on the shielded loop.

Because it looked better and gave a slightly better performance, I decided to go with the unshielded loop. Although it wasn't intentionally designed to give a single null, the receiving pattern turned out to be just that. This was probably due to the unbalanced coaxial feedline.

I obtained the cardioid pattern (Fig. 1) from a local broadcast station (daytime) on the upper end of the band. Although the null is quite good, I can't guarantee the accuracy of the null direction. This makes no difference if you are just trying to null a noise source.

When the project was finished, I decided to see if any articles had been written already on the subject. Sure enough, I found at least one—there may be more. W5DS wrote an article for *QST* that was published during the last sunspot minimum.[4] This article describes using a Hula Hoop and even the same aluminum foil that I used. Foiled again...but then again, I decided not to use the foil. In addition, due to its internal construction, the W5DS loop's receiving pattern was the familiar figure eight. Because the essential Hula Hoop idea has already been presented, we'll have to call this project "The Hula Hoop Loop Revisited."

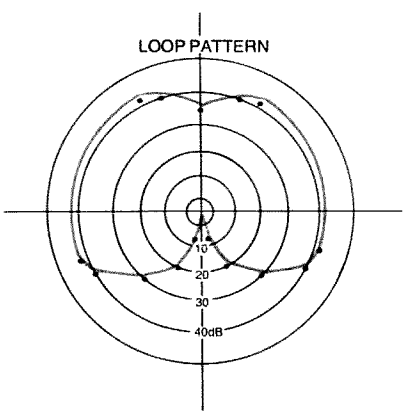

Fig. 1. The Hula Hoop Loop's receive pattern.

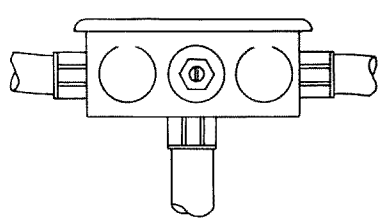

Fig. 2. PVC adapters and a breakout box make for easy mounting.

Construction

Hula Hoops are readily available in toy stores. The latest fad is to make them look like peppermint candy—they even put peppermint candy inside the hoop to give the proper smell!

To find the place where the loop is fastened together, remove the label; you'll find small staples that can easily be pried out with a sharp pick. The hoop core diameter is about the right size to fit into a PVC ½-inch end adapter. These have threads on one end and a body for the loop to fit into on the other. Using PVC cement, glue one of these adapters on each end of the hoop (Fig. 2). While you wait for it to dry, prepare a single gang electrical "handy box" normally used for wall switches by removing the two end knockouts plus one on the bottom. You must also mount a tuning capacitor in the box. It should have a value of about 300 pF for the 160m band. You can use an Arco 303 (65-365-pF) padding capacitor if you find one in your junk box, or use a tuning capacitor from an old pocket transistor radio. If neither of those is available, Circuit Specialists in Ari-

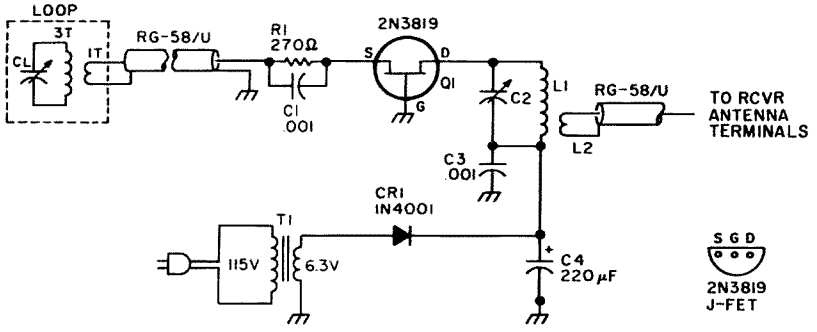

Fig. 3. This preamplifier boosts the signals back to a reasonable level. It's a simple circuit using a FET in a grounded-gate circuit that gives about 20 dB of signal gain.

zona has tuning capacitors in its catalog.[5] Naturally, the size of the hole for mounting the capacitor depends on the type.

The loop is now ready to be mounted into the box. Insert the ends into the box and secure the adapters with ½-inch locknuts of the type used for electrical conduit installations. Before locking tight, orient the hoop so it's at right angles to the box top. Once that's together, it's time to feed in the wire.

Internal Wiring

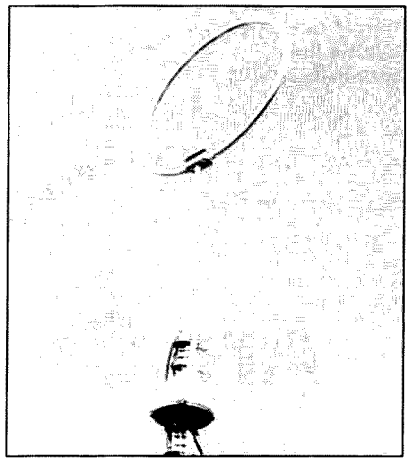
The wire used for the loop should be flexible but still stiff enough so that it won't buckle when pushed around the loop. (I used #18 AWG multi-stranded insulated wire.) If necessary, you can use a stiffer piece of wire as a fish line to pull each loop through. To prepare the wire for the loop, cut a 30-foot length and slowly start to feed it into the hoop. After the wire has been passed around three times, tape the ends temporarily to the outside of the Hula Hoop. Next, pass around another single turn of wire 10-feet in length, creating a one-turn loop. The one-turn loop will be connected to the coax. Now mount the capacitor and connect the ends of the three-turn loop to the rotor and stator. Make sure that the rotor is not grounded to the box; if it is, you'll have to insulate the shaft.

Before the coax is connected, the mast that will support the loop must be mounted. (The mast should not be metallic—a length of heavy-duty PVC can be used for this purpose.) If you do use PVC, I suggest a length no longer than 3 feet. You can use metal pipe only if there is an insulating section between it and the handy box. I've found these precautions improve the depth of the null.

Secure the mast in the same fashion as the hoop with an end adapter and locknut. Feed the coax up through the bottom of the mast or through a hole in the side of it. Pass the coax up the mast until it reaches the box. Here, connect the shield and inner conductor to the one-turn loop. Be sure that the coax doesn't short out against the box. Use tape or shrink tubing to prevent this from happening. You can now mount a blank handy-box cover to the top of the box to complete the assembly.

After you check out the loop, it's wise to seal the cover and any openings with silicone adhesive.

Adjustment and Operation



The antenna can now be connected to a receiver input for preliminary adjustments. Select the frequency you use most often and, if the noise source is available, point the loop to give maximum signal and adjust the capacitor to give maximum noise. (I did my preliminary adjustment with the loop in the shack; otherwise, it takes two people to make this adjustment.) Once adjusted, rotate the loop to give minimum noise. The loop should be approximately at right angles to the maximum position. Rotate the loop 180 degrees and only a small dip will be found.

"Signals that were unreadable because of the power-line noise are Q5 with the loop."

You'll immediately notice that the signals on the loop are weaker than on the regular receiving antenna, but the signal-to-noise ratio should be greatly improved. The bandwidth of the loop is about 60 kHz, and it will receive signals across the entire 160-meter band.

Preamplifier

In order to boost the signals back up to a reasonable level, I constructed a pre- amplifier (Fig. 3). It's a simple circuit using a FET in a grounded-gate circuit that gives about 20 dB of signal gain. The preamplifier is built in a metal box to prevent stray pickup, and it includes the power supply. I used coax fittings to bring in and take out the signal. The capacitor is the same type used for the loop and is peaked for maximum signal. It can also be stagger-tuned with the resonant frequency to give a broader bandwidth.

If you suffer from power-line noise, the solution to your problem may lie in a simple Hula Hoop.

Using the loop, I have found that signals that were unreadable because of the power-line noise are Q5 with the loop. The loop directivity has little or no effect on sky-wave signals and therefore can be set on the noise source and left there, providing the noise is always from the same direction. This project should cost less than $15, including the preamp. It's simple enough that no one should have difficulty in its construction. Although I haven't tried it, you should also be able to use the loop on 75 with fewer turns; since there is ample room, it can possibly work on 160 kHz with additional turns.

By the way, the power company has since replaced the transformer that was causing my noise problem, but there is still some residual noise, which is easily nulled out. ■

Are Sine Waves Sacred?

W6HDM thinks not and gives a convincing argument for abandoning 60-Hz ac.

Our perceptions of the world around us, naturally enough, can lead us to the assumption that *other* formats, *other* procedures, and *other* viewpoints than ours can justifiably be relegated to oblivion, deserving no further consideration. Take that nice sine wave pictured in Fig. 1(a) that the utility endeavors to pipe into our home or workplace. Since Edison's pioneering work in power generation and distribution, virtually no further protest has been heard against the use of sine waves or ac in general. Of course, Edison—not withstanding his brilliant record as an inventor—committed the intellectual faux pas of rejecting ac altogether; he didn't understand the mathematics involved.

It has been about a century since Edison's desire for dc was overruled, and the world has become crisscrossed by a vast network of ac power lines. Would one dare suggest, at this late date, that some *other* waveform than the sinusoid might be more suitable for the transmission, distribution, and consumption of electric power? Such, indeed, is the gist of this article, and the reader is invited to judge whether such a suggestion smacks of boldness or recklessness—or perhaps of something in between.

At the very outset, remember that whatever beauty the sine wave was endowed with at the generator is generally conspicuous by its absence by the time it gets to your wall socket. In many cases, it is likely to resemble the harmonic- and transient-ridden wave depicted in Fig. 1(b). This comes about via thousands of SCRs and other solid-state power devices, motors, nonlinear loads, reactance, arcs, sparks and faulty contacts, storm-induced currents, etc. The idealized sine wave of the textbooks, with only its fundamental frequency and no transients or noise, is *not* what we plug into.

This situation is food for thought—if such a messed-up *former* sine wave is what we usually get in actual practice, it might indeed be advantageous to start out with some *other* waveform. Even assuming that another type of wave would also be subject to the brutalities inflicted on the sine wave, the overall situation resulting just might exhibit some desirable features! And if the vested interests in the status quo are too strong for a change in the way our large cities are powered, maybe our new waveform can still give a good account of itself in isolated communities, on shipboard, or in space vehicles.

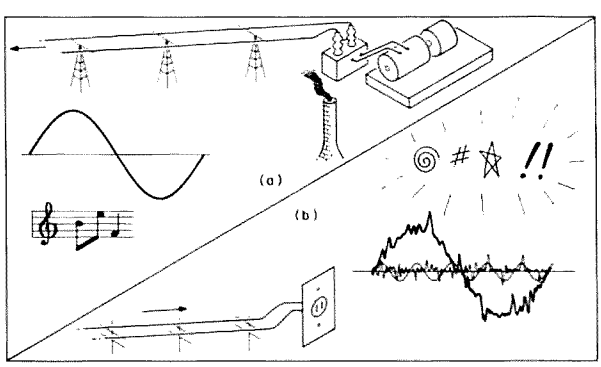

Fig. 1. The sine wave from the utility is esthetically pristine and electrically "pure," but alas, corruption has set in by the time the power reaches our wall socket.

Admittedly, fantasy can ensue from that kind of thinking. It will prove profitable, however, to bear in mind that imaginary scenarios often are invested with more than a mere modicum of truth. We knew all the time, did we not, that Dick Tracy's wrist transceiver was just around the corner? And did not the space weapons of Buck Rogers make sense just because we sensed their imminent appearance?

The nature of the fantasy in which we will immerse ourselves here is simply the pretense that Thomas Edison mostly *did* get his way and that most of present-day electric-power transmission and distribution *is* dc and not ac. (Surely, you will recall that Edison did not like ac because volts, Amps, and Watts often did not add up properly in a distribution system when tallied with common sense arithmetic; and there were others accomplished in the electrical technology of the day who also frowned upon the violation of Ohm's "law" in ac circuits.)

So, here we are. It is 1986, and (we pretend) dc is the fashion of the day. There is, however, much ferment and controversy because several of the more progressive utilities have wired up isolated towns and communities with ac distribution! They have demonstrated beyond reasonable doubt that ac systems are much more flexible and versatile—thanks to the use of transformers—than dc systems! Moreover, by using 60-Hz sine-wave generation, they have shown the path to greatly-upgraded industrial processes via the induction motor!

Whether formulated in so many words or not, the burning question in our pretend world is: What shall be the future format of electric power distribution, ac or dc? And if ac, what frequency and waveform? It is universally conceded that 60-Hz sine waves make much sense, but there are contenders and lobbies for other ac parameters, too.

In particular, a think tank formed by a group of overaged, unemployed engineers has advanced compelling arguments for a standardized generation and distribution format using 100-Hz near-square or trapezoidal waves. Inasmuch as some of these industry-rejects are hams, it would behoove us to give

their theories due consideration (even if they are seemingly on the wild side). In so doing, we will at least be acting more wisely than our corporations, which relegate engineers to the scrap heap when the blush of youth fades from their cheeks.

Trapezoids

A *trapezoidal* waveform is advocated as being invested with a good blend of theoretical and practical pluses. Fig. 2 depicts such a wave, and shows it to be composed of the fundamental frequency plus two harmonics, 3f and 5f. This, of course, is old hat to those of us acquainted with the Fourier theorum of wave composition. (An interesting aside is that the fundamental frequency has greater amplitude than the composite trapezoidal wave; this is not a draftsman's boo-boo and will be dealt with later.)

Right off the bat, our curiosity is aroused with regard to the trapezoidal waveform. If one is to go in this direction—toward harmonic-rich waves—why not just select a nice 50%-duty-cycle *square* wave and be done with it? In answer to this very natural question, the august body of practical scientists of the think tank replies that the square wave was, indeed, their first consideration. It was, however, quickly and clearly evident that true square waves, or even "practical" square waves, were possessed of two overwhelming disadvantages. First, it would be impractical to try to generate, transmit, and distribute square waves because reactive loads and stray reactances would play havoc with the high-frequency components of such waves, thereby distorting their shape in unpredictable ways. Second, square waves, as is shown in Fig. 3(a), contain numerous high-frequency harmonics which would create interference with radio, TV, and with communications systems in general.

Assuming that the square wave would be otherwise still worthy of consideration, Fig. 3 also confirms something of relevancy. This is that a near-square wave can be formed from just a few harmonics. Thus, in Fig. 3(b) we see a trapezoidal wave essentially made up of four harmonics, 3f, 5f, 7f, and 9f. Instead of many hundreds or many thousands of higher frequency components, this waveform can be tailored to carry no more than four or so. It can be appreciated that if we allowed, say, ten harmonics, the waveform for certain practical purposes would be square but without power to create radio and communications interference. This, it is contended, is a fortuitous phenomenon inasmuch as steep-rise and -fall square waves are not practical to distribute and feed to loads anyway. It is true that nothing yet has been cited to justify consideration for such a compromise square wave. Accordingly, let's see what the behavior of such a waveform might be and how it stacks up with the sine wave. (And most important, let's make the comparison in terms of things which exist in actual practice.)

New Waveform Needs

A natural question is, why the sudden interest in square-wave power? Why bring up a non-sinusoidal waveshape now? After all, practical electrical technology has been more than three quarters of a century in the making. Surely the virtues of other than sine waves would not have escaped consideration during this long evolutionary period.

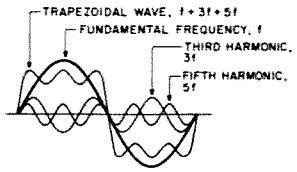

Fig. 2. Trapezoidal wave composed of just three frequencies. The Fourier theorem of wave composition states that any wave may be resolved into a fundamental frequency and a number of harmonic frequencies with appropriate phase and amplitude relationships.

Indeed, the knowledge was there, even at the turn of the century. However, two things were lacking until relatively recently. First, the need for a better waveshape did not manifest itself for a long time. As long as the primary type of load was incandescent lighting and the user of electric power received a fairly good sine wave, no case could be made for another waveform. Second, the processing equipment for forming and transmitting near-square waves evolved with the advent of semiconductor power devices, especially the SCR. Previous methods for doing this were neither economically nor technologically suitable. Also, earlier core materials would have exhibited objectionable losses if subjected to low audio frequencies residing in a trapezoidal wave. Today, however, transformers are both feasible and cost-effective for manipulating 100-Hz trapezoidal-wave power.

Admittedly, if your utility suddenly switched over to 100-Hz trapezoidal power, there would be some difficulties, perhaps even some malpractice suits! For one thing, electric clocks would run too fast, by the ratio of 100:60. So, too, would all 60-Hz induction motors. (This might cause your washing machine or dishwasher to work better than ever, but I will not belabor this point!) Note, however, that the motors overspeed because of the postulated 100-Hz line frequency, *not* because of the new waveshape.

This gets us into an interesting topic—the behavior of motors on non-sinusoidal waves. Fortunately, a good deal of practical experience has been accrued in this area because of the electronic generation of square waves. The simple saturable-core, two-transistor inverter is a classical example of a square-wave power source. Also, SCRs have been much used in higher-power versions. There is much interest right now in motor operation from inverters because of solar- and wind-powered units for homes (as shown in Fig. 4). Here, again, we find ourselves in a situation which did not exist to any great extent until the commercialization of solid-state power devices.

There are several reasons why 100 rather than 60 Hz is suggested for trapezoidal-wave power. Many feel that 60 Hz is marginal with respect to eye fatigue from flicker. This is especially true for fluorescent illumination—ask any draftsman! 100 Hz would blend in nicely with the metric system. And, with 100-Hz distribution systems, worthwhile savings would be realized in the size and cost of transformers.

Waveform Character

Although most of us are vague as to where or when we absorbed the information, we know that the peak value of the sine wave is not very useful beyond its capacity to break down insulation. (A couple of exceptions are in the development of high voltage in voltage-multiplying rectifier circuits and in the turn-on impulse of fluorescent lamps.) What generally gets the job done in electrical loads is the rms value of the sine wave, and this is only approximately 70% of the peak value. In motors and in other electromagnetic devices, usefulness of the peak is even less because it is the average value that does the work. The average value of the sine wave is only about 64% of the peak value. In sharp contrast, the peak, rms, and average values of a square wave are the same! For practical purposes, this remains true for a trapezoidal wave with about seven or more harmonics.

It is easy enough to see that the trapezoidal wave has some of the desirable features of square waves, and without the interference-prone higher harmonics. And it certainly is going to be kinder to transformer and motor insulation, to rectifiers, and to filter capacitors than sine waves! Also, certain instrumentation and computations could be less confusing with trapezoidal than with sine waves.

The close resemblance to, and the easy derivation from square waves suggests that the low-level manipulation of trapezoidal waves can be accomplished readily with digital-logic circuitry. Such manipulation can include power-factor correction and the generation of polyphase formats. These and other techniques stem from the precision of logic circuits in timing applications.

One reason that the trapezoidal wave tends to be benign to apparatus originally intended for sine-wave operation is that these waveforms are not drastically different in their composition; neither has any dc component or even-harmonic energy; actually, the harmonic constituency of the "wall-socket" sine wave and the limited-harmonic trapezoidal wave can be surprisingly similar. By appropriately tailoring the amplitudes and phases of some wall-socket sine waves, you could form a trapezoidal-like waveform. (In other words, what started out as a pure sine wave reaches us quite distorted with third, fifth, and higher harmonics.) From the use of solid-state inverters, we know that many kinds of electrical loads have been successfully operated from square waves. It would be natural to anticipate even better results from trapezoidal-wave power.

Note from Fig. 2 that the sine-wave component of a square or trapezoidal wave actual-

ly has a higher peak value than the composite wave itself. This, of course, is not visible on an oscilloscope, which shows only the *envelope* of the composite wave. One must perform a Fourier analysis or plot the graphical composition of the harmonics to appreciate this.

Now, it appears that because the peak of the sine-wave fundamental is considerably greater than that of the composite square wave, the rms value of the sine wave is greater than that of the composite square wave. This, however, is not so. Actually, it turns out that the rms value of the fundamental sine wave is about ten percent *less* than the rms value of the composite square wave of which it is a part. What this means is that a square wave should have an rms value ten percent *greater* than the rated rms sine-wave voltage stamped on the nameplate of the motor.

Although no mathematics was used in arriving at this conclusion, it naturally follows from the Fourier theorem and from the relationships of peak and rms voltages in waveforms. It is well known, however, that inverters used for driving motors often do not impress 110% of rated sine-wave voltage on the motor; indeed, it is more like 90% in practice. The reason for this is that many motors would develop excessive temperature rise from a 110% square wave due to increased losses from eddy currents and hysteresis. For, even though the inductance of the motor or of an external inductor strips higher harmonics from the current waveform, these harmonics in the voltage waveform still can cause added dissipation in the motor. It is not difficult to design the motor to minimize such losses, but as we know, most 60-Hz motors were not envisaged for use with a square-wave source.

When the driving voltage has the nature of the trapezoidal waveform advocated, it is found that motor losses are less than when operating from a square-wave source. Accordingly, it will be found that 100% of the sine-wave rated voltage can be applied. (Incidentally, many of the "true" rms digital multimeters are just what the doctor ordered for measuring the rms value of low-frequency trapezoidal waves!)

Recapitulating, ac motors driven from a trapezoidal-wave source tend to develop near-optimum performance. This is because either self-inductance or external inductance causes the torque-developing motor current to be nearly sinusoidal, and because the trapezoidal voltage waveform is devoid of the higher harmonics present in a square wave. It is, of course, true that the strong third, fifth, and seventh harmonics in a trapezoidal wave still can degrade the efficiency of the motor; practical experience seems to indicate that most 60-Hz motors don't fare too badly.

Interference

It is common knowledge that a pure sine wave contains no harmonic frequencies above the fundamental and is, therefore, unlikely to interfere with radio-frequency systems. It is also recognized that the ideal square wave is capable of providing a spectrum of harmonic frequencies covering all communications services from low-frequency systems to millimeter equipment. Indeed, even the ordinarily-encountered, "practical" square waves, such as are produced in switching power supplies, can blanket many communications bands with severe noise interference. This suggests that sine waves are the good guys and square waves are the bad guys. However, it has been pointed out already that the nice sine wave is a textbook entity not too often encountered at the wall socket. The distortions that characterize the voltage and current waveforms of utility power as well as the transients and noise that come along for the ride create numerous problems in communications gear and in computer equipment.

Inasmuch as the practical sine wave has tarnished credentials and the practical square wave never had any, the trapezoidal wave with a few allowed harmonics begins to appear in a more favorable light. It remains to be shown that such a wave is at least as satisfactory as the sine wave for power purposes. To be sure, it will also be messed up at the wall socket. However, such a wave might be easier to clean up than a transient-laden sine wave. This is because its nearly flat top would allow more effective use of transient-clipping devices such as back-to-back zeners, MOVs, or similar devices. Interesting, too, is the fact that a little rudimentary filtering imparted to a trapezoidal wave readily yields a near sine wave of better quality than we are accustomed to monitor now at our wall sockets!

Electric Shock Hazard

Tissue damage and heart fibrillation are very much a product of the amount of current passing through the body. At moderate voltages—those likely to be encountered at home or at work, i.e., 120 or 240 volts—the initial contact resistance of the skin figures predominantly as the current-limiting mechanism in most accidental contacts with the power line. If you are destined to be shocked by a 120-volt line, it would be better, other things being equal, to be subjected to a trapezoidal wave than a sine wave. The reason is that the peak voltage of the sine-wave line is about 170 volts compared to the approximately 120 volts of the trapezoidal line. It is likely that 170 volts will establish a lower resistance contact with the skin than 120 volts, at least during brief accidental shocks. Although we are in a somewhat controversial area here, it does appear that the high peak of the sine wave increases the danger from a momentary shock.

Corona

A considerable power loss occurs in high-voltage transmission lines due to ionization of the air, or corona. Among other parameters,

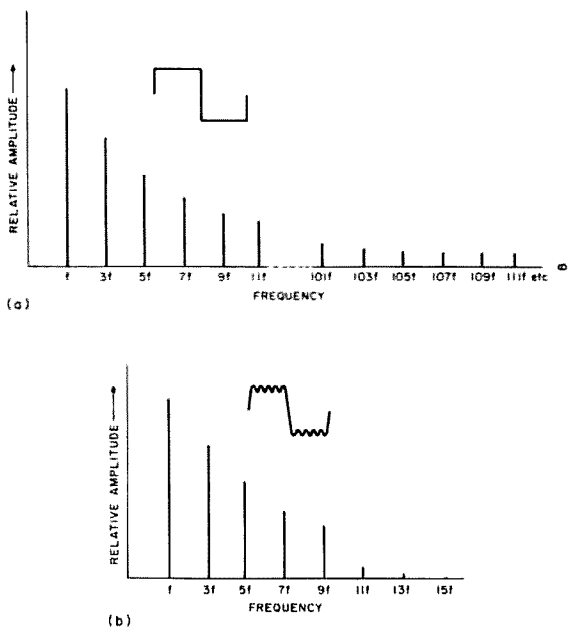

Fig. 3. The harmonic spectra of square and trapezoidal waves. (a) Harmonics in a square wave—the harmonic frequencies go on forever (or almost). (b) Harmonics in a trapezoidal wave—a limited number of harmonics suffices.

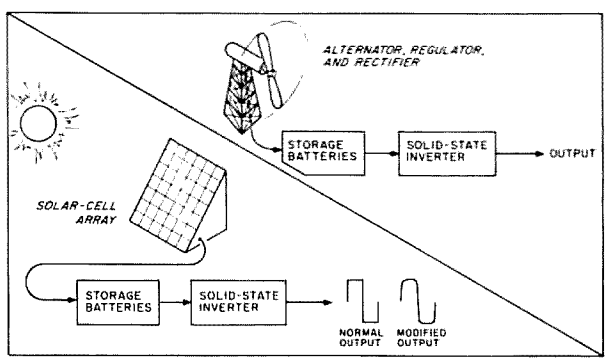

Fig. 4. Trapezoidal waves are readily obtainable from alternate-energy systems. The square-wave output from inverters is easily modified into the more benign trapezoidal shape.

corona loss is a function of voltage. Inasmuch as the peak voltage of a sine wave is about 40% higher than that of a trapezoidal wave having the same rms voltage, it would appear that more efficient transmission of electric power could be expected with the trapezoidal than with the sine wave. At the same time, QRM from the corona should also show a worthwhile reduction. A similar argument prevails for the sparking and arcing across leakage paths of high-voltage insulators: the less peak voltage, the better.

Fluorescent Lamps

Both the use of the trapezoidal wave and an increase in frequency to 100 Hz would tend to produce a steadier light from fluorescent lamps. Some fluorescent-lamp circuits that now operate from 60-Hz sine-wave power probably would not start if nothing else were done but changing the power-line format to a trapezoidal wave. This is because sufficient peak voltage would not be available during the start phase of operation. Various strategems could be used to circumvent or overcome this malfunction, however. Manufacturers would likely market a special ballast inductor or transformer for the purpose. A number of purely electronic techniques might also be employed in which a momentary transient of high voltage could be developed. In any event, the design of new or replacement fixtures for accomplishing the purpose would not present any severe technical or cost problems. And once trapezoidal-wave power became fairly commonplace, there is little doubt that the fluorescent lamps themselves would be optimized for reliable starting at the lower peak voltage associated with the new waveform.

Trapezoids and Dc Power

A wide spectrum of electronic equipment makes use of power supplies which rectify and filter the ac from the utility. For a long time, virtually all such supplies used an isolation or power transformer. In any event, such transformers operate just about as well from a trapezoidal wave as from a sine wave, although the mathematics of design would not be quite the same if one decided to dedicate the transformer for a specific waveform. Although square waves would introduce some problems, the trapezoidal wave can be expected to be completely acceptable to transformers, especially if any reasonable safety factor was incorporated in the original design. The design of new transformers to accommodate the trapezoidal waveform certainly would present no problems.

The rectifier elements would be spared the necessity of being rated to withstand peak voltages appreciably higher than average or rms, as is the case with sine waves. The rectifier elements "see" the envelope of the trapezoidal wave, just as on the oscilloscope. This is fortuitous because the rms, average, and peak voltage in a trapezoidal wave are nearly identical.

Note that the high peak of the fundamental component as shown in Fig. 2 is not experienced by the rectifier elements. As previously stated, only the envelope of the composite wave manifests itself insofar as peak voltages are concerned. Although this may be of small consequence in low-power equipment, it has very favorable electrical and economic significance in the design of high-voltage power supplies which are called upon to provide appreciable power as well.

Another advantage of the trapezoidal wave is in the residual ripple following rectification. Simply stated, less filtering is needed than for sine-wave operation of the supply. And, unlike square-wave operation, there is much less trouble with electrolytic capacitors that do not function well at high-ripple frequencies. Similarly, because there is almost negligible harmonic energy at high-ripple frequencies, filter chokes can do their job without being bypassed for high frequencies by stray capacitance.

It may be argued that some supplies, such as voltage multipliers which depend upon peak voltages to develop their high voltage, would not deliver expected voltage. This contention is valid for no load or for very light load. But if any appreciable current is required, the improved regulation which will result with the trapezoidal wave would be a compelling feature (see Fig. 5). Regulation is improved because there is less "dead time" between rectified pulses.

All things considered, my proposed trapezoidal wave should be very kind to electronic power supplies!

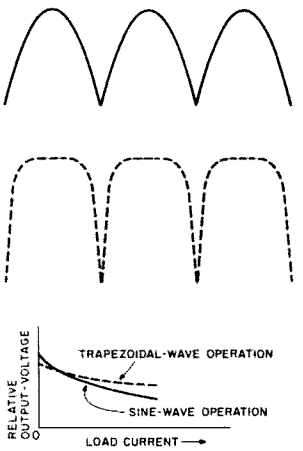

Fig. 5. Dc power-supply behavior for sine and trapezoidal waveforms. Top: full-wave rectification with a sine-wave. Center: full-wave rectification with a trapezoidal wave. Filter capacitors have more time to charge and are allowed less time to discharge. Bottom: general form of regulation curves. Note higher light-load voltage for sine-wave operation—this might be of significance in certain applications of voltage-multiplier circuits. For most applications, the better regulation of the trapezoidal-wave operation would be considered advantageous.

Trapezoids and Electric Motors

Square-wave operation of motors is a mixed bag. On the one hand, induction and synchronous motors don't like the square waveform; the harmonics therein contain increased eddy-current and hysteresis losses. These harmonics often develop countertorques that interfere with smooth operation and sometimes inhibit self-starting. However, the self-inductance of such motors often comes to the rescue by attenuating much of the harmonic energy, thereby making the waveform of the motor *current* near-sinusoidal, or approximately trapezoidal. Whether or not adverse operation will be experienced depends to a great extent upon the design and construction of the motor. If the self-inductance is relatively high and if thin laminations of quality-grade motor steel are used, the motor is very likely to start and run normally. Also, it is generally feasible to insert a small inductance in series with the motor to provide the small amount of filtering needed for satisfactory performance. In any

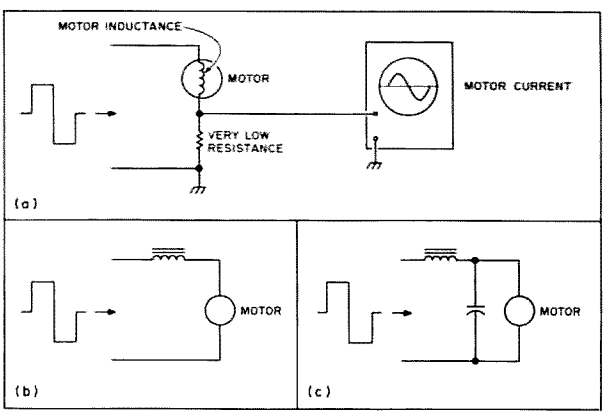

Fig. 6. The rationale for trapezoidal-wave operation of ac motors. (a) Setup for monitoring motor current reveals that it tends to be trapezoidal even though square-wave voltage is applied to motor. (b) Instead of relying upon motor inductance to strip higher harmonics from the square wave, a small external inductor can be used. (c) For small ac motors, an L-section low-pass filter can be a cost-effective way of ensuring that the motor actually "sees" a near-sinusoidal or trapezoidal wave.

event, it is motor *current* that produces the turning torque, not motor voltage.

If, however, we start out with a trapezoidal wave, the chances are enhanced that most motors will behave well. The third and fifth harmonics of such a wave many still interfere with certain small motors, but here again a small inductance connected in the line tends to alleviate trouble. Moreover, with small motors it is cost-effective to use an L- or pi-section low-pass filter in the line for even better attenuation of harmonic energy.

Series motors, otherwise known as universal or ac-dc motors, also run well from square waves and may even develop improved torque characteristics. Sometimes, depending upon a number of motor-design features, commutation problems may be experienced in the form of excessive sparking. This can usually be remedied by connecting a capacitor across the armature. Here again, less trouble is likely if one starts out with a trapezoidal rather than a good square wave. Added insight into these matters is provided by Fig. 6.

The situation with regard to the voltage that should be applied to a motor operating from non-sinusoidal power has already been alluded to. Additional insight is readily attained by consideration of the nature of the good square wave. One then can closely approximate the situation prevailing for the near square wave or trapezoidal wave. Recall that the rms, average, and peak values of the square wave are one and the same, and note the fact that it is the sine-wave fundamental component of the square wave which actually develops the electromagnetic torque in a motor. The harmonics can be considered to come along for the ride on the impressed waveform but do not figure prominently in motor operation (except for the alluded-to tendency to somewhat increase dissipative losses).

Conclusion

This plain-language discussion has endeavored to show that a trapezoidal wave with a limited number of harmonics manifests the salient advantages of both the sine wave and the square wave. At the same time, the proposed trapezoidal wave does not have some of the drawbacks of either sine or square waves. In presenting the case for trapezoidal waves for power lines, it was also pointed out that our present utility power techniques often fail to deliver a really good sine wave at the wall socket. This being the situation, certain arguments for sine waves fall by the wayside in actual practice.

It is well known that professionals and bureaucrats have notoriously missed the boat in past considerations of technical innovations. Also, it is a feather in the ham's cap that amateur radio often has been the source of new and exciting ideas that have resulted in widespread implementations of them. This being true, OM, would you welcome the trapezoid into your ham shack? ■

Transmitter Hunters: Here's Your Ammo For Tracking

For the serious competitor—spend a few evenings with a soldering iron and get the jump on the pack.

A short while ago the age old pastime of transmitter hunting was revived here in Omaha. There have been a number of enthusiastic hunters, but they have discovered that there is a great lack of decent direction-finding equipment.

There were only two of us who could track with any ease. I had a spectrum analyzer hooked up for mobile operation and Bill WA9ASD, a transplant from Chicago, used to be a very active hunter there, but he had become a bit rusty.

Photo A. Inside this rf-proof can lurks a Tempo S-1 HT.

Most everyone else had thrown together pads, antennas, and other hurriedly assembled paraphernalia in anticipation of having a good time. As it turned out, everyone had a lot of fun and the equipment is improving both in type and application.

I quickly found that the spectrum analyzer is great for getting to the rabbit fast, but is not what one would call portable. I had visions of carrying the inverter and a car battery in a backpack, should the rabbit be in the middle of a field somewhere.

I did have a Tempo S-1, but it did not have an S-meter. I had gone over it very carefully before to see if there was some way to put a meter on it. The answer was still no (at least not with just a meter movement). I wondered how difficult it would be to use an external i-f and meter circuit to do the job. After a little testing, I discovered that the output of the second mixer seemed to have a very wide dynamic range. Looking at it (455 kHz) on the spectrum analyzer and increasing the rf at the antenna, the signal was discernible from about .7 microvolts and tracked linearly up to about 5,000 microvolts, nearly an 80-dB range. 5,000 microvolts was roughly the gain compression point at the output of the mixer at 455 kHz. It looked like a good possibility.

I tried several circuits to do the job with varying degrees of success. The one that finally worked was a CA3089E in a circuit stripped down from its intended use. The IC itself has lots of gain, limits at about 12 microvolts, and has a metering pin that follows input level not quite logarithmically from about 1 microvolt up to about 3,000 microvolts (about a 70-dB range). The result is the circuit in Fig. 1. All of the three models built and tested have a range of 0–70 dB when using a 0–1-milliamp meter movement. So it follows that one should need only a single-step 50-dB attenuator to give 120 dB of range. This is, in fact, the case.

When one is operating at the high end of

this range a new set of problems occur—not with the electronics but with the plastic case of the S-1. One just can't be sure whether the signal is coming from the directional antenna or through the case of the radio. This is a common problem on any transmitter hunt.

Since the S-1 is of a modest size, it fits easily into a one-gallon paint can. With the paint buffed off of the lid where it seals, and off of the bottom cover seal, and the can soldered shut (my brand new paint can had a primer coat inside and the bottom was only a paint gasket seal), I could key up with 10 Watts at two inches from the can and the S-1 didn't even know it was there. The rubber duck was elbowed over against the S-1 with two BNC elbows.

That was good enough rf integrity for me. Maintaining this integrity when adding meters, switches, and BNC connectors has to be done with some care and forethought. The first hole I drilled in the can was for a BNC soldered to the lid. I again tested the rf integrity and found that 10 Watts at two inches was *full* quieting. I put a BNC cap over the newly installed connector and was back to full integrity. The 0.5-pF (or so) capacitance between the BNC's center pin and free space was enough antenna to give a full quieting signal with 10 Watts at two inches.

Next, the meter movement: I used a double-wall construction for this (see photos) and a .001 feedthrough. This passed the "10 Watts at two inches" test the first time.

Third was a three-pole, double-throw toggle switch for the 50-dB attenuator mounted next to the BNC on the lid and shielded. The center pole is grounded at all three terminals to prevent capacitive coupling between In and Out. A two-pole switch gave only 41 dB with the 10k removed (see Fig. 2).

Mounting the meter board, the 12-V regulator, the 9-V batteries (explained later), the power switch for the metering circuit, and meter multiplier switch posed no problem. However, adding an LED as a power-on indicator did. The capacitance of the metal in the diode with free space was enough to fail the "10 Watts at two inches" test easily. Two .01-uF capacitors with very short leads soldered between each LED lead and the can cured the leak.

I did add one more hole to the lid. I had a hard time hearing the S-1 with the cover on if there was much ambient noise, even at full volume. An external speaker seemed in order.

I punched a 1½" hole in the lid and soldered a layer of copper window screen (about 1/16" mesh) inside to reseal it for rf and added the speaker. It failed the "10 Watts at two inches" test miserably! A second layer of screen outside with the center insulated by a Teflon™ washer and meshed at 45 degrees to the original restored the rf integrity (see Fig. 5). The only things left to do were cosmetic.

One may wonder why the concern about rf integrity. If one is certain that the only rf getting to the radio is through the BNC connector on the top of the can, one can also be sure that the indications will be solely those coming in the antenna of choice.

Board Construction

Component layout is shown in Fig. 6 and the foil-side positive is shown in Fig. 7. The two .1-uF capacitors and the 22-uF capacitor must be tantalums to ensure that oscillation does not occur.

The two i-f cans are scavenged from an old AM superhet transistor radio. The transformers with the yellow core and the white core are used. There will also be a black- and a red-core transformer that are not used. One of these radios can be procured from a friend or neighbor who has an old one (if you don't). Chances are slim the transformers are bad if the radio is in good mechanical shape.

When construction is finished, tune-up is simple. Tune the S-1 to a weak station that is just barely full quieting and tune both transformers for a maximum meter reading.

An optional meter multiplier circuit is shown in Fig. 3 and is about 40 dB full scale in its most sensitive position. This lets one get a fix on a weak, distant station more easily.

Photo C. Use a double wall for the meter mount.

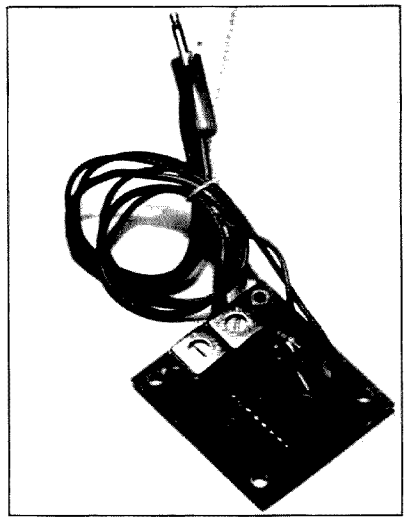

Photo D. A close-up look at the circuit board.

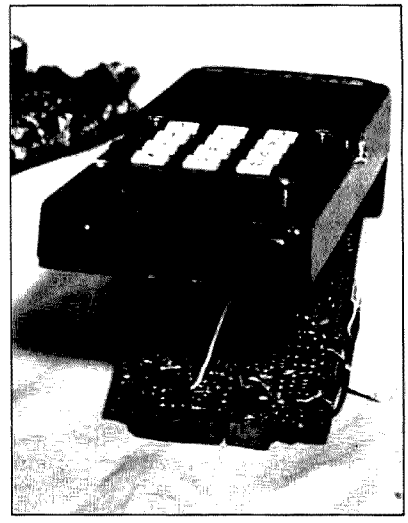

Photo E. Mount the subminiature jack on the bottom right corner of the case.

The 3.3k output resistor was changed to a 2.2k resistor for this circuit.

A few final thoughts—the IC is designed for about 12 V (8–15 V) and current is nearly constant at 22 mA across the range. Performance seems optimum at 10.5–14 V, so I used a 12-volt regulator and a pair of 9-volt batteries in series. Total current demand is about 23 mA, so a couple of the cheapest batteries should work for 2 or 3 hunts. They can get pretty dead before the regulator drops out and the IC gets to its 8-volt minimum and quits.

There is a nearly identical IC, *which in most other applications is a better chip* but has only about 30–35 dB of range on its metered output. It is a CA3189 and *should not be used in this circuit.* I tried one and found it most unsatisfactory.

My Tempo S-2 also has a new jack on its side and the performance is identical except for the antennas one must use.

The power supply is shown in Fig. 4. The 12-V regulator can be any one of the 78X12 series. I used an LM78L12ACH (TO5 package). Note the LED is in series with Vcc and does not draw any extra current.

Connection inside the S-1 and S-2 is as follows: Connect approximately 5 inches of very small coax (RG-174 will do) to a subminiature jack. Mount the jack near the corner of the bevel in the front of the case, as there is sufficient room for a small jack here but no extra space (see Photo C). Next, dress the other end of the coax and connect as shown in detail of the S-1 board (same on S-2). The actual connection is the input pin on the ceramic filter. A capacitor much larger than 47 pF will degrade the performance of the S-1, and less than 22 pF won't couple enough signal out.

Disadvantages: One has to pop the lid every time one needs to adjust the S-1's controls or change frequency and there is, of course, no push-to-talk operation while DF-ing. But, then, one doesn't need that much anyway.

Advantages: Portable, very wide range meter (70 dB—most FM S-meters have only a 20–30-dB range or one has to guess at lights), a cheap addition to an existing radio, and it will work with any radio with a 455 i-f and a discrete mixer.

A footnote: This circuit has been used on the ICOM 4AT, a Regency business-band UHF radio, and a Standard C118. They all needed some isolation to work properly. In all cases the only convenient point to pick off the 455-kHz signal had sufficient baseband noise that the meter gave a substantial reading even with no signal input. The cure was a resistor in series with the 47-pF capacitor in the radio. In the Regency, the optimum value turned out to be 100k; in the ICOM, 47k; in the Standard, 10k.

The ICOM has only about 50 dB of range because it limits in the IC at a lower point than in the S1. The Regency has about the same 70-dB range as the S1, and the Standard also has about a 50-dB range.

To find the proper value of series resistance

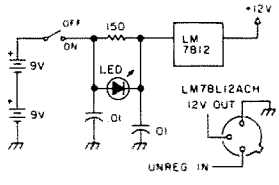

Fig. 4. Power supply.

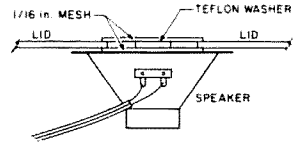

Fig. 5. Two layers of mesh are necessary for rf integrity.

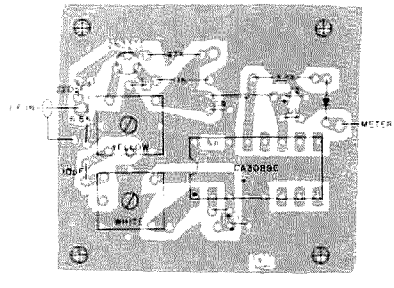

Fig. 6. Component placement.

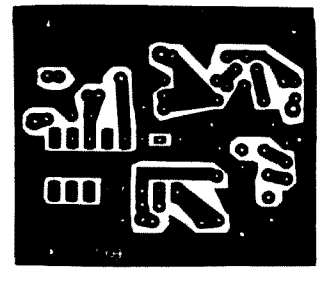

Fig. 7. PC board, foil side.

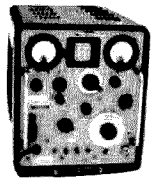
necessary, place a 1-megohm pot in series with the 47-pF capacitor. Adjust the pot until the meter barely reads with no signal input. Then measure with an ohmmeter and put in a fixed value as close to the measured value as possible. 10% tolerance is sufficient (52k was measured on the ICOM).

In the ICOM 4AT, the 47-pF capacitor was soldered to pin 5 of the i-f detector IC. In the Regency and the Standard, the capacitor was soldered to a similar point, i.e., the input of the 455-kHz ceramic filter.

Operation is quite simple. The three connectors, Ant., Spkr., and i-f, are plugged into the radio and the radio is set inside the paint can and secured by a rubber band or some such means to keep it from rattling around. Any suitable directional antenna is connected to the BNC jack on top, the 0–50-dB attenuator is set at 0, the sensitivity switch is set at "Max," and the hunt begins.

I have found during the several hunts I have used this system that after nearly a full-scale reading, the sensitivity switch can be set to "Min" for the rest of the hunt. Likewise, after the second near full-scale reading on "Min," the 50-dB attenuator can be switched in for the remainder of the hunt.



Between the rf shielding and the simplicity of operation, the system's effectiveness approaches that of pseudo-Doppler systems. Especially for stomping through fields. I have found I can get within 7 or 8 feet of a 1-Watt transmitter and the needle barely pegs at full attenuation.

For the experienced tinkerer or kit builder it is a two- or three-evening project. For the inexperienced or perfectionist, perhaps six or eight evenings. ■

Parts List

1	220-pF ceramic capacitor (optional)
1	10-pF ceramic capacitor
1	.04-uF ceramic capacitor
2	.01-uF ceramic capacitors
2	.1-uF tantalum capacitors, 10 V dc or more
1	22-uF tantalum capacitor, 12 V dc
2	1N914s
1	1k resistor, 1/4 Watt
1	2.2k resistor, 1/4 Watt
1	47k resistor, 1/4 Watt
1	6.8k resistor, 1/4 Watt
1	CA3089E (RCA or National)
1	2N2222 Transistor or equivalent
2	455-kHz i-f Transformers (yellow and/or white core from an old transistor radio)
1	Gallon paint can
1	50-mA meter movement
1	.001 feedthrough
2	47-Ohm resistors, 1/4 Watt
1	100-Ohm resistor, 1/4 Watt
1	330-Ohm resistor, 1/4 Watt
1	15k resistor, 1/4 Watt
1	Switch (3PDT)
2	Switches, push on/push off (SPDT)
1	12-V regulator and 2 9-V batteries, or
1	12-V Nickel-cadmium pack or gel cell

SIGNAL GENERATORS

Hewlett-Packard 608F VHF Generator, 10-455 MHz AM-CW-pulse; 0.1 to 300K uv. Built-in xtal calibrator for +/−0.1% accuracy; 16.5×13×21, 80 lbs sh. Used-checked **$425.00**

HP-608C, similar to "F" except 10-480 MHz, 0.1 uv to 1 V output, and no xtal calibrator. Used-reparable with output **$265.00**

HP-606A Generator, 50 KHz to 65 MHz AM-CW in six bands; 0.1 uv to 3 V output. Built-in xtal calibrator for +/−1% accuracy. 10.5×19×13.5, 50 lbs sh. Used-checked **$375.00**

What You See Is Where You're At: Part II

WA8YKN's universal digital frequency display stays on the mark no matter what your rig's mixing scheme.

I was pleased with the response to my article, "What You See Is Where You're At" (*73*, July 1985). There are now quite a few older general-coverage receivers sporting new digital frequency displays, and many of you took the time to write to me.

Most of these letters ended with something like, "I wish it was this easy to add a display to my (Kenwood, Yaesu, Heath, etc.)." After reading this recurring theme for the umpty-umpth time, I decided to design a Mark II version of the simple frequency display that, while retaining the simple programmable i-f offset feature, would be versatile enough to be used with *any* modern transceiver. The resulting display would be totally universal, yet simple enough to be attractive to the average home-brewer. "Universal" is a pretty strong word. It suggests the inclusion of the universe. I fully expect to hear from a reader on the fourth planet of Aldeveron with a Modulated Neutrino-Beam Transceiver. (No doubt the display would indicate quantum field intensity.) Let me say now that I do not have access to every rig ever designed, so there may be one somewhere that this frequency display won't cover. However, I can think of no mixing scheme to which this display cannot be adapted.

If you haven't read the article in the July issue, this is a good time to do so. This display is similar in construction and theory of operation, both of which were explained in detail in that article. That display was based on the 74196 programmable counter. The 74196 was selected for its speed, which is of top concern when tracking the low-powered vfo of a shortwave receiver over a 30-MHz range. Also, it is programmable, allowing a preset equal to the i-f frequency.

The 74196, however, will count only in the *up* direction, and as stated in the article, can be used only on receivers in which the vfo tunes in the same direction as the desired frequency. Virtually all single-conversion shortwave receivers, and even some amateur transceivers (such as the Argonaut) use this

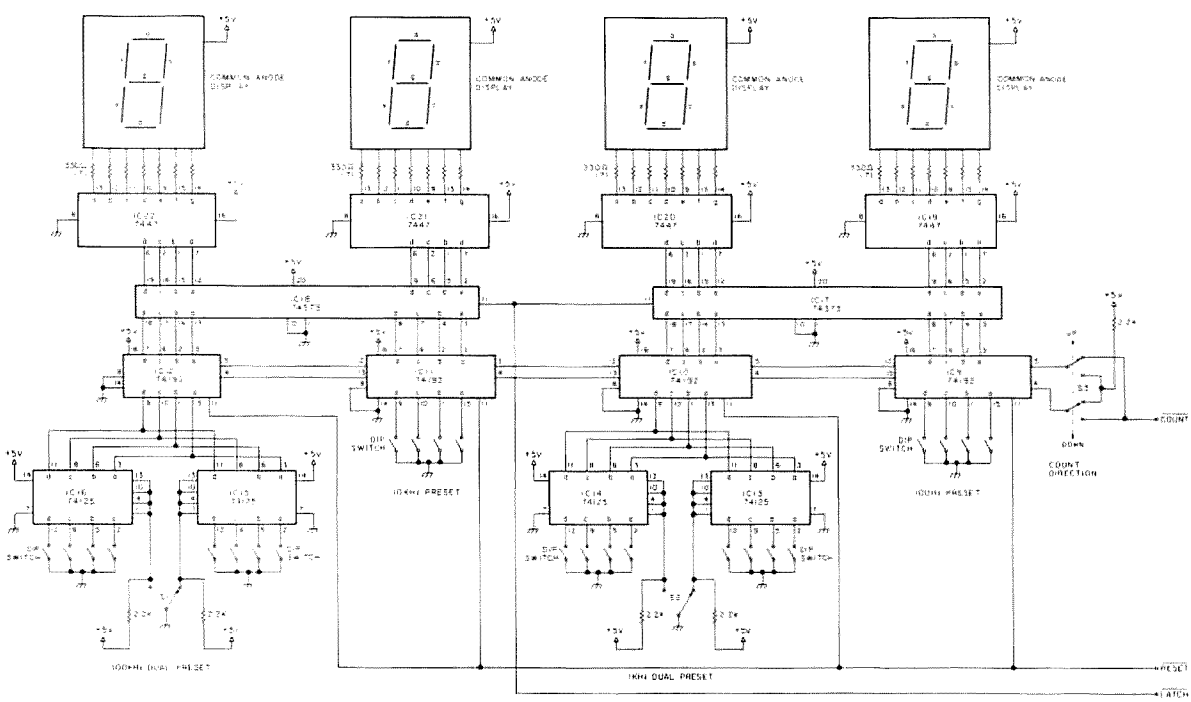

Fig. 1. Schematic of the "Frequency Display II."

scheme, and for these rigs the display works perfectly.

Many other transceivers use a multiple-conversion design in which the incoming signal is premixed using a crystal-controlled oscillator and mixer. The vfo always tunes over the same frequency range regardless of the band being used. And to complicate matters, the vfo usually tunes backwards. In fact, on some rigs the vfo will tune backwards on some bands and forward on others.

The vfo always starts with the same frequency, also, but our amateur bands do not. Some of them begin on X.000 MHz and some begin on X.500 MHz. Two offsets will therefore be required, just as most analog dials have two sets of markings. While we're at it, we should have a way to shift this offset by 3 kHz to allow for USB and LSB operation.

The design presented here overcomes all these problems. The 74192 counter is used, allowing both up and down counting. While not quite as fast as the 74196, it is adequate for our needs. The multiple preset for the 100-kHz and 1-kHz digits was accomplished through the use of 74125 tristate buffers, which select one of two sets of DIP switches for those digits.

For simplicity, only the digits to the right of the decimal point are displayed. There is no need to display the MHz digits, as we should be able to remember what *band* we're on!

At this point a problem surfaced. I don't own any equipment that uses this mixing scheme! I discussed this with John Farmer WA8GYP, who had been the first to evaluate the previous display. With only moderate arm twisting, John offered his Yaesu FT-101EE as a guinea pig.

This settled, I built the display in a few days, and the following weekend journeyed to far-off, exotic New London, Ohio, to try it out. The FT-101 series has the vfo frequency and 13.5 V dc available on the accessory jack, so no modification to the rig was required. Everything worked as planned, and John now has the only digital FT-101EE in New London. (The natives are suitably impressed.)

Circuit Details

Fig. 1 shows the count and display logic. The count input to the first 74192 is via S3, which selects either up- or down-counting modes. The Carry and Borrow outputs are connected to the up and down inputs of the next stage, and so on.

Resetting the counters by pulling pin 11 low loads the number present at the preset inputs, pins 15, 1, 10, and 9 (binary a, b, c, and d respectively). On the digits requiring only one preset, the number is set directly with DIP switches. Those digits requiring two presets use two sets of DIP switches, each isolated via a 74125 tristate buffer. Switching the enable lines low selects that preset. The other set of DIP switches (its buffer in the high-Z state) is ignored.

The latch and decoder logic operates exactly as in the earlier display. The 74373s happened to be on hand, and each one functions in this circuit just like *two* 7475 latches. This saves space and lowers the overall parts count.

Photo A. Why is this man smiling? See text!

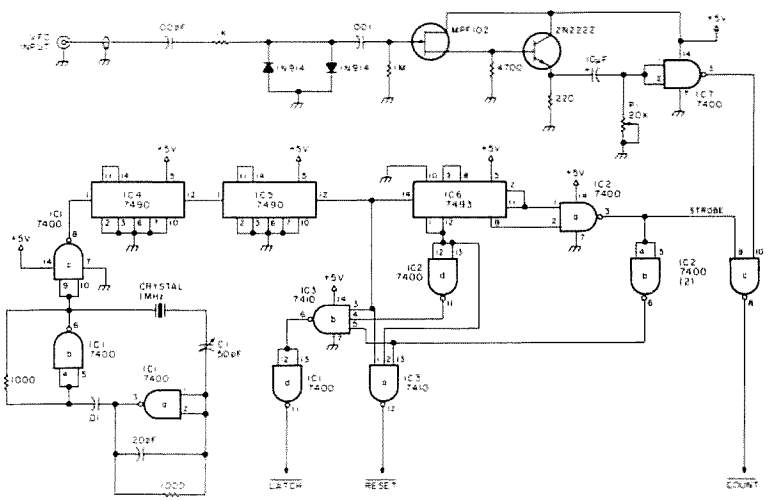

Fig. 2. Input and control logic.

Fig. 2 shows the timebase and control logic as well as the vfo-input circuit. The Count, Latch, and Reset signals connect to the appropriate inputs of Fig. 1. If you look closely at Photo B, you will notice a 5-MHz crystal and an extra 7490. At the time, I didn't have a 1-MHz crystal, so I used the 5-MHz one with a divide-by-five stage to produce the signal.

This worked for testing the operation of the display, but the old FT-243 crystal drifted quite a bit, so ultimately it was replaced with a quality 1-MHz crystal (soldered in place) and the extra divide-by-five circuit was disconnected.

Most modern transceivers have 12 volts available to power accessories, so the circuit of Fig. 3 uses an LM317 to reduce this voltage to the regulated 5 volts required by the display ICs. The 1000-Ohm pot (P2) is adjusted for 5.00 volts *before* the output is connected to the rest of the display. TTL ICs do not like overvoltage.

I recommend the use of LS (low-power Schottky) ICs over the standard TTL versions. Although functionally identical, the LS versions are slightly faster and draw only a fourth the current consumed by standard TTL ICs. This adds up to less drain on the power supply and considerably less heat buildup inside the cabinet, which is a big plus for stability.

When I built this display, the only 74192s I

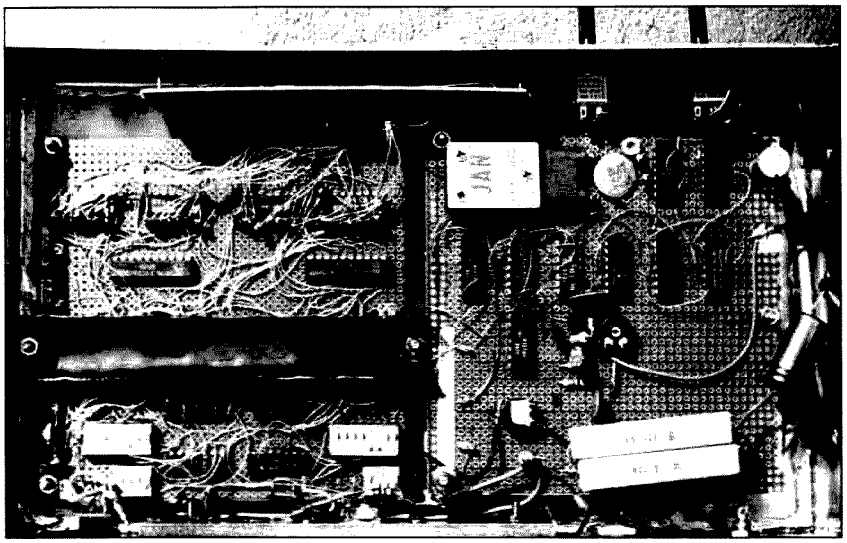

Photo B. Inside the frequency display. Plenty of room for everything. The heat sink for the regulator is mounted on the rear panel.

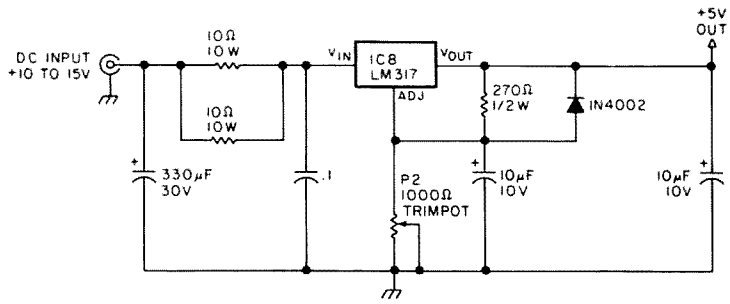

Fig. 3.

had on hand were some old high-power versions, and though they worked fine, they ran very warm. In fact, I ended up bending a strip of thin sheet aluminum to form a U-shaped heat sink, which I bolted down across the entire row of counters. A dab of white silicone grease on each IC carried the heat away, but the use of 74LS192 counters would eliminate the need for such measures.

No pinout is given or the common-anode displays since that varies with size and manufacture. If you purchase the seven-segment displays new, they will have pinout information with them. If you use surplus "bargain-pack" assortments (like I do), it is a simple matter to determine which pin goes where.

The anode usually is connected to several pins, easily found with an ohmmeter. A few minutes with a dc source, a current-limiting resistor, and two clip leads will identify the rest. A $1.98 bargain pack produced three large (.7") displays in which all segments worked, and a smaller (.3") one which I used as the 100-Hz digit.

Construction

I built the frequency display on two five-inch square pieces of perforated Bakelite™, one piece for the timebase and the other for the count and display logic. Connections were made point to point, using Radio Shack wire-wrap wire. Layout is not particularly critical (see Photo B for details).

The enclosure was made up from copper-clad circuit-board material soldered at the seams. I bolted a ¼" thick strip of aluminum to the rear of the enclosure to act as a heat sink for the LM317 voltage regulator, and the opening for the display was cut with a Radio Shack nibbler.

The displays were mounted on a small scrap of perfboard mounted directly behind the opening. I used red-tinted plastic as a light filter. The blank leader from developed 35-mm color negatives also works well here.

The location of the three switches will depend on the mixing scheme of your transceiver. In the case of the FT-101, the vfo always runs in the backwards direction, so the up-down switch, S3, was mounted on the rear. (It could be eliminated if you have only one application in mind.)

S1 and S2, which select the display offsets, were mounted on the front panel to the left of the readout. A piece of ⅛-inch-sheet aluminum and two scrap angle braces bolted together form the lid. Be sure to drill plenty of ventilation holes over the regulator and the 10-Ohm resistors to let the heat escape.

After painting, the switches can be identified with Radio Shack rub-on lettering. The completed display measures 11" wide by 2" high and 6" deep and is quite attractive with the FT-101 (see Photo C).

Setup and Operation

The timebase oscillator must be adjusted carefully to 1 MHz if the display is to be accurate. Either a good frequency counter or a receiver set to WWV can be used, adjusting C1, the 50-pF trimmer capacitor, for zero beat. An oscilloscope triggered on the Strobe signal (IC 2, pin 3) should display the timing waveforms shown in Fig. 4.

With the display operating but not connected to the transceiver, the DIP switches can be checked out for proper operation. With all the switches closed, all digits will read zero. Opening one of the four switches for a particular digit will cause the value of that switch to be displayed. For example, opening switch a on the 100-Hz digit will cause that digit to display 1; switches b, c, and d will similarly display 2, 4, and 8.

Opening more than one switch adds the values. To display 3, for example, open switches a and b. Opening all four switches will cause that digit to go blank. This isn't a fault with the display, it's just that all four switches add up to fifteen, and that's why the 7447 decodes binary 1111.

The digits with two presets are checked out in the same way, but each set of switches can be displayed only when selected by S1 or S2.

If everything checks out, it's time to hook the vfo signal to the input. Most transceivers have a vfo input available at the rear panel, so take a look at your manual. If it's necessary to provide your own tap, find the output of the vfo buffer and you'll see a capacitor coupling the vfo signal to the mixer. That's the point you want. Tap in with a 100-pF capacitor and bring the signal to the rear panel using small coax.

The input-gate bias is set by slowly adjusting the 20k trimpot, P1. Somewhere around the middle of its range, the display will start counting the vfo. In fact, with all the DIP switches closed and S3 in the up-count position, we now have a four-digit frequency counter reading out the last four digits of the vfo frequency.

On John's FT-101, the vfo tunes from 9.200 MHz at the low end of each band to 8.700 MHz at the high end. The display reads .2000 to .7000, counting backwards. By switching S3 to the down-count position, the display will read .8000 to .3000, and will now be counting in the proper direction.

Setting the DIP-switch presets is simple. Start with 80 meters. Set S1 to the X.500 position and set the transceiver to 3.500 MHz. With the FT-101, the display will read .8000. Adding 7 to the 100-kHz digit will cause it to read (1).5000—just what we want—so open DIP switches a, b, and c. The display will now agree with the dial.

Next, try 40 meters, setting S1 to the X.000 position. This selects the other set of DIP switches for the 100-kHz digit. Tune the dial to 7.000 MHz and, on the FT-101, the display will again read .8000. This time we need

to add 2 to the left-most digit to cause it to read (1).0000, so DIP switch b is opened.

The USB-LSB switch, S2, is handled in the same manner. Set the transceiver on upper sideband and zero-beat a signal. Set switch S2 in the USB position and note the frequency displayed. Now switch the transceiver to lower sideband and again zero-beat the same signal. Set S2 in the LSB position and note that the display is reading low by 3 kHz. Adding .0030 to the count will fix it, so open switches a and b on the DIP switches currently active for the 1-kHz digit.

With the display now properly set up, using it is simple. 160 meters, 80 meters, and two segments of 10 meters require S1 to be set in the X.500 position; 40, 20, 15 and the rest of 10 meters require S1 to be in the X.000 position. Also, switch S2 must be set to agree with the mode of operation.

Adapting to Other Transceivers

Although the FT-101 was used in the previous example, any transceiver with a backwards-tuning vfo will require exactly the same procedure to determine the presets required and program the display. Any transceiver in which the vfo tunes forward on some bands and backward on others still will require two presets on the 100-kHz digit, since the displayed count will change when switching from up- to down-counting modes, but it should be possible to use a DPDT combining S1 and S3 into a single control. In this manner, the operation of the display with such a transceiver would be identical to that with the FT-101.

If your vfo always tunes in the forward direction, you probably would be happier building the 74196 version I presented in the July issue. This one will do it, but the extra complexity is unnecessary.

Accuracy

There is only one oscillator in a single conversion superhet, the vfo. It is always removed from the received frequency by exactly the i-f frequency—no more and no less. But in a modern transceiver using a premix oscillator and a bfo in addition to the vfo, there exists the potential for error.

Commercial frequency displays get around this by counting *all* the oscillators and displaying the sum. This type of circuit, however, is pretty complex for a home-brew project. By counting the one that tunes and presetting the counters to make up for the rest, a much simpler display results, one that is not only practical and low-cost but easy to understand and build.

How much of a trade-off is this? Let's consider. We've got the bfo covered with two presets available for USB and LSB, so even if these oscillators are slightly off, we can compensate with the DIP switches. We're *counting* the vfo, so there's *no* chance of error there. So the only possible source of inaccuracy is the premix oscillator.

If we set our DIP switches for one band, there's a chance that the crystal for another band may be a little high or low, causing the display to be in error. However, if we assume

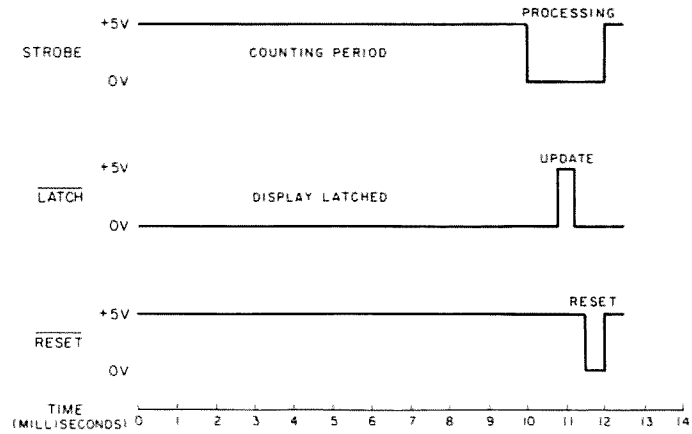

Fig. 4. Control timing.

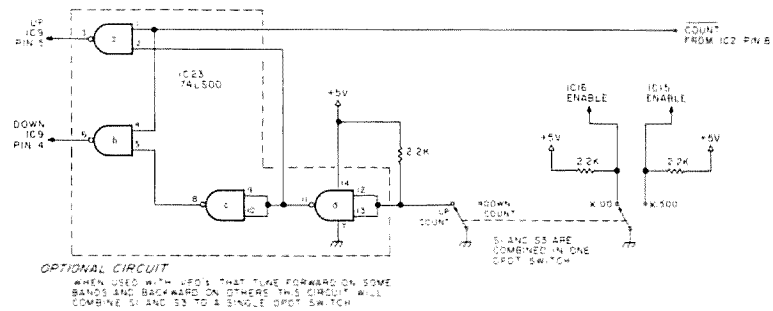

Fig. 5. Optional circuit.

that the manufacturer of the transceiver used reasonable care in designing and building his product, the error should be small. On John's FT-101EE, all bands were accurate to within 100 Hz except the 160-meter band and the 29.500 segment of 10 meters. Both of these were 200 Hz off.

Although this does represent a small error, this does *not* mean that the tuning is in any way ambiguous. The error does not change, and if John must know his *exact* frequency, he has only to subtract 200 Hz on these two bands. The resolution is there, and it is still possible to return within 100 Hz to any frequency.

Also to be considered is cost. A commercial display using the oscillator-summing method will set you back $200–$250. By settling for a small potential for error, we save a couple hundred bucks! Did WA8GYP

Photo C. Shown here with the Yaesu FT-101EE, this version of the simple frequency display can be used on any analog transceiver.

consider it a fair trade? Look at Photo A, and note the big smile on John's face! This display will cost around $40 purchasing all parts new. If you have a typical home-brewer's junk box, it can be done for much less.

Final Thoughts

The potential is here to add a simple, low-cost frequency display to just about anything. A little time with the manual of a particular piece of gear should give you a clear idea what will be required, and you can modify my basic layout to suit your individual needs. The display can also be tailored to your operating habits.

For example, I usually operate RTTY and CW. My only phone activity is an occasional contact on 75 meters. Since I never use USB, that preset could be used to make up for the 2125-Hz error on RTTY caused by feeding audio tones into the transmitter (AFSK). The display would then show my actual mark frequency! Get the idea? There's a lot of room for originality here.

Home-brew projects are fun and educational. It's an amateur tradition. And when your buddy sees those beautiful red-glowing digits you can say, "Yeah, I built that last week." That, my friends, is a feeling I cannot put into words.

I would enjoy hearing from anyone interested in this project, and will try to help with any specific questions. Please include an SASE, however. ■

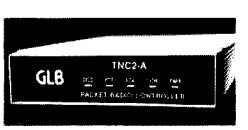
PACKET RADIO GOES PORTABLE

GLB ELECTRONICS
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement: 9 to 15 Volts DC @ 25 mA typical
Dimensions: 4.6 X 5.90 X 1.0 inches
Total Weight: 12 ozs.



PKIL—Wired and Tested
List— $239.95
Amateur net— $209.95

GLB MODEL TNC-2A KIT

Just when you thought TAPR TNC-2 Kits were a thing of the past, GLB — the first commercial producer of Packet Controllers — Joins the "TAPR Revolution" at last!

GLB is now the exclusive supplier of TNC-2 Kits.

Total Solar

Plug your shack into the sun! Here are complete plans for energy independence.

Photovoltaic electricity is rapidly becoming the technology of choice for powering amateur radio stations. With the price of photovoltaic panels falling, large arrays are now within the range most hams can afford.

To make the most efficient use of the available energy, a photovoltaic controller will be needed. If the solar array were to be left connected to the batteries all the time, severe overcharging would occur, resulting in excessive electrolyte gassing and unnecessary loss of electrolyte. Physical damage also can result in the form of warped plates and the dislocation of the plate's lead paste. Likewise, in times of low periods of sunlight, the batteries could become damaged by deep-discharging.

The controller described below will allow the direct charging of lead-acid batteries without the need of a blocking diode (in the direct-charge mode). It also will provide a low-state-of-charge warning system. When the batteries become fully charged, a second, floating charge system will keep them topped up and ready to go. Energy-load management can also be installed.

Charging Techniques

The techniques by which batteries are charged via photovoltaics have been and still are varied. However, two basic technologies are used: shunt mode and direct (switching) mode.

In the shunt mode, array power is diverted from the batteries by shunting power to ground on the array side of a blocking diode. The battery-terminal voltage is monitored, and by a feedback loop to the controller, excess power is diverted. This excess energy is dissipated as heat, usually by resistors.

With the direct mode, a relay or transistor switch is in series between the array and the batteries. As charging progresses, the battery-terminal voltage will rise. It is then possible to approximate battery state-of-charge to this terminal voltage. By monitoring the battery-terminal voltage, the controller can decide when to stop current flow and may do so by opening the relay or turning off the switching transistor.

While the shunt-mode controller can operate with no moving parts, the heat built up by the resistors has to be removed. This calls for a large bulky unit. Likewise, if the switching controller uses a relay, we now have one moving part that may go bad in time. The use of a transistor switch will get by that problem. However, the transistor must now be able to pass the total current of the array. Careful heat-sinking will be required. There is also the voltage drop across the transistor junction that will reduce efficiency.

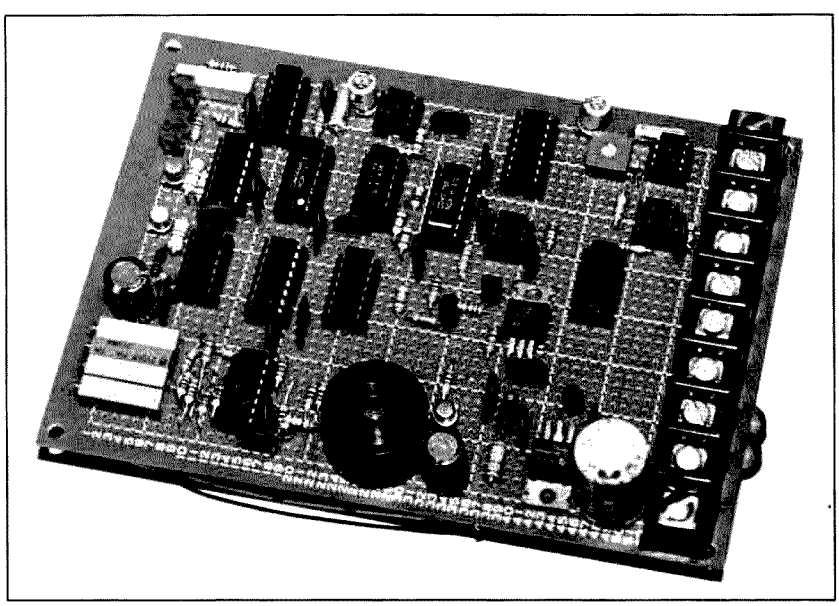

Photo A. The complete control logic. Some minor changes were made to the circuit after the photograph was taken.

A Better Controller

Look at Fig. 1. The basic circuit for the controller makes use of the LM339 voltage comparator. This chip provides an output that is at a high state when the inverting input is below the reference voltage. When the voltage on the inverting input is equal to or greater than the reference voltage, the output switches to a logic low.

The reference voltage comes from the power-supply circuit. A 78L05 provides a constant 5 volts for the comparators while a 7805 regulator was wired to provide 10 volts for the remaining logic. The usual bypassing was done so the circuit logic can be used around rf fields.

To set up a "voltage window," comparators A and B connect first to a 4050 noninverting hex buffer. From there, the output of the buffers connect to a NAND gate of a

4011. The other two gates make up an R/S latch. When the battery voltage drops below the "reset" window, a logic 0 is applied to set the latch. The output of the R/S latch will go to logic 1 and into the 4082.

The output will stay this way until the battery voltage rises above the float-charge level. At that time comparator A will go low, resetting the latch and turning off the output. An inverting buffer, a 4049, will then turn on transistor Q1 and light the float-charge LED.

Comparator C is wired as the first two, but instead of monitoring the battery voltage, its job is to look at the array voltage. If the array voltage is above 10.5 volts, the output will remain a logic 0. A second gate of the inverting buffer provides the proper logic sense for the 4082.

The comparator will not be able to do its job, however, because the relay will be closed. This will fool the comparator into believing the battery voltage is the same as the array voltage. To get around this, some means of opening the relay contacts is needed so the comparator can "see" the array voltage. The relay must then close to continue charging. This is where the 4082 and the clock circuit come into play.

The clock that I had planned originally used a color-burst crystal and an MM5369 17-stage divider. However, to slow the clock

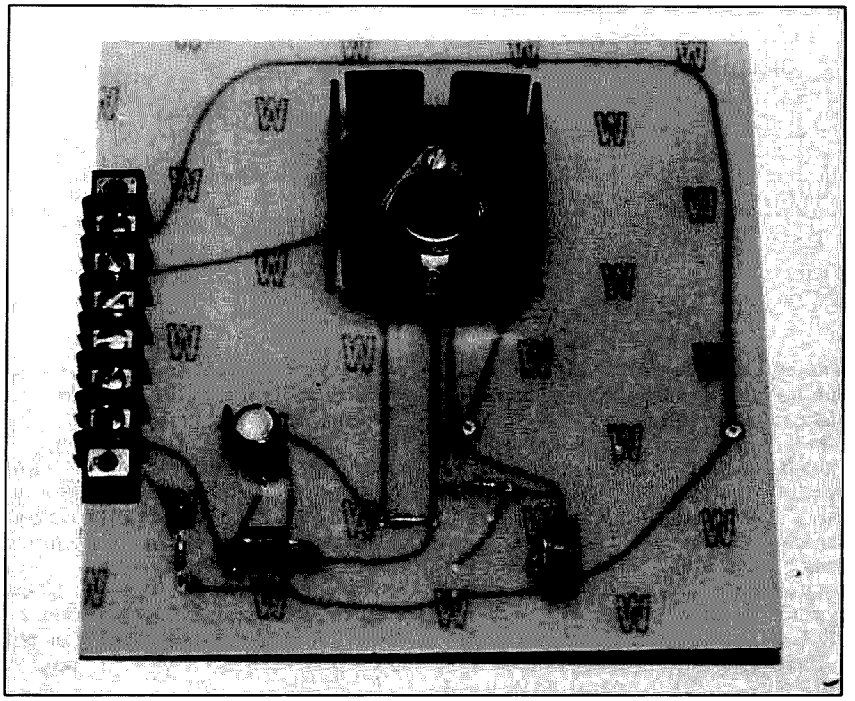

Photo B. The float regulator board. Since the circuit is simple, a PC board was made using rub-on resist. Note heat sink on the LM317K.

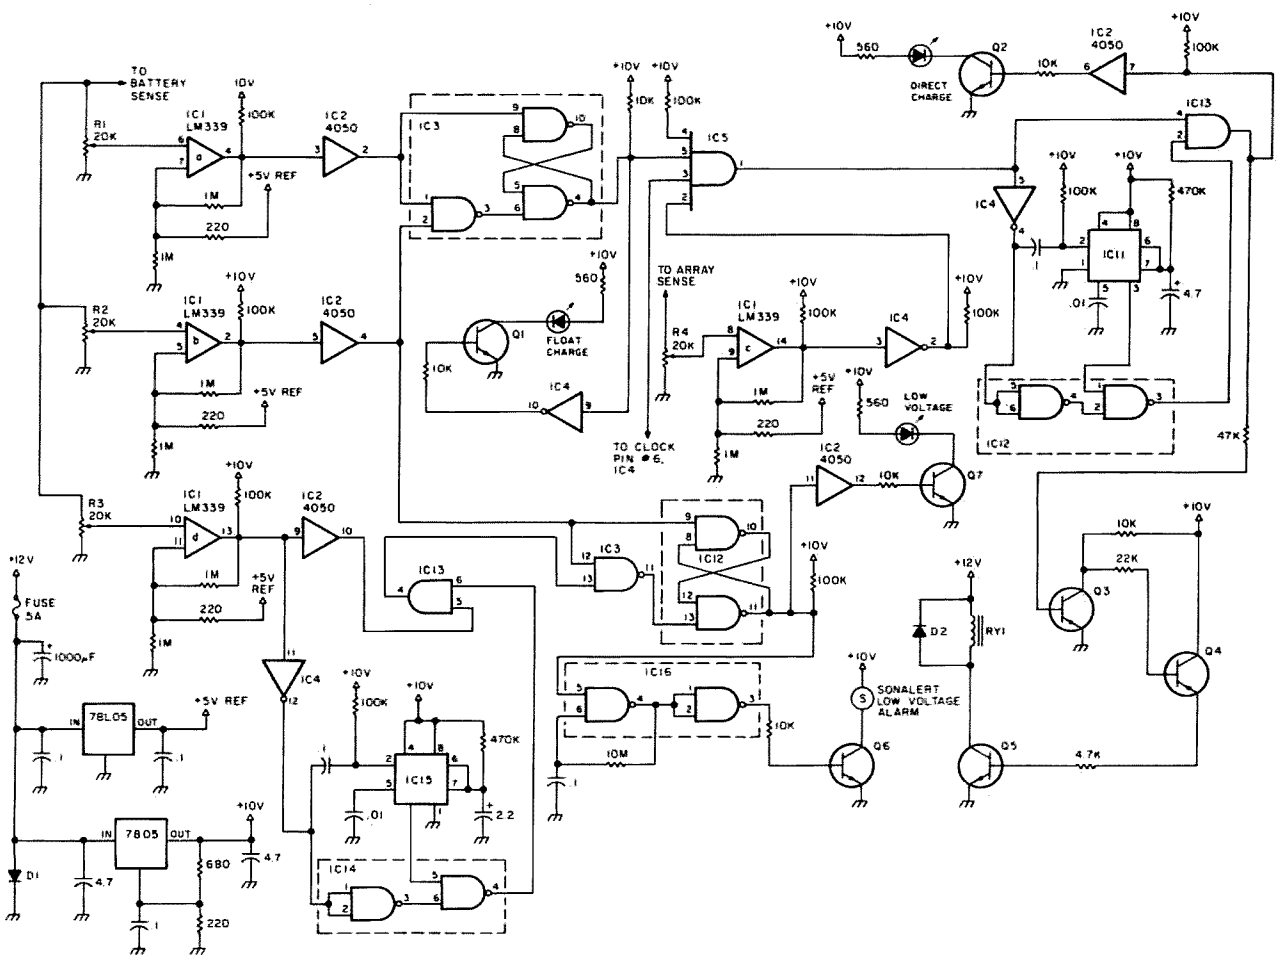

Fig. 1. Schematic diagram.

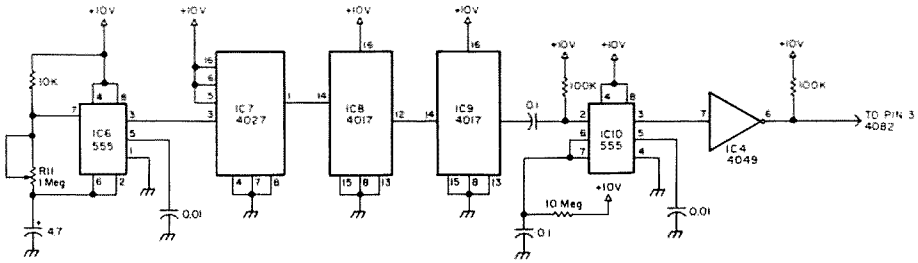

Fig. 2. Clock circuit.

down to the time I needed required the use of either a large divide-by chain or expensive and hard-to-find components.

In the early stages of design, I used the clock shown in Fig. 2. It worked so well that I decided to stay with it. The 555 timer is wired as an astable oscillator. Resistor R11 and capacitor C10 control the frequency. By adding a clocked flip-flop to the timer's output that acts as a binary divider, a perfectly symmetrical square wave is available for the divide-by chain. A 4027 does the job nicely.

The square wave is then connected to a 4017 divide-by-10. A second divide-by-10 slows the clock pulses down to a usable period. The output of the last 4017 is connected to a second 555 timer, wired as a one-shot.

Again, resistor R12 and capacitor C11 set the time. The output is inverted by the 4049 and held to a logic 1 by the 100k resistor. The output then goes to pin 3 of the 4082. Depending on the setting of the trimmer control of R11, there will be a high-to-low pulse, returning to logic 1, on pin 6 of IC4 every 2 minutes to every 90 minutes.

With the "window comparators" and the array comparator all at a logic 1, the clock also will be at a logic 1. The remaining pin of the 4082, pin 4, is held at logic 1 by the 100k pull-up resistor. That pin will be reserved for future use.

Since the 4082 is an AND gate, all inputs must be at logic 1 for the output to be logic 1. If either the R/S latch goes off, the array voltage drops, or the clock pulses, then the output of the 4082 will go to logic 0. This is how the array comparator can "look" at the array. When the clock goes low, the output goes low, turning off the relay.

If the array voltage is above 10.5 V, then the output of the array comparator stays low (logic 0). (Of course, that is being inverted by the 4049 so the 4082 will see a logic 1.) If the voltage is lower than 10.5 V, the output of the comparator will switch logic and the 4082 will keep the relay off. The same thing will happen when the battery becomes fully charged. The float voltage of 14.5 volts will turn off the latch and the 4082 will lose one of its inputs. It, in turn, will shut off the relay. This will prevent overcharging of the battery.

The clock pulse at the end of the divide chain is just that, a pulse. The relay must open and the contacts must stop bouncing. At that time, the array comparator can decide the status of the photovoltaic panels. To do just that, a pulse-delaying circuit was needed.

". . . the thrill I get from communicating around the world with solar energy is beyond words."

When the output of the 4082 goes to a logic 1, pin 1 of the 4081 is held to a logic 1. Pin 2 of the 4081 goes to the pulse-delay circuit. When pin 1 of the 4082 goes to logic 1, it is inverted by a 4049. This starts timer IC11. The output of this timer stops the flow of logic until it times out—in this case, about 3 seconds.

When that time is up, the logic 1 is now allowed to go to pin 2 of the 4081. With both pins now at logic 1, the output of that chip also goes to logic 1. The output goes two places. First, it turns on Q2, the "direct charge" LED, via a 4050 buffer. Next, it turns on the transistor switching needed to operate the relay. The TIP 29 transistor will handle about 1 Ampere of coil current.

If the battery voltage rises to the float setting of 14.5 volts, the relay will open. When it does, the float-regulator circuit will take over and maintain the battery in a float condition. The float current will depend upon the condition of the batteries and the amount of photovoltaic energy. The float-regulator circuit is connected across the relay contacts of the main relay. When the clock times out and the relay opens for the array check, there is little or no contact burning.

Fig. 3 shows the float-regulator circuit. As can be seen, an LM317 is used in a conventional power-supply configuration. I had to place a diode in series with the output of the regulator chip because the regulator sometimes would not start up—perhaps because of the battery voltage on the output of the regulator.

With this diode in place, there is no trouble with the regulator operating as it should. Trimmer pot R1 sets the voltage of the regulator. It can be used to adjust the current flow of the regulator when in the float-charge mode. Its adjustment is not critical. The LM317 requires a heavy sink to pass the maximum 2 Amps of current.

To keep from discharging the battery bank too deeply, a low-voltage warning system was installed. It operates almost exactly like the circuit used to monitor the full-charge float system. The last comparator of the LM339 is used to monitor the low-voltage point of 11.7 volts.

To keep the warning system from turning on and off with a load, the pulse-delaying circuit is used. If it was not connected, then the warning tone would follow the CW as the transmitter would load down the batteries. A rather exotic sidetone generator! This also allows a high-current turn-on load to be ignored (such as a power inverter or motor).

Also, when the batteries become low, I wanted the warning to sound until they were almost recharged. If not, a dead battery bank would shut off the warning when the next day came and the panels starting charging the bank.

When the battery voltage dips to 11.7 volts, pin 12 of IC4 goes low. This trips the time-delay of 2 seconds. At that same time, the comparator's output is applied to one side of

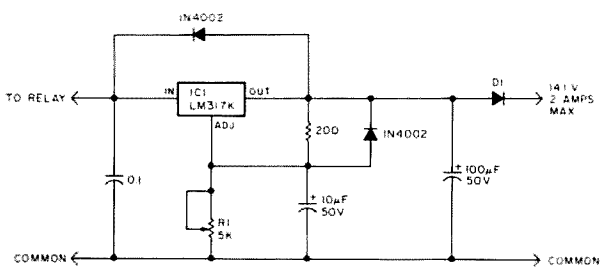

Fig. 3. Float-regulator circuit.

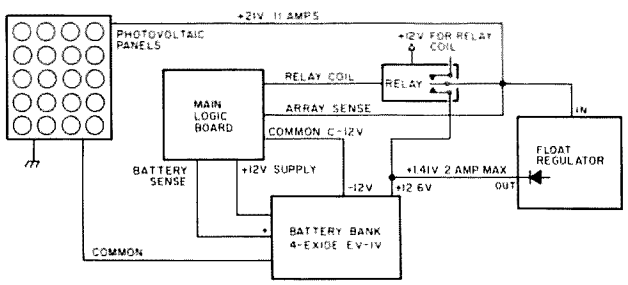

Fig. 4. System diagram.

an AND gate, IC13. When the 555 timer times out, the other half of the AND gate gets a high logic. With the reset comparator (B) high, the R/S latch is set. This turns on the gated oscillator which drives a piezo-electric sounder. The latch also drives Q7 on via the buffer gate and turns on the low-voltage LED.

When the voltage reaches the reset point of 12.5 volts, the R/S latch is turned off. It should be noted that the reset voltage and the reset window voltage will be the same. I didn't want to use another comparator.

With the proper transistor switching, a relay could be placed in use as a low-voltage disconnect. A remote solar-powered repeater could be wired to disconnect the power amplifier when the battery bank is low. Then reconnect the amplifier when the batteries become 60% charged.

Operation

In normal use, the controller logic will work as follows. Assume full array power and a 90% charged battery bank. At sunrise, the array voltage will rise above 10.5 volts. Since the battery voltage is below the reset point of 12.5 volts, the relay is turned on and full array current is allowed to flow into the batteries.

Every hour the clock will time out and cause the relay to open up. The array comparator will look to make sure the array is still 10.5 volts. It is—and the relay will again close. As the batteries increase their charge, the terminal voltage will rise. When it comes up to the float-set voltage of 14.5 volts, the relay will drop out. The float regulator will now supply a maximum of 2 Amps to the battery bank. This current will fall back to about 500 mA to 1 Ampere.

If a load is applied to the batteries, the float regulator will try to supply the maximum current of 2 Amperes. If the load is great enough, the battery-terminal voltage will fall to the reset point of 12.5 volts and again the relay will be turned on and full array current will be applied.

Every hour the array voltage will be checked. When sunset arrives, the array voltage will begin to drop. When it goes below 10.5 volts, the array comparator will tell the logic to shut off the main relay. The system will then wait until the next morning, when the whole process repeats itself.

As can be seen, the relay will remain closed as long as the batteries need charging. This can be used as a cheap and dirty load-management system. By connecting the load through a second set of contacts on the relay, only when the batteries are fully charged will the load be connected. Of course, only nonessential loads should be done this way.

Putting It Together

Construction is best done on perfboard. As there are several options, no printed circuit was designed. One may not wish to install the low-voltage system. That choice is up to the builder.

Since the controller uses CMOS devices, some care should be used in their handling.

Parts List—Main Logic

R1, R2, R3, R4	20k Ten-turn trimmers
IC1	LM339 Quad comparator
IC2	4050 Hex buffer
IC3, IC12, IC14	4011 Quad NAND gate
IC4	4049 Inverting buffer
IC5	4082 4-Input AND gate
IC6, IC10, IC15, IC11	555 Timers
IC7	4027 Flip-flop
IC8, IC9	4017 Decade counters
IC13	4081 Quad AND gate
IC16	4093 Schmitt trigger
Q1, Q2, Q3, Q6, Q7	2N2222A
Q4	2N2907
Q5	TIP 29
78L05	
7805	
C1	1000 uF @ 25 volts
D1	1N4003
D2	1N4002
RLY	12-Volt coil, 10-Amp contacts, DPDT
R11	PC mount, 1-meg trimmer
SY1	Piezo-electronic sounder
Regulator Board	
IC1	LM317K Regulator
R1	5k PC-Mount pot
D1	3-Amp Diode (use RS/276-1144 for 3 Amp)
	Heat sink for regulator

Try to avoid static since this will damage the chips. Also, there are some unused gates. The input pins should not be left floating. They must go somewhere! Either tie the pins to Vcc or to ground. (Not shown on the schematics, .1-uF capacitors are placed at all Vcc pins of the chips.)

There is nothing about the controller logic that is carved in stone. Feel free to change or to delete parts of the logic not needed.

The circuit could be wired for different types of ICs. The 4011 chips that I used for an R/S latch can be replaced with a 4044 quad latch. Likewise, the 555 timers can be replaced with a 4528B. Of course, that is one reason no PC was done. In fact, all the 555 timers needed could be replaced with one quad 555 timer, the 558. The rest of the parts are very common.

There are only two components that should not be substituted: the main relay and the 10-turn trimmer that set up the comparator. The relay I use here is surplus and was picked up at a local flea market. The contact rating is 25 Amperes. The relay must be able to handle the total current of the array.

The best way to build the controller is in modules. Photo A shows the finished logic board. This way, parts of the circuit can be tested before moving on to the next stage. The modules can be placed in groups on the single perfboard. The main modules are: comparators, power supply, reference supply, pulse-delaying circuit, and output circuit. The low-voltage warning system would be installed last.

Calibration

To set up the controller, you will need a digital voltmeter, a VOM or logic probe, and a variable power supply.

While the low-voltage warning system will be adjusted last, it may or may not sound. To keep it from going off until needed, pull the 4093 from its socket. Replace it when setting the warning system.

Apply 12 volts to the circuit. Check that +5 volts at the output of the 78L05 is there. Also check for +10 volts at the output of the 7805. Temporarily connect the battery-sense voltage to the power supply. Reading the voltage from the digital meter, set the supply at 12.5 volts. Monitor pin 2 of the LM339 and adjust trimmer R2 until the logic switches from high to low. Rock the supply about and make sure that pin 2 goes low at 12.5 volts.

To set the float point, adjust the supply to read 14.5 volts. Monitor pin 1 of the LM339. Adjust trimmer R1 until the logic goes low (logic 0). Assuming that the rest of the circuit was wired correctly, the float-charge LED should light when the voltage is over 14.5 volts.

The next comparator will be the array comparator. Connect a wire temporarily to the "panel sense" and adjust the supply to read 10.5 volts. Monitor pin 2 of the 4049. Adjust trimmer R4 until the logic goes low. Increase the voltage and pin 2 should go to a logic 1.

The last comparator will be the low-voltage warning. Set the supply for 11.7 volts and adjust trimmer R3 until pin 12 of IC4 goes low. Increasing the voltage should make the logic switch low. At this point, the alarm should sound.

All the voltage set points should be adjusted

more than one time. You want the logic to switch at the required setting.

Remove all the jumpers and disconnect the power supply. The controller can now be placed in use. I used industrial conduit boxes to house the circuit boards. Since I use both solar and wind power to operate the station, both control systems are located together.

Troubleshooting

If something is not working, then help may be had at the test points. Make sure that the 555 oscillator is running in the clock. Look at pin 3. By following the pulse through the divide-by chain, any problems will be uncovered. Pin 1 of the 4082 must be logic 1 (high) for the relay to close. If it is and the relay is not closed, check for trouble in the pulse-delaying circuit or the output switching. If the wiring is fine, then start looking for bad chips. Use sockets.

Before the controller is put into use, some information about batteries may be helpful. There are two basic types of lead-acid batteries on the market, the lead-antimony and the lead-calcium. As the name implies, the lead-antimony battery contains lead alloyed with antimony while the calcium battery is composed of lead alloyed with calcium. Both batteries have voltage outputs of about 2 volts per cell.

The lead-antimony battery must now and then have its cells equalized. This is done by slightly overcharging the battery until all cells read the same specific gravity. The cells use up a greater amount of water than the calcium battery. In fact, most of the so-called "sealed automobile batteries" are lead-calcium. The lead-calcium battery is less likely to sulfate. However, the lead-antimony battery has a much better life cycle and, because you can check the cells for specific gravity, much data may be obtained on battery condition.

Caveat

There is a fact that should be noted. The amount of recharge current should be adjusted to the amount of storage. In other words, don't try to recharge 500-Ah batteries with only 1.5 Amps of solar energy. While it will in fact get the job done, the controller will not be needed. With array current under 35 Watts, no controller would be needed—just a diode to prevent discharging at night.

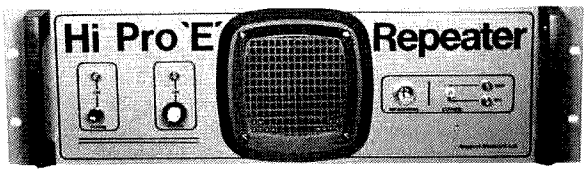
On the other hand, don't try to charge up a motorcycle battery with 14 Amps of current. The controller will be fooled by the charge rate and stop the direct-charge rate too soon. The bottom line is to size your battery capacity to match your charging current.

All of the voltages listed here were found to be correct for my station's batteries and solar array. The main thing to remember is that the batteries are not fully charged when they reach 13.8 volts. We have to put more back into them than we take out. That is why the float voltage is 14.5 volts.

At night, with a small load on, the "surface charge" will be removed and the true standing voltage will be at the terminals. This will be about 12.6 volts, depending on the temperature of the electrolyte. My solar array will put into the batteries (on a cool bright day) about 11 Amps. When the batteries just start to gas, the terminal voltage is 14 volts. When the voltage hits 14.5 and the controller switches over, the specific gravity reads 1.280.

Total Solar

Fig. 4 shows the hookup into the system. Note that the battery voltage-sense wire goes directly to the battery. Don't cheat and take it off the controller supply feed. The array sense must go to the array side of the relay contact. The float regulator connects across the relay as shown.



That will finish this project. If you use the controller as a building block, expanding the system will be much simpler. A master-slave control unit would be next. To make equalizing the battery bank easier, an SPDT switch may be placed in the battery-sense line. This would select the actual battery voltage or a predefined set voltage. That way, the battery will get an overcharge and equalize its cells. A limited overcharge will be good for the batteries every now and then.

No matter how many times I watch the ammeter move up and down, the thrill I get from communicating around the world with solar energy is still beyond words. Perhaps you, too, will give it a try, now that you know how to control the power of the sun! ■

Hi Pro 'E'

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.
• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.
• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

Agc, PDQ

Take the cotton out of your ears—add automatic gain control to your Century/21.

It's happened to all of us: You're using a no-frills receiver, probably direct conversion, and you've got the gain all the way up trying to copy that weak one down in the noise, and all of a sudden—screech! A local has come on and nearly melted the headphones before you can crank the gain back down.

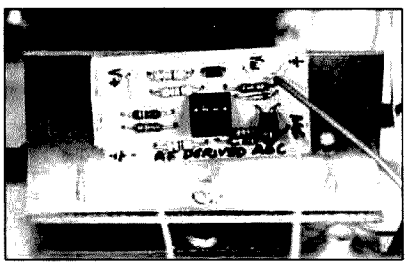

Photo A. PDQ agc circuit.

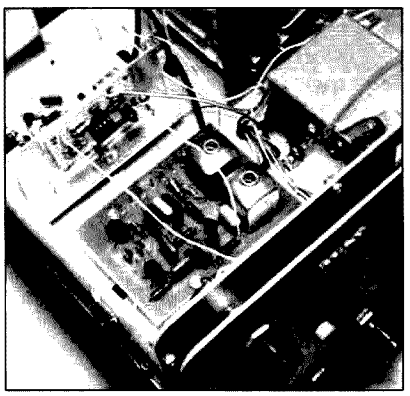

Photo B. PDQ circuit installed in a Century/21.

Well, before you throw your hands up in disgust and condemn the ol' rig to exile on the closet shelf, have a look here. All that radio needs is a little agc—and this simple circuit just may be the ticket!

Agc stands for automatic gain control, and it is just that: a feature in a receiver that automatically adjusts the gain of the receiver to keep the audio output at a fairly constant level over a wide range of signal strengths. In other words, for very weak signals the gain is adjusted higher, increasing the audio level; for strong signals, the gain is adjusted lower, decreasing the audio level.

Many of the less expensive receivers or transceivers on the market lack an agc feature, particularly the QRP radios. The Ten-Tec Century/21 is typical. I designed the "PDQ Circuit" for use in my Century/21, but with a little modification it can be used with other radios having similar configurations. It is easily built, requires very little modification to the receiver, and is simple to remove should you ever decide to restore your radio to its original condition.

Principle of Operation

There are several ways to achieve automatic gain control in a receiver. They all give the same general results, but some provide better performance than others. The strength of the signal is sampled after the filter stage

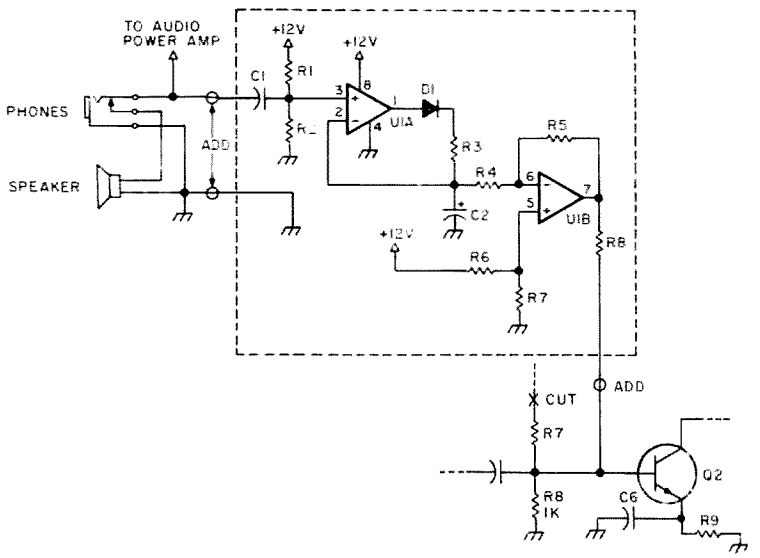

Fig. 1. Agc schematic.

Radio to Go

If you can't bear to be parted from your rig, strap on WB0WPY's VOX headset.

The term "ham radio operator" usually conjures up the image of a man sitting in some remote corner of his basement surrounded by racks of glowing equipment, puffing on his pipe while talking to some far-off exotic land, the gentle buzz of 60 cycles oozing out of every box. Occasionally he flips a switch, jots something down, or relights his pipe.

On the Go

I'm 27 and active in cycling and backpacking, so I don't fit the stereotyped image of a "ham," and I'm sure that many of you don't, either. Unfortunately, that may mean all your radio equipment is in mothballs most of the time. I have a way to let your gear see the light of day.

Solid-state equipment is ideally suited for transportation—trouble is, we still have to *operate* it, sometimes under less than ideal circumstances. Ever try to work 20m sideband while driving somewhere in a manual-shift car? If you had a headset wired to the radio, your hands would then be free to do what is most important—keeping your vehicle on the road.

A Solution

Pick up one of those personal communicator radios—that uses 49 MHz FM for short-range contacts—at most two-way radio dealers and use the headset from it. The prices I've seen range from $50 down to $22 on sale. That's not bad, especially if you've been looking at Telex prices. Even the headset from ICOM costs $40, and that doesn't have an antenna. The communicator headsets all have one earpiece, an antenna, and a boom-mounted electret condenser microphone.

Remove the headset from the radio and either file the radio parts for future projects or chuck them. There are three coax cables coming from the headset. The lead that goes "click" when you check it with an ohmmeter is the earpiece. Check for connection between the antenna rod and the remaining two coax centers, and you'll find the antenna coax that way. The one remaining is the mike (Fig. 1). Wire a 3.5 mm stereo plug on the mike and speaker wires, and a 2.5 mm plug on the antenna wire. I'll talk more about the antenna later; the headset should be all set for now.

Now make an adapter cord for your rig. If the radio doesn't have voltage on its microphone line, you'll have to modify your radio to power the mike (Fig. 2). It will still be useful for your old mike as well. If you have an extra pin on the microphone jack, run a wire to the rig's speaker. (Some radios bring speaker-level receive audio to the mike jack already; check your schematic.)

Tape Recorder to the Rescue

You're well on your way to being able to

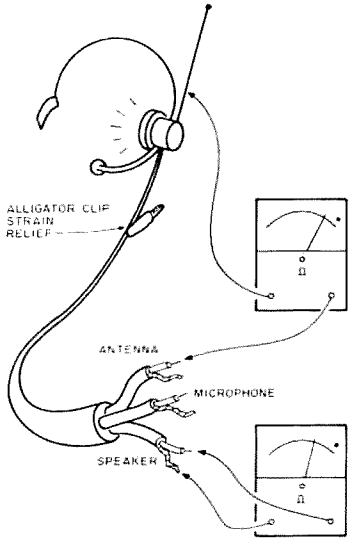

Fig. 1. Here's how to sort out which lead goes to what.

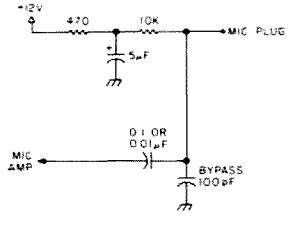

Fig. 2. You may have to bring voltage to the microphone jack.

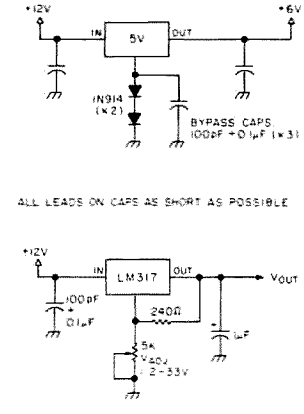

Fig. 3. Power schemes for the tape recorder.

which provides the selectivity for the receiver, and one or more of the gain stages in the receiver are adjusted to accommodate the level of signals being received at any particular instant.

Some methods sample the signal at the i-f stages, some in the audio section. The gain can be adjusted at the i-f. This particular circuit samples the signal at the audio stages, and adjusts the gain at the i-f stage. (Additional reading on the subject can be found in the references listed at the end of this article.)

The schematic in Fig. 1 shows the agc circuit added to the Century/21. Audio is taken from the headphone jack on the front panel and the peaks of the audio are detected by op amp U1A, and D1, R3, and C2. D1 rectifies the signal, and the positive peaks charge C2 through R3. The time constant of the "attack" of the agc is set by this RC network. The output of this peak detector is inverted and level-shifted by U1B so that the agc-control voltage at U1 pin 7 ranges from +6 V for no signal input to 0 V for large signals. The "decay" of the agc is determined by the RC network formed by R4 and C2.

R7 and R8 on the Century/21's front-end board set the operating bias for the i-f amplifier, Q2. This is normally fixed at +1.8 V in receive mode. Note: Before any /21 owners begin complaining, please note that the voltage chart in the owner's manual contains a typo: Q1's and Q2's values are all swapped!

By lowering the voltage on the base of Q2, its operating point can be pulled closer to cutoff, reducing its gain, until finally it will pass no signal at all. So by removing the normal voltage source by cutting at R7 as shown in Fig. 1 and adding the wire to the agc board, we have added agc to the Century/21's list of features.

The proper range of control voltage, +1.8 V to 0 V, is obtained by selecting the value of R8 on the agc board—in this case, 2.7k Ohms. This value, in conjunction with R8 on the front-end board (1 kilohm), forms a resistive divider, properly scaling the range of the control voltage.

Parts List

C1	.01 uF ceramic	Radio Shack, other sources
C2	10 uF tantalum	Radio Shack
R1, R2, R6, R7	47 kilohm, 1/4 Watt, 5%	Radio Shack
R3	1 kilohm, 1/4 Watt, 5%	Radio Shack
R4	100 kilohm, 1/4 Watt, 5%	Radio Shack
R5	220 kilohm, 1/4 Watt, 5%	Radio Shack
R8	2.7 kilohm, 1/4 Watt, 5%	Radio Shack
D1	1N914, 1N4148, etc.	Radio Shack
U1	LF412, TL084, etc.	Radio Shack

Construction

Since the circuit operates at audio frequencies, construction and parts selection is relatively noncritical. The resistor pairs R1/R2 and R6/R7 are not critical in value, but should be selected to match closely. Op amp U1 could be just about any of the common FET input types. I selected the LF412 simply because I had one in the junk box, and it had two op amps in one package. Try adjusting the values of R3 and R4 if you're of the experimental bent; the attack and hang times will change.

I mounted the circuit on the heat sink on the adjacent low-level driver board, using some of that double-sticky foam tape available at hardware stores. I used a double layer to insure against shorting through the tape. Incidentally, if you ever need to move one of those through-the-glass mobile VHF antennas, this tape is a perfect replacement for the stuff that came with the antenna.

Fig. 2 shows the foil side of a printed-circuit layout I used. On small projects like this, I generally cover the copper of a small piece of board with wide masking tape, and use a sharp knife to remove the tape where I want the copper to be etched away. It takes a steady hand and more time than it's probably worth, but it's good therapy—and what's a hobby for if not to creatively "waste" time?

Fig. 3 shows the placement of the parts for the printed-circuit layout from the component side of the board.

Operation

Operation is simplicity itself: just turn on the receiver! It is possible that when the audio gain is set very high, a noticeable "pumping" of the audio will take place. This is characteristic of audio-derived agc and would require a far more complex "cut-and-jump" to the receiver to fix. I decided to keep this project simple, and not have to perform major surgery on my radio. The cure is simply to turn the gain down until the pumping ceases. The audio level will drop very little, if at all (the agc is doing its job!), and the pumping action will disappear.

A worthwhile wrinkle to add to this project would be to put a switch on the front panel that could be used to defeat the agc when desired. An SPDT switch at the X mark on the front-end board (Fig. 1) could select between the agc and the normal circuit. Better yet, how about a switch to change the hang time by switching in different values for R4? At any rate, have fun with this project and with your new old radio! ■

run your rig in the car with hands-free VOX and a personal speaker that won't blast the wife and kiddies out of the car with the Russian Woodpecker. But you'll still want to log your contacts. I suggest an inexpensive tape recorder. Build a voltage regulator into the recorder, making sure it's well-bypassed (Fig. 3).

On the back of most ham equipment there is a jack labelled "AUX" to which is brought +12V, mike audio, receive audio (not necessarily speaker level), and so on. This can be used as the power and audio interface to your recorder.

"Ever try to work 20m sideband while driving?"

Wire it like this: The same pin on the AUX jack may be used for both receive and transmit audio to the recorder. Go downstream from the mike and find a point after the transmit audio has been amplified. Connect this point to the audio pin of the AUX jack through some high value of resistance. You'll have to experiment to find the correct value. Do the same with the receive audio (Fig. 4). You will probably end up at the speaker. With the resistors in the circuit, the receive audio shouldn't trip the VOX, even though it is connected to the transmit line, due to the high isolation provided by the resistors.

Now when you're driving down the road, you can talk to someone with your hands free, except for when you're starting and stopping the recorder. To record the time, frequency, and other information, just turn the drive all the way down on the transmitter and talk normally. The radio won't put out any power, and your voice will be recorded.

On to Two

Next, the 2m hand-held. If you want hands-free operation, you could strap your HT onto your belt and fry your kidneys. Instead, build an adapter that converts the antenna fitting of your radio to a 2.5 mm jack. Disassemble the earpiece of the headset (it usually snaps apart); inside, there is a small coil which matches the headset's antenna to 49 MHz. Bypass this with a blob of solder on the pins, and reassemble the earpiece. The antenna should be about 19 inches long, which is a good match for 146 MHz—I measured the swr on mine, and it was acceptable. On-the-air tests comparing the headset antenna with a rubber duck at waist height confirmed that the whip outperforms the duck.

Now to key the radio. ICOM suggests keying the mike ground line, but to do so would have made the headset unusable for other radios that I own (Fig. 5). I opted instead to key the positive line. I found in my junkbox a switch that fit nicely under my little finger, and wired to it a suitable length of of double-shielded wire (Fig. 6).

To keep the switch in my hand, I added some Velcro to it (Fig. 7a). Solder the braid of the coax to the switch body for strain relief and use enough wire to go up your arm and down to the radio. To keep the wire in place, I used elastic bands at the elbow and up my arm. To help with strain relief on the headset, take an alligator clip and crimp it around the wire just below the earpiece and use that to clip onto your shirt (Fig. 1). The radio goes on the belt. It's really fun to go cycling around town with this getup on. I've received some good double-takes doing this.

For the really hard-core enthusiast, you can get a mobile antenna mount, an "L" bracket, and a suitable plug, and mount everything on your external-frame backpack. A quarter-wave whip will work fine (a 5/8 will look weird) and it can double as a stainless-steel marshmallow stick. Now you can go off to the mountains, the seaside, the desert, or whatever and have emergency communications, provided you can reach a repeater. To be sure the battery doesn't freeze and die, keep it in your jacket during the day and in your sleeping bag at night.

Now all I have to figure out is how to get HBO on the Cascade Crest Trail... ■

Remote-Controlled Everything

Secure, wireless control for your next project is no longer a remote possibility.

Remote-controlled garage-door openers are becoming so common now that many people, including me, consider them as much a necessity as a toaster or lawn mower. Almost all door openers use a radio link to start the motor that raises and lowers the door.

Have you ever looked at that little transmitter clipped to the visor of your car and wondered what was inside? Maybe you opened it up (after all, you're a ham, right?) and were surprised to see only a small handful of parts. I'll bet you thought, "Gee, and they want thirty bucks for a new transmitter!"

Maybe you also started thinking of all the neat uses you could have for a small remote-control system that could reach up to 200 feet or so. How about a remote PTT switch that could key up your transmitter in the shack while you stand at the antenna with the swr meter? Or a remote TV or light control?

How about a wireless doorbell for the front gate? Or maybe a beeper in the house that alerts you when the mail arrives? The possibilities are endless. The only reason you haven't done these already is because they sounded too complicated, right? After all, you'd have to build a complete transmitter and receiver for each use.

I'm going to help you build a simple, secure radio link that can be used as the basis for a very reliable home-security system, or any other use you can think of.

Look at Fig. 1. At the left is a push-button switch that powers up the rest of the transmitter when closed. The digital-coding IC sends a serial stream of pulses to the base of a single-transistor oscillator. The oscillator turns on with a high pulse, and is off between pulses. The antenna is usually just the oscillator's inductor stretched out so that it will radiate better.

This on/off signal (just think of it as fast CW) is picked up at the receiver by a superregenerative detector. Back in earlier times, many simple receivers built by hams used superregenerative detectors. They have their limitations, which we'll talk about in a moment, but it's hard to beat a single-transistor receiver for simplicity!

The output of the detector is a demodulated audio signal that is amplified and sent to a decoder IC. If the codes selected in both the transmitter and receiver match (usually set by DIP switches), the receiver IC keys a relay that stays activated as long as the proper code is still being transmitted. The relay contacts can be used to ring a bell, fire a cannon, or whatever is desired.

Encoder/Decoder Chip

Simple, right? The system's reliability is based on the digital encoder/decoder chip's ability to make sure that only a particular code will close the relay, and not random noise or other signals coded differently. Most manufacturers of garage-door and security systems use their own proprietary coding ICs that are purposely incompatible with each other. All are based on the same principle, though.

Look at Fig. 2. This is a pinout for the National MM53200 chip. It is available from several sources, such as Jameco. Pins 1 through 12 are for setting the code you want. Twelve inputs means that you can have 2^{12}, or 4096, different codes. The connections to these pins must match in both the transmitter and the receiver. Fig. 3 shows how the connections should be made. Either a DIP switch or jumpers can be used. The IC has internal pull-ups on the code input pins, so they are either grounded for a 1 bit or left open for a 0 bit.

". . . this chip set uses trinary coding with nine bits, which gives 3^9, or 19,683, different codes possible!"

Looking at the other pins, you see a 100k resistor and a 180-pF capacitor. These two parts set the chip's internal clock frequency at about 100 kHz. Use 5% components, but do not be concerned if the clock frequencies in the transmitter and receiver do not match exactly. You would have to have at least a 15% mismatch before they wouldn't work together.

If you don't have the values specified, substitution is all right. The formula for the clock frequency is 2/RC. Other values like 47k and 470 pF are fine. You can use any other frequency, like 50 kHz, if you want, as long as the transmitter and receiver are the same. The oscillator input pin can also be driven by an external oscillator. In that case, you would delete the resistor and capacitor.

Pin 15 decides whether you have a trans-

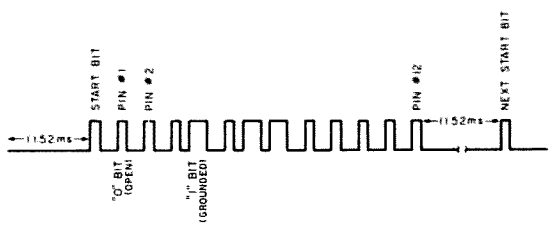

Fig. 4. Data format as sent by the transmitter chip when pins 4, 6, and 7 are grounded.

mitter or a receiver. Grounding it gives you a receiver. Connect it to the battery supply (pin 18) for a transmitter. Do not leave it open. If it is a receiver, send the data in on pin 16. If it's set up as a transmitter, the data comes out on pin 17, and pin 16 is grounded also. I recommend that you test the setup in Fig. 3 with a solderless breadboard, first. Just connect the code output, pin 17, from the transmitter to the code input, pin 16, on the receiver. Then watch the normally-high output from pin 17 on the receiver go low when the codes match. You can do that with a low-current LED or a voltmeter. Later on, this output will drive a transistor that will energize a relay.

Fig. 4 shows the nature of the data being sent and received in this system. Starting from the left, there is an 11.52-millisecond pause, then a start bit, then the twelve data bits, then another pause, then a start bit, etc. This data stream is continuous as long as the transmitter is powered up.

The start bit and twelve data bits make up one word. A word is the same length as the pause between words. The receiver chip has to see 4 words in a row that are valid (the transmitter code matches the code on the receiver switch inputs), and then pin 17 will go low. Do not try to drive an LED directly with this pin unless you use a low-current type. The pin will sink only a maximum of 2 milliamps.

There are other encoder/decoder ICs available, such as Motorola's MC145026, 27, 28, and 29. This is also second sourced from SGS-ATES. The 26 is the transmitter. There are three different receivers which vary mainly in how they treat the incoming data. The MC145028 receiver is like the MM53200 in that all of the bits are compared and a single output signals that they match. The 27 and 29 divide up either the first 4 or 5 bits as a valid address and the remaining bits as individual channel selects.

Another interesting thing is that this chip set uses trinary coding with nine bits, which gives 3^9, or 19,683, different codes possible! The code input pins are either high, grounded, or left open.

There is also a large number of TV remote-control chips from just about every IC manufacturer. These are made to operate with an infrared link, but most will work with rf. The major disadvantage with them is that they have no real security code to set, just bit patterns representing which switch on the keypad is pushed, but that shouldn't stop you from using them. Very few are used with rf links, and they are great if you need several channels with a single transmitter and receiver pair. An example would be for controlling the various movements and functions on a robot.

The Transmitter

Let's build a transmitter first. Fig. 5 shows how simple it can be. Don't be concerned if you don't have some of the exact part values specified. R1 and R2 can vary by 2:1 (don't go below 47k on R1), and I have listed most of the transistors that can work in this circuit, including one (MRF-901) that can be bought at Radio Shack. It is a real overkill for this circuit, though. If you have trouble getting parts for any of these circuits, they are available from me for a nominal cost as long as you don't want hundreds of them.

Returning to Fig. 5, we find a simple Pierce oscillator that has feedback from base to collector. Many hams don't have a solid understanding of what makes an oscillator oscillate. An oscillator is simply an amplifier tuned to the desired frequency that has some feedback from output to input.

Feedback means that a portion of the output signal is returned to the input, like the howl in a public address system when the volume is turned up too high. What happens then is that the microphone amplifies what it hears again and again. The howl is actually an amplifier being made to oscillate at the resonant frequency of the room, speakers, and microphone in combination. That's why you can get different frequency squeals by moving your hands around the mike. Your hands change the level and emphasis of frequencies heard by the mike, and therefore the pitch of the squeals you hear.

What we have to do in an oscillator is get a 360-degree phase shift through the entire circuit, and it *has* to oscillate if the transistor has enough gain. A 360-degree phase shift means that the amplified signal arrives at the base ("or collector or any other part of the loop") looking just like the signal just arriving, but delayed one full cycle.

If the fed-back signal were compared with the arriving signal on a dual-trace oscilloscope, the signals could be laid over the top of each other and they would match (except that

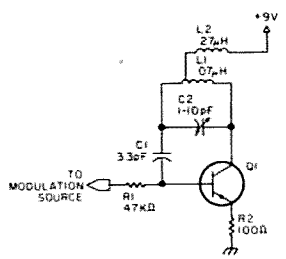

Fig. 5. The transmitter rf oscillator. Q1 can be a 2N918, 2N5179, 2N5770, 2N3563, MPSH10, MPSH11, or MRF901 (Radio Shack 276-2044).

their amplitude, or levels, wouldn't be quite the same). An old joke with rf engineers says that the sure way to build an oscillator is to design an amplifier, and vice versa! That's very true. . . feedback makes the difference.

Since we are using an NPN transistor, the base and collector are always acting oppositely, or, as the voltage rises on the base, the transistor conducts, and the voltage on the collector falls as the collector pulls more and more current. This means that the base and collector are 180 degrees out of phase, because they are acting oppositely.

Now we have half of the phase shift we need. The other half, another 180 degrees, comes from L1 and C2 in series with R1. Unless there's lots of loss through these components or the transistor doesn't have enough gain at the high frequencies we're using, the circuit should oscillate!

When you're testing this circuit, the hardest part will be finding out what frequency you're on. I'll show you how to build a simple detector to test it and make sure you're transmitting *somewhere*!

R1 and R2 are carbon film or any other type

(except wire-wound, of course). Many rf circuits specify carbon composition, and I find this to be unnecessary. Decent carbon comp. resistors are becoming harder to find, and their quality has suffered. (In the September, 1985, issue of *QEX* I go into some detail explaining this.)

C1 should be NPO for best results. NPO means that it won't change values with temperature changes. C2 can be a Radio Shack 3- to 10-pF trimmer (272-1338). L2 can be a miniature .18- to .39-microhenry choke or coil. Just take a 1/4-Watt resistor that's 1k Ohms or more and wrap 5–8 turns of small wire evenly around the body. You can use 20- to 30-gauge wire of any kind. Wire-wrap wire is fine, too.

LI is simply a hairpin loop of wire of any gauge. Heavier wire will be more stable. I recommend 12- to 14-gauge house wiring with the insulation removed. The same applies to the receiver's L1 inductor. Start out with a straight piece of wire about 3 inches long and bend it in half around your little finger like a large hairpin. A circle is all right, too. The real trick in this circuit is to get it as mechanically stable as possible.

Ideally, L1 should be a printed-circuit trace about .025 inches wide with C2's leads going through holes in the PC board, soldered across LI. You might try tacking your inductor to an unclad (no copper on either side) portion of your PC board with super glue in several places. The circuit will drift all over the place unless you get LI and C2 so they don't move when you go to tune C2. You should also mount the transmitter in a plastic case, such as Radio Shack's 270-291. It also comes with its own perfboard.

Component-mounting methods are up to you. The simplest is just to tack-solder the component leads to each other over a small square of unetched PC board. The components that go to ground form the mounting feet for the circuit. Keep all component lead lengths to ¼ inch or so.

L2 should be tapped on L1 about 25% of the way from the transistor base. Too close to the base, and it won't oscillate. Too far, and it gets less stable. If you've bent L1 into a hairpin shape, just put the top halfway between the bend and the base, then move just a little back towards the bend for good luck. Better to be a little unstable than not to oscillate.

To test the circuit, tie R1 to 9 volts temporarily. The circuit should draw about 5-10 mA from the battery. Now you have a CW oscillator that is probably oscillating somewhere between 180 and 500 MHz. Most garage-door-opener radios are between 290 and 400 MHz. Unless you have a spectrum analyzer (about $12,000), you won't know where you are. The circuit in Fig. 6 is a simple diode detector to show you that you're oscillating somewhere. At this point, that's all you need to know.

If you have cable TV, you can stick a short antenna into the cable converter or cable-ready TV's input, tune it to channels K or 24 (223–25 MHz) through X or 37 (301–25 MHz). Tune C1 through its full range, and at some point you should see a change in the picture or sound of the TV. Shorten or lengthen L1 if you get nothing. Please use an insulated tool. It's frustrating to watch your signal drift off as you pull your Craftsman screwdriver away. It could also cause your circuit to stop working.

The same tuning procedure applies with the diode detector. The pickup loop may have to be almost in contact with LI before you get an indication. The most you'll see is about 2 to 7 volts. Any indication at all shows that you are transmitting. If you're in doubt about the detector, try it carefully with your 2-meter rig or HT. You'll see a lot more indication with the higher power gear.

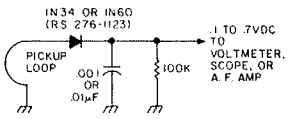

Fig. 6. The diode detector will give an indication that the transmitter is working. The pickup loop should be one turn about the same size as the transmitter loop, or larger. Use a dc voltmeter on a 2-volt scale, or a scope. An audio amplifier will work if the transmitter signal is modulated.

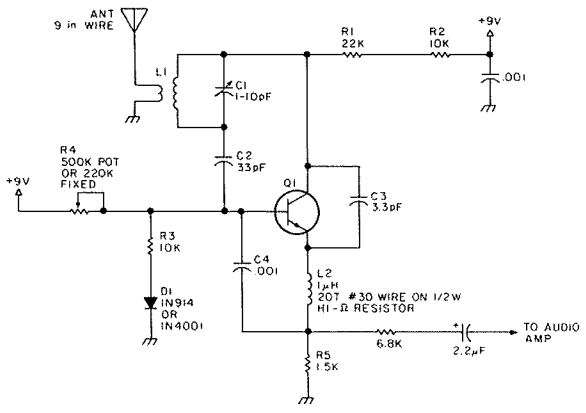

Fig. 7. The receiver. Q1 is the same transistor as is used in the transmitter. Experiment with the antenna and its coupling loop only after you have the receiver working. You should still get 100 feet or so of range just using L1 by itself.

"Although the likelihood of the radio police descending on your house is extremely small, it is your responsibility to make sure that you do not interfere with anything else."

Now that you have your transmitter working, smile smugly at your abilities and go to work on the receiver. You might also connect R1 to pin 17 of your code-transmitter chip and observe the code being sent on an oscilloscope connected to your diode detector. Or you could connect the detector to an audio amplifier and hear the musical buzz the code chip makes. It may also make some interesting viewing on your television!

A Super- What?

Superregenerative detectors are still used today in a variety of things such as radar transponders, aircraft altitude-measuring radar, police radar detectors, inexpensive radio-controlled toys and walkie-talkies, and garage-door-opener receivers. The main reason they are used is because of cost and circuit complexity; it's hard to beat a one-transistor receiver. Their main disadvantages are that they are limited mostly to AM and pulse detection. They also tend to emit quite a bit of rf. This can be controlled somewhat by isolating the detector stage from the antenna with a preamp.

Looking at Fig. 7, you might think that you're looking at an oscillator circuit. We have the Pierce-type tuned circuit connecting between the base and collector of Q1, just like the transmitter we built. The main difference here is that we connect C4 into the circuit and it, along with L2, R3, and R4, form another low-frequency oscillator at about 200 to 700 kHz. If you have the interest, you could disconnect C4 and observe that you now have a single frequency oscillator just like the transmitter.

A superregenerative detector is basically an oscillator that is rapidly turned on and off. This circuit turns *itself* on and off, so we call it a self-quenching detector. You could also turn it off and on externally with a sine- or sawtooth-wave generator connected to the transistor base through a small choke. Square waves are not desired here as they spend little time in transition (the time between fully on, or a logic high, and fully off, or ground). During the transition period, and when the transistor just begins to conduct, amplifica-

tion of an incoming signal is achieved on the order of a *million* times, or more! That's why we can get such good sensitivity from a single amplifier stage.

The receiver in Fig. 7, although not the best, can hear signals as low as 3 to 5 microvolts. Adding a preamplifier (even a $10.00 Radio Shack TV amplifier) will help increase sensitivity and also cut down on detector radiation through the antenna. For long-term use, I recommend doing this and also putting the entire receiver in a shielded enclosure.

Why not use a superheterodyne receiver, with sensitivity down in the .2-to-.5-microvolt range? Cost, complexity, and attention to the vagaries of careful rf layout come to mind. Also, you don't need the narrow bandwidth achievable with the superhet here. The transmitter will drift as much as 2 MHz under handling and tuning, and you're going to have enough concern just finding the transmitter signal at first. You don't need razor-sharp tuning right now.

Building the Receiver

Let's look at Fig. 7 again. L1 is another loop of stiff wire, or firmly mounted smaller gauge. The antenna and its coupling loop shown in the schematic are optional. The coupling loop should be another single turn lying next to L1 on the PC board about ¼ to ½ inch away. I recommend you just worry about L1 initially, and experiment with the antenna later. The pot, R4, can be replaced with a fixed resistor after setting the quench frequency to about 300–600 kHz, as measured by a scope or frequency counter at the junction of R1 and R2. That's why we have the two resistors there instead of a single 33k resistor.

If you don't have a scope or counter, you can still make this circuit work fine. You'll need a medium- or high-impedance audio amplifier. I recommend one anyway, and I even use one myself. I have a little box with an LM-386 IC and a 9-volt battery. You could do a lot worse than the one Radio Shack sells for $11.95 (227-1008). It's the same thing, basically.

Connect the amplifier up to the audio output point shown as you tune R4 through its range. C1 should also be turned if nothing happens, or put it in the center of its range. You are listening for the characteristic rushing noise, or hiss, that tells you the detector is oscillating. If you hear nothing, touch the transistor base with your finger. If you don't hear a slight hum or squeal, then there is something wrong with the dc connections of the transistor, such as R4, R3, D1 (it's not backwards, is it?), L2, R5, or R1 and R2. Or maybe the transistor itself is connected wrong.

You may hear squeals and burps, but somewhere you'll hear the hiss. You might also try shortening or lengthening L1, which is just about the same size as L1 in the transmitter. If you turn on your unmodulated transmitter, the hiss will suddenly quiet down as it's tuned to the receiver. If you connect up your code-generating chip to the transmitter as I suggested, you'll hear the musical buzz in the receiver. At this point you have a working receiver.
